Optimum temperature 30°C. Maximum 39°C. Minimum 8°C.

Optimum pH 6.0 to 8.0. Limits about pH 4.5 to 8.5.

8 per cent salt restricts growth.

Strict aerobe.

Source: From wilted sweet corn.

Habitat: Pathogenic on corn, *Zea mays*. Sweet corn very susceptible and field corn slightly so.

46. **Bacterium tardicrescens** McCulloch. (McCulloch, Phytopath., *27*, 1937, 135; *Phytomonas tardicrescens* Burkholder, Phytopath., *27*, 1937, 617.) From Latin, slow growing.

Rods: 0.6 to 0.8 by 1.58 microns. Motile with a polar flagellum. Gram-negative.

Gelatin: No liquefaction.

Beef-extract agar colonies: Circular, mustard yellow, edges entire, 1 to 1.5 mm in diameter.

Broth: Light clouding.

Milk: Slightly alkaline. Clearing after 5 to 6 weeks.

Nitrites are produced from nitrates.

Indole not produced.

No H_2S produced or feebly so.

Acid but no gas from glucose, fructose, galactose, arabinose, xylose and rhamnose. Alkaline reaction from salts of citric, malic and succinic acid.

Starch is not hydrolyzed.

Not lipolytic (Starr and Burkholder, Phytopath., *32*, 1942, 603).

Optimum temperature 26°C. Maximum 32°C. Minimum 5°C (McCulloch. Phytopath., *28*, 1938, 648).

Optimum pH 6.5 to 7.5. Growth slight at 5.8 and 8.0 (McCulloch, *loc. cit.*).

No growth with 3 per cent salt (McCulloch, *loc. cit.*).

Aerobic.

Distinctive character: Very slow grower.

*The section covering species of interest to plant pathologists has been prepared by Prof. Walter H. Burkholder, Cornell Univ., Ithaca, New York, May, 1946.

Source: Isolated by McCulloch and by Burkholder from blighted iris leaves.

Habitat: Pathogenic on *Iris spp.*

47. **Bacterium albilineans** Ashby. (Ashby, Trop. Agr., Trinidad, *6*, 1929, 135; *Phytomonas albilineans* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 326.) From Latin, producing white streaks.

Description taken from Martin, Carpenter and Weller, The Hawaiian Planters' Record, *36*, 1932, 184.

Rods: 0.25 to 0.3 by 0.6 to 1.0 micron, occurring singly or in chains. Motile with a polar flagellum. Grám-negative.

Agar colonies: After 7 to 10 days, minute transparent drops, moist, shining. Honey yellow to Naples yellow.

Gelatin: No liquefaction.

Milk: Growth, but no visible change in the milk.

No growth with ammonium salts, nitrates, or asparagine as a source of nitrogen.

No growth in peptone water without carbohydrates. Invertase secreted.

Starch is not hydrolyzed.

Optimum temperature about 25°C. Maximum 37°C.

Distinctive characters: Differs from *Xanthomonas vascularum* which produces a large gummy type of colony, and which is a very active organism biochemically. The two pathogens also differ in the type of lesion they produce on sugar cane.

Source: Isolated by D. S. North (Colonial Sugar Ref. Co., Sidney, N.S. Wales, Agr. Rept., *8*, 1926, 1) from white stripe and leaf scald of sugar cane in Australia.

Habitat: Vascular pathogen of sugar cane, *Saccharum officinarum.*

Appendix I: The following species have been described from diseased plant tissues but may not, in some cases at least, have been the cause of the disease.

Bacillus betae Migula. (Kramer, Oesterreich. landwirtsch. Centralb., 1891, Heft 2 and 3; Migula, Syst. d. Bakt., *2*, 1900, 779.) The cause of a disease of the sugar beet (*Beta vulgaris*).

Bac. caryophyllacearum Dufrenoy. (Compt. rend. Soc. Biol., Paris, *81*, 1918, 920; probably there is an earlier reference to this species.) On *Dianthus, Saponaria* and *Lychnis.*

Bacillus coffeicola Steyaert. (Rev. Zoo. et Bot. Afr., *22*, 1932, 137.) From nodules on coffee roots.

Bacillus lacerans Migula. (*Bacillus* α, Busse, Ztschr. f. Pflanzenkr., *7*, 18—, 72; Migula, Syst. d. Bakt., *2*, 1900, 780.) From diseased sugar beets.

Bacillus maculicola Delacroix. (Delacroix, Compt. rend. Acad. Sci. Paris, *140*, 1905, 680; *Bacterium maculicola* Stapp, in Sorauer, Handb. d. Pflanzenkrankheiten, 5 Aufl., *2*, 1928, 276; *Aplanobacter maculicola* Elliott, Manual Bact. Plant Path., 1930, 8; *Phytomonas nicotianae-tabaci* Magrou, in Hauduroy et al., Dict. d. Bact. Path., 1937, 386.) From diseased spots on leaves of tobacco.

Bac. nucleophyllus Dufrenoy. (Compt. rend. Soc. Biol., Paris, *81*, 1918, 920, *nomen nudum.*) On *Rhododendron ferrugineum.*

Bac. tritici Dufrenoy. (Compt. rend. Soc. Biol., Paris, *81*, 1918, 920, *nomen nudem*; not *Pseudomonas tritici* Hutchinson, India Dept. of Agr., Bact. Ser., *1*, 1917, 174.) On wheat.

Bacillus vitis Montemartini. (Rev. Patol. Veg., *6*, 1913, 175.) Pathogenic on the grape (*Vitis vinifera*).

Bacterium apii Brizi. (Lav. e Relaz. d. Reg. Staz. di Patol. Veg., Roma, Gennio-Giugno, 15, 1896 and Atti R. Accad. Naz. Lincei, Rend. Cl. Sc. Fis., Math. e Nat., Ser. 5, *6*, 1897, 233.) Motile. From rot of celery.

Bacterium betae Chester. (Bacterial parasite, Arthur and Golden, Indiana Agr. Exp. Sta., Bull. 39, 1892, 61; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 128; *Bacillus arthuri* Migula, Syst. d. Bakt., *2*, 1900, 681.) Motile. From diseased sugar beet tubers.

Bacterium briosianum Pavarino.

(Atti del. R. Accad. Naz. Lincei, Rend. Cl. Sci. Fis., Math. et Nat., *20*, 1911, 161.) Motile. From lesions on the vanilla vine.

Bacterium castinicolum Cavara. (Rev. d. Pat. Veg., *7*, 1914, 5.) Motile. From chestnut canker.

Bacterium corylii Brzezinski. (Bull. Intern. Acad. des Sci. Cracovie, Cl. Sci. Math. e Nat., 1903, 139.) Motile. From diseased filbert trees.

Bacterium dendrobii Pavarino. (Rev. di Pat. Veg., *5*, 1912, 242.)

Bacterium dianthi Chester. (Parasitic bacteria, Arthur and Bolley, Purdue Univ. Agr. Exp. Sta., Bull. 59, 1896, 21; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 106; *Bacillus dianthi* Chester, Man. Determ. Bact., 1901, 253; *Pseudomonas dianthi* E. F. Smith, U. S. Dept. Agr., Div. Veg. Phys. and Path., Bull. 28, 1901, 153.) Motile. From lesions on carnation leaves.

Bacterium fici Cavara. (Ist. Bot. del. R. Univ. di Catania, Atti Acad. Gioen., *18*, Mem. 14, 1905, 1; *Phytomonas* (?) *fici* Magrou, in Hauduroy et al., Dict. d. Bact. Path., 1937, 354.) Motile. Causes a blight of figs.

Bacterium lycopersici var. *vitiati* Strzalkowska. (Strzalkowska, Acta Soc. Bot. Poloniae, Warsaw, *7*, 1930, 611; *Phytomonas vitiati* Burkholder, in Manual, 5th ed., 1939, 216.) From rotting tomato.

Bacterium mali Brzezinski. (Bull. Intern. Acad. Sci. Cracovie, Cl. Sci. Math. e Nat., 1903, 100.) Motile. From apple canker.

Bacterium montemartinii Pavarino. (Rev. di Pat. Veg., *5*, 1911, 65.) Motile. From wisteria canker.

Bacterium (?) *oncidii* Peglion. (Peglion, 1899, quoted from Hauduroy et al., Dict. Bact. Path., 1937, 388; *Bacillus oncidii* Stevens, 1913; *Phytomonas* (?) *oncidii* Hauduroy et al., *idem.*) From an orchid (*Oncidium sp.*).

Bacterium pini Chester. (Bacillus des tumeurs du Pin d'Alep, Vuillemin, Compt. rend. Acad. Sci., Paris, *107*, 1888, 874 and 1184; *Bacillus vuillemini* Trevisan, I generi e le specie delle Batteriacee, 1889, 19; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 127; *Pseudomonas pini* Petri, Ann. Ist. Supt. For. Naz. Firenze, *9*, 1924, 187.) From galls on pine (*Pinus halepensis*).

Bacterium putredinis Davaine. (Davaine, Bactéries, in Dictionnaire Encyclopédique des Sci. Médicales, 1866; *Bacillus putredinis* Trevisan, Add. ad Gen., p. 36; see DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1025; not *Bacillus putredinis* Weinberg, Nativelle and Prévot, Les Microbes Anaérobies, Paris, 1937, 755.) Causes a soft rot of several plants.

Bacterium pyri Brzezinski. (Bull. Internat. d. l'Acad. des Sci. de Cracovie, Cl. Sci. Math. e Nat., 1903, 130.) Motile. From pear canker.

Bacterium rubefaciens Burr. (Burr, Ann. App. Biol., *15*, 1928, 570; *Phytomonas rubefaciens* Magrou, in Hauduroy et al., Dict. Bact. Path., 1937, 406; not *Bacterium rubefaciens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 115.)

Bacterium suberfaciens Burr. (Burr, Ann. App. Biol., *15*, 1928, 570; *Phytomonas suberfaciens* Magrou, in Hauduroy et al., Dict. Bact. Path., 1937, 417.) Motile. From diseased potato tubers.

48. **Bacterium rubefaciens** (Zimmermann) Chester. (*Bacillus rubefaciens* Zimmermann, Die Bakterien unserer Trink- und Nutzwässer, Chemnitz, *1*, 1890, 26; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 115; *Erythrobacillus rubefaciens* Holland, Jour. Bact., *5*, 1920, 223; *Serratia rubefaciens* Bergey et al., Manual, 1st ed., 1923, 92; *Chromobacterium rubefaciens* Topley and Wilson, Princ. Bact. and Immun., *1*, 1931, 402.)

From Latin *ruber*, red and *facio*, to make.

Rods: 1.0 to 1.6 microns in length, occurring singly and in pairs. Actively motile. Gram-negative.

Gelatin colonies: Minute, white.

Gelatin stab: Surface growth yellowish, the medium taking on a red tinge. No liquefaction.

Agar colonies: Small, white, with erose margin.

Agar slant: White, smooth, glistening, somewhat luxuriant, the medium taking on a wine red color.

Broth: Turbid with white pellicle, the medium slowly assuming a reddish tinge.

Litmus milk: Acid, with slow coagulation and reduction of the litmus. Becoming alkaline.

Potato: A heavy, white, creamy layer, which later becomes yellowish-brown.

Indole not produced.

Nitrites produced from nitrates.

Aerobic, facultative.

Optimum temperature 25°C. No growth at 37°C.

Habitat: Water.

49. **Bacterium rubidum** (Eisenberg) Chester. (*Bacillus rubidus* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 88; *Bacterium rubidus* (sic) Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 107 and 115; *Serratia rubida* Levine and Soppeland, Iowa State Coll. Engineering Exp. Sta. Bull. 77, 1926, 53.) From Latin *rubidus*, red.

Description from Eisenberg (*loc. cit.*). Levine and Soppeland (*loc. cit.*) found an organism in buttermilk which they identified as *Serratia rubida*. Their description is more complete than that given by Eisenberg but differs from the original in several respects.

Rods: Medium size with rounded ends, often in long chains. Motile.

Gelatin colonies: Circular, finely granular, entire, with reddish center. Slow growth.

Gelatin stab: Liquefaction. Brownish-red sediment.

Agar colonies: Small, flat, smooth, amorphous, entire, brownish-red. Slow growth.

Agar slant: Brownish-red streak. Spreading over surface.

Potato: Brownish-red growth.

Blood serum liquefied, red pigment.

Aerobic, facultative.

Does not grow well at 37°C.

Source: Water.

50. **Bacterium latericeum** (Adametz) Lehmann and Neumann. (*Bacillus latericeus* Adametz, Die Bakterien der Trink- und Nutzwässer, Mitteil. der oestrr. Versuchsanst. f. Brauerei u. Mälzerei in Wien, 1888, 50; *Bacillus erythraeus* Trevisan, I generi e le specie delle Batteriacee, 1889, 19; *Bacterium latericeum* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 258; *Serratia latericea* Bergey et al., Manual, 1st ed., 1923, 94.) From Latin *latericeus*, brick.

Rods: 0.5 to 0.7 by 1.0 to 1.3 microns. Non-motile. Gram-negative.

Gelatin colonies: Small, white, granular, with slightly irregular margin.

Gelatin stab: A thin, dry, spreading, cream-pink surface growth. No liquefaction.

Agar colonies: Dry, glistening, whitish, with irregular margin.

Agar slant: Brick-red, smooth, glistening, butyrous.

Broth: Thick pellicle; fluid clear.

Litmus milk: Alkaline.

Potato: Brick-red streak.

No gas from carbohydrate media.

Indole not produced.

Nitrites produced from nitrates.

Aerobic, facultative.

Optimum temperature 25° to 30°C.

Habitat: Water.

51. **Bacterium alginicum** Waksman, Carey and Allen. (Jour. Bact., 28, 1934, 213.)

Rods short to almost spherical, 0.6 to 1.0 micron in diameter. Sluggishly motile. Capsule-forming. Gram-negative.

Alginic acid plate: White, finely granulated colonies, with entire margin. Does not clear up the turbidity in plate. Odor formed, resembling that of old potatoes.

Alginic acid liquid medium: Thin pellicle, weak alginase formation.

Sea water gelatin: Thin growth throughout gelatin stab, no liquefaction in 7 days at 18°C.

Agar liquefaction: None.

Sea water glucose broth: Uniform but

very limited turbidity; no pellicle; no sediment.

Litmus milk containing salt: No apparent growth.

Potato moistened with sea water: Moist, spreading growth, cream-colored; heavy sediment in free liquid at bottom.

Starch plate: Limited, pale blue growth; no diastase.

Aerobic.

Optimum temperature 20°C.

Source: From sea water, and from the surface of algal growth.

Habitat: Common in sea water.

52. **Bacterium terrestralginicum** Waksman et al. (Waksman, Carey and Allen, Jour. Bact., *28*, 1934, 217.)

Long rods, with somewhat rounded ends, usually single, but also in pairs, and occasionally in chains of shorter rods. 1.0 to 1.5 by 1.5 to 2.5 microns. Motile. Granular. Gram-negative.

Alginic acid plate: Colonies small, whitish in appearance with a slight metallic sheen.

Alginic acid liquid medium: Medium at first clouded. Later, a pellicle is formed on the surface of the medium, which is soon broken up due to active gas formation. Reaction of medium becomes slightly alkaline.

Gelatin medium: Slow growth throughout stab, slow liquefaction at surface of medium at 18°C.

Agar liquefaction: None.

Glucose broth: Abundant turbidity, some sediment, no pellicle, slightly fluorescent.

Litmus milk: Acid, milk coagulated, only limited digestion of coagulum.

Potato: Abundant, pinkish, compact, dry growth on surface of plug, the rest of plug becoming gray, with a tendency to darkening.

Starch plate: Limited growth along streak, no diastase.

Aerobic to facultative anaerobic.

Optimum temperature 30°C.

Source: From New Jersey soil.

Habitat: Soil.

53. **Bacterium cygni** Migula. (Septikämiebacillus der Schwäne, Fiorentini, Cent. f. Bakt., *19*, 1896, 935; Migula, Syst. d. Bakt., *2*, 1900, 365; *Bacillus cygneus* Chester, Manual Determ. Bact., 1901, 221.) From Latin *cygnus*, swan.

Rods: Motile. Gram-negative.

This organism may have been the fowl cholera or septicemia organism (*Pasteurella avicida* Trevisan); but is more probably closely related to the organism which causes keel in ducklings (*Salmonella anatis* Rettger and Scoville).

Source: From a swan.

Habitat: The cause of an infectious disease of swans in the city park at Milan, Italy in 1895.

54. **Bacterium cyprinicida** Plehn. (Plehn, Cent. f. Bakt., I Abt., Orig., *35*, 1903–04, 461; *Klebsiella cyprinicida* Bergey et al., Manual, 2nd ed., 1925, 266.) From Greek *kyprmos*, carp and Latin *caedo*, to kill.

Rods: 0.8 by 1.0 micron, occurring singly and in chains. Capsulated. Non-motile. Gram-negative.

Gelatin colonies: White, glistening, convex, with slight fluorescence around the colony in three or four days.

Gelatin stab: White, convex surface growth. No liquefaction.

Agar slant: White, glistening layer, becoming slimy.

Broth: Turbid, with thick gray pellicle and slimy sediment.

Litmus milk: Slightly alkaline. No coagulation.

Potato: Light yellowish layer, becoming dark brownish. The medium is dark violet-gray.

Indole not formed.

Nitrites not produced from nitrates.

No acid from carbohydrate media.

Aerobic, facultative.

Optimum temperature 10° to 20°C.

Habitat: The cause of a fatal disease in carp, showing as red spots on the ventral surface.

55. **Bacterium parvulum** Conn. (N. Y.

Agr. Exp. Sta. Bul. 494, 1922, 26.) From Latin, very small.

Very small rods: 0.1 to 0.2 by 0.3 to 0.5 micron. Non-motile. Gram-negative.

Gelatin plate: Punctiform colonies.

Agar plate: Punctiform colonies.

Grows poorly in liquid media.

Indole not formed.

Nitrites produced from nitrates.

No acid from glucose, lactose, sucrose, glycerol or ethyl alcohol in either liquid or solid media.

Starch not digested.

Optimum temperature 25°C.

Strictly aerobic.

Distinctive character: Causes strong volatilization of ammonia from a mixture of horse feces and urine.

Source: From manure.

Habitat: Soil.

56. **Bacterium methylicum** (Loew) Migula. (*Bacillus methylicus* Loew, Cent. f. Bakt., *12*, 1892, 465; Migula, Syst. d. Bakt., *2*, 1900, 447.) From the chemical term, methyl.

Short, thick rods: 1.0 by 2.0 to 2.5 microns. Gram stain not recorded.

Gelatin colonies: After 2 days, round to oval, yellowish, entire; later edges ciliate. Liquefaction.

Glucose gelatin stab: Liquefaction crateriform. Whitish-yellowish sediment. No liquefaction in depth.

Glucose gelatin stab: In depth, little or no growth, slowly liquefied near surface.

Agar stab: Surface growth spreading, grayish-white. No growth in depth.

Broth: No turbidity. On the surface and adherent to the walls, a white ring which precipitates on shaking.

Potato: Growth very slow, pure white, adherent.

Grows well in 0.5 per cent methyl alcohol, 0.05 per cent dicalcium phosphate, and 0.01 per cent magnesium sulfate, on which broth it forms a reddish pellicle.

Possesses the ability to decompose formaldehyde and formic acid salts with formation of a reddish pellicle.

Aerobe.

Source: A culture contamination from the air.

Habitat: Probably soil.

Appendix I: A few of the numerous Gram-negative, motile or non-motile, non-spore-forming rods that do not belong in the groups previously listed in this genus are described here. All have been placed in the genus *Bacillus* by those who have described them, although none form spores.

I. Produce a pink to red chromogenesis.
  A. Motile.
    1. *Bacillus lactorubefaciens.*
  B. Non-motile.
    1. Gelatin liquefied.
      2. *Bacillus rubricus.*
      3. *Bacillus rufus.*
    2. Gelatin not liquefied.
      a. Salmon pink on agar.
        4. *Bacillus mycoides corallinus.*
      aa. Vinous red on agar.
        5. *Bacillus bruntzii.*
II. Produces a water-soluble orange to emerald green pigment.
  A. Motile.
    1. Gelatin liquefied.
      6. *Bacillus aurantiacus tingitanus*

1. **Bacillus lactorubefaciens** Gruber. (Gruber, Cent. f. Bakt., II Abt., *8*, 1902, 457; *Serratia lactorubefaciens* Bergey et al., Manual, 1st ed., 1923, 92.) From Latin, to make milk red.

Small rods: 0.4 to 0.6 by 3.5 microns, occurring singly and in pairs. Motile with peritrichous flagella. Gram reaction not given.

Gelatin colonies: Grayish-white, smooth, glistening, spreading.

Gelatin stab: At times arborescent; the medium tinged with red. No liquefaction.

Agar colonies: Circular, lobed, grayish, contoured.

Agar slant: White, spreading growth.

Broth: Turbid, with grayish pellicle and slimy sediment.

Limus milk: Becomes rose red, slimy, slightly acid, without coagulation.

Potato: White, spreading growth.

No gas from carbohydrate media.

Indole not produced.

Nitrites produced from nitrates.

Aerobic, facultative.

Optimum temperature 25°C.

Habitat: Milk.

2. **Bacillus rubricus** Hefferan. (Hefferan, Cent. f. Bakt., II Abt., *11*, 1903, 403; *Erythrobacillus rubricus* Holland, Jour. Bact., *5*, 1920, 220; *Serratia rubrica* Bergey et al., Manual, 1st ed., 1923, 313; *Chromobacterium rubricum* Topley and Wilson, Princ. Bact. and Immun., *1*, 1931, 402.)

Rods: 0.7 to 0.9 by 1.0 to 4.0 microns, occurring singly. Non-motile. Gram reaction not given.

Gelatin colonies: Small, circular, yellow-orange, deepening to red.

Gelatin stab: Slow liquefaction. Old cultures lose this property.

Agar colonies: Circular, raised, entire.

Agar slant: Moist, spreading, white to pink, gradually deepening in color.

Broth: Turbid, with viscid sediment.

Litmus milk: Alkaline.

Potato: Slight growth, bright pink, turning coral red.

Indole not produced.

Nitrites not produced from nitrates.

No acid or gas from carbohydrate media.

Aerobic, facultative.

Optimum temperature 25° to 30°C. No growth at 37°C.

Source: Isolated from Mississippi river water, also from buttermilk.

3. **Bacillus rufus** Hefferan. (Hefferan, Cent. f. Bakt., II Abt., *11*, 1903, 313; *Erythrobacillus rufus* Holland, Jour. Bact., *5*, 1920, 220; *Serratia rufa* Bergey et al., Manual, 1st ed., 1923, 95.) From Latin *rufus*, red.

Differs from *Bacillus rubricus* in showing more luxuriant growth on potato and slower action in milk.

Source: From Mississippi River water.

4. **Bacillus mycoides corallinus** Hefferan. (Hefferan, Cent. f. Bakt., II Abt., *11*, 1903, 459; *Serratia corallina* Bergey et al., Manual, 1st ed., 1923, 93.)

Small, slender rods: 1.2 to 2.0 microns in length, occurring singly and in pairs. Non-motile. Gram reaction not given.

Gelatin colonies: Minute, becoming pink, smooth, raised.

Gelatin stab: Slow growth. Raised, smooth, glistening, pink surface growth. Fine, feathery growth in stab. No liquefaction.

Agar colonies: Minute, with filamentous margin.

Agar slant: Smooth, moist, salmon pink.

Broth: Turbid, with pink flakes on surface.

Litmus milk: Alkaline, with red surface.

Potato: Like agar slant.

Indole not formed.

Nitrites produced from nitrates.

No gas from carbohydrate media.

Aerobic, facultative.

Optimum temperature 25° to 30°C.

Source: Isolated from Mississippi river water.

5. **Bacillus bruntzii** Nepveux. (Nepveux, Compt. rend. Soc. Biol., Paris, *72*, 1920, 242; Thèse, Fac. de Pharm., Jouve et Cie, Paris, 1920, 136 pp.; *Serratia bruntzii* Bergey et al., Manual,

3rd ed., 1930, 125.) Named for Prof. Bruntz of Paris.

Bacillus roseus fluorescens Marchal (Trav. Lab. Microbiol. Fac. Pharm. Nancy, 1937, 90) is regarded by Lasseur (personal communication, 1938) as identical with *Bacillus bruntzii* Nepveux.

Rods: 0.3 to 0.5 by 1.25 to 1.5 microns, occurring singly and in pairs. Non-motile. Gram-negative. The cells store volutin and glycogen as reserve materials.

Gelatin colonies: Circular, gray, smooth, contoured, glistening, undulate margin, becoming red.

Gelatin stab: No liquefaction.

Agar colonies: Circular, flat, smooth, contoured, radiate margin, vinous red.

Agar slant: Smooth, echinulate, butyrous, vinous red in color.

Broth: Turbid.

Litmus milk: Unchanged.

Indole not formed.

Nitrites produced from nitrates.

Acid from glucose, fructose, maltose, lactose, sucrose, mannitol, dulcitol and glycerol.

Aerobic, facultative.

Optimum temperature 20° to 25°C.

Habitat: Water.

6. **Bacillus aurantiacus tingitanus** Remlinger and Bailly. (Compt. rend. Soc. Biol. Paris, *119*, 1935, 246.)

Short rods: Usually 2 to 3 microns, sometimes 5 to 6 microns long. Actively motile. Gram-negative.

Growth occurs on all the ordinary nutrient media. Fluorescent bright orange pigment.

Gelatin: Rapid liquefaction.

Milk: Slow coagulation.

Synthetic broth: Lasseur, Dupaix-Lasseur and Marion (Trav. Lab. Microbiol. Fac. Pharm. Nancy, Fasc. 9, 1936, 34) recognize two rough types of this organism, one of which forms a smooth and the other a wrinkled pellicle. The smooth type gives a rough (pH 4.7) or a smooth (pH 6.3) pellicle according to the pH of the medium.

Indole not formed.

Artichoke media: Luxuriant growth. Emerald green pigment produced. On transferring the culture to potato, the bright orange pigment reappears.

Coagulated serum: No liquefaction.

Acid from sucrose, lactose, glucose, mannitol and maltose.

Non-pathogenic.

Optimum pH 6.6. No growth at pH 6.2, but grows at pH 7.8.

Optimum temperature 20°C. Good growth from 15° to 37°C.

Aerobic.

Pigment: Orange or capucine pigment which diffuses throughout the medium. Not affected by the presence or absence of light. Pigment production depends on the growth of the culture, not on the acidity of the medium. Insoluble in acetone, amyl alcohol and gasoline. Partially soluble in ether and ethyl alcohol which are colored yellow.

Distinctive character: A fluorescent pigment of an unusual shade (bright orange).

Source: From water at Tangiers.

Habitat: Presumably water.

Appendix II:* The anaerobic genus *Methanobacterium* was proposed tentatively by Kluyver and Van Niel in 1936 with indication that they regarded Söhngen's methane bacterium as the type species of the genus. Later, Barker (1936) found organisms that he regarded as identical with those previously isolated by Söhngen and he proposed the name *Methanobacterium söhngenii* for this species. A second species found at the same time was named *Methanobacterium omelianskii* and it was identified as the species previously described but not named by Omeliansky. At the time, he felt that these anaerobes should be included in the family *Mycobacteriaceae* (1936,

* The manuscript for this section has been reviewed by Dr. H. Albert Barker, University of California, Berkeley, California, February, 1945.

p. 422). In 1940, he discovered that the second species produced spores. In a personal communication (March 20, 1945) he suggests that further work is needed before the relationships of these organisms can be clarified.

Genus A. **Methanobacterium** *Kluyver and Van Niel.*

(Cent. f. Bakt., II Abt., *94*, 1936, 399.)

Straight or slightly bent rods, sometimes united in bundles or long chains. Usually non-motile. Endospores sometimes formed. Anaerobic. Chemo-heterotrophic or chemo-autotrophic oxidizing various organic or inorganic compounds and reducing carbon dioxide to methane. Gram-variable, usually negative.

The type species is *Methanobacterium soehngenii* Barker.

1. **Methanobacterium soehngenii** Barker. (Methane bacterium, Söhngen, Dissertation, Delft, 1906; Barker, Arch. f. Mikrobiol., *7*, 1936, 433.) Named for Prof. N. L. Söhngen who first studied this organism.

Rods: Straight to slightly bent, moderately long. Non-motile. Non-spore-forming. Gram-negative.

In liquid cultures cells are characteristically joined into long chains which often lie parallel to one another so as to form bundles.

Acetate and n-butyrate but not propionate are fermented with the production of methane and carbon dioxide.

Ethyl and n-butyl alcohols not fermented.

Obligate anaerobe.

Source: Enrichment cultures containing acetate or butyrate as the only organic compound. Four strains were isolated from acetate enrichment cultures. The cultures were highly purified but not strictly pure.

Habitat: Canal mud, sewage. Probably occurs widely in fresh water sediments where anaerobic conditions prevail.

2. **Methanobacterium omelianskii** Barker. (Bacille de la décomposition méthanique de l'alcohol ethylique, Omeliansky, Ann. Inst. Past., *30*, 1916, 80; Barker, Arch f. Mikrobiol., *7*, 1936, 436; also see Barker, Antonie van Leeuwenhoek, *6*, 1940, 201 and Jour. Biol. Chem., *137*, 1941, 153.) Named for Prof. W. Omeliansky who first observed the organism.

Rods: 0.6 to 0.7 by 1.5 to 10 microns, usual length 3 to 6 microns, unbranched, straight or slightly bent. Usually non-motile, occasionally feeble motility is observed. Spores of low heat resistance formed, spherical, terminal, swelling the rods.

Primary alcohols, including ethyl, propyl, n-butyl and n-amyl alcohols, are oxidized to the corresponding fatty acids. Secondary alcohols, including isopropyl and sec-butyl, are oxidized to the corresponding ketones. Hydrogen is oxidized.

Fatty and hydroxy acids, glucose, polyalcohols and amino acids are not attacked.

Carbon dioxide is used and converted to methane. Growth and alcohol oxidation are directly proportional to the carbon dioxide supply at low concentrations.

Nitrate, sulfate and oxygen cannot be used as oxidizing agents.

Utilizes ethyl alcohol best of all organic compounds.

Utilizes ammonia as a nitrogen source.

Growing range: pH 6.5 to 8.1.

Optimum temperature 37° to 40°C. Maximum 46° to 48°C.

Obligate anaerobe.

Source: Soil, fresh water and marine muds, rabbit feces, sewage. Pure cultures were isolated from fresh water and marine muds (Barker, *loc. cit.*, 1940).

Habitat: Wherever organic matter is decomposing in an anaerobic, approximately neutral environment.

Appendix III: Miscellaneous species of non-motile, or motile, non-spore-forming rod-shaped bacteria not previously listed or described.

Ascobacterium luteum Babes. (Babes, in Cornil and Babes, Les Bactéries, 3rd ed., *1*, 1890, 155; also see Petri, Cent. f. Bakt., II Abt., *26*, 1910, 359.) From water in Budapest (Babes) and the olive fly (Petri).

Bacillus a, b, c, d, e, f, h and *i*, Vignal. (Arch. d. phys. norm. et path., Sér. 3, *8*, 1886, 350–373; also see *Flavobacterium buccalis* Bergey et al. and *Bacillus buccalis fortuitus* Sternberg.) From saliva and the teeth.

Bacillus acido-aromaticus Van der Leck. (Cent. f. Bakt., II Abt., *17*, 1907, 652.) From milk.

Bacillus acutangulus Migula. (No. 13, Lembke, Arch. f. Hyg., *29*, 1897, 319; Migula, Syst. d. Bakt., *2*, 1900, 680.) From feces.

Bacillus acutus Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 433.) From the stomach of a bird.

Bacillus adametzii Migula. (Bacillus No. XIII, Adametz, Landwirtsch. Jahrb., *18*, 1889, 246; Migula, Syst. d. Bakt., *2*, 1900, 686; not *Bacillus adametzi* Trevisan, I generi e le specie delle Batteriacee, 1889, 19.) From cheese.

Bacillus aeris Chester. (*Bacillus violaceus sacchari* Ager, N. Y. Med. Jour., 1894, 265; see Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 369; *Bacterium violaceous sacchari* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 116; Chester, Man. Determ. Bact., 1901, 260.) From air. Produces a violaceus black pigment in old cultures in milk.

Bacillus aerobius Doyen. (*Bacillus urinae aerobius* Doyen, Jour. d. connaiss. médic., 1889, 107; Doyen, *ibid.*, 108.) From urine.

Bacillus aerogenes Miller. (Miller, Deutsche med. Wchnschr., *12*, 1886, 119; see Miller, Die Mikroorganismen der Mundhöhle, Leipzig, 1889, 262; not *Bacillus aerogenes* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 340.) From the stomach.

Bacillus aërogenes sputigenus capsulatus Herla. (Arch. de Biol., *14*, 1895, 403; abst. in Cent. f. Bakt., *25*, 1899, 359.) From the blood of a mouse which had been inoculated with the sputum of a pneumonia patient.

Bacillus aeschynomenus Trevisan. (Bacille de l'air *j*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 150; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From air.

Bacillus aëthebius Trevisan. (Bacille de l'air *c*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 149; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From air.

Bacillus agilis Trevisan. (Bacillus der Vagus-Pneumonie, Schou, Fortschr. d. Medicin, *3*, 1885, No. 15; *Bacillus pneumonicus agilis* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 262; Trevisan, I generi e le specie delle Batteriacee, 1889, 14; not *Bacillus agilis* Tschistowitsch, Berl. klin. Wochnschr., 1892, 512; not *Bacillus agilis* Chester, Man. Determ. Bact., 1901, 226; not *Bacillus agilis* Mattes, Sitzungsber. d. Gesells. z. Beforderung d. gesam. Naturw. z. Marburg, *62*, 1927, 406; not *Bacillus agilis* Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 33; *Bacterium pneumonicus agilis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 140; *Bacterium vagus pneumonie* Chester, *ibid.*, 144; *Bacillus pneumonicus* Migula, Syst. d. Bakt., *2*, 1900, 752.) From the lungs of rabbits having vagus pneumonia.

Bacillus agilis Mattes. (Sitzungsber. d. Gesells. z. Beforderung d. gesam. Naturw. z. Marburg, *62*, 1927, 406.) From the Mediterranean flour moth (*Ephestia kuehniella*).

Bacillus agillimus DeToni and Trevisan. (*Bacillus luteus putidus* Maggiora, Giorn. d. Soc. ital. d'Igiene, *11*, 1889, 344; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 969.) From the skin.

Bacillus agnorum Trevisan. (*Bacterium subtile agnorum* Rivolta, Giorn. di Anat. fisiol. degli animali, 1881, 31 and 1883, 78; Trevisan, I generi e le specie delle Batteriacee, 1889, 13.) From diseased lambs.

Bacillus alacer Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 13.) Found associated with the eggs of the nun moth (*Lymantria monacha*).

Bacillus alatus Grieg Smith. (Proc. Linn. Soc. New So. Wales, *30*, 1905, 570.)

Bacillus albatus Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 408.) From the stomach and intestines of a bird.

Bacillus albus Pagliani, Maggiora and Fratini. (Weisser Bacillus, Eisenberg, Bakt. Diag., 1 Aufl., 1886, Table 7; Pagliani et al., Giorn. d. Soc. ital. d'Igiene, *9*, 1887, 587; not *Bacillus albus* Trevisan, I generi e le specie delle Batteriacee, 1889, 14; not *Bacillus albus* Bergey et al., Manual, 3rd ed., 1930, 398; *Bacterium albus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 76.) From water.

Bacillus albus anaerobiescens Vaughan. (Amer. Jour. Med. Sci., *104*, 1892, 191.) From water.

Bacillus albus putidus DeBary. (Quoted from Sternberg, Man. of Bact., 1893, 675.) From water.

Bacillus albus-putidus Chester. (Maschek, see Adametz, Bakt. Nutz. u. Trinkwässer, 1888; Chester, Man. Determ. Bact., 1901, 237.) From water.

Bacillus albus putridus Vaughan. (Amer. Jour. Med. Sci., *104*, 1892, 186.) From water.

Bacillus alpha Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 366.) From air.

Bacillus amabilis Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 358; *Bacterium amabilis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 110.) From air.

Bacillus amarillae Trevisan. (Bacille de la fiévre jaune, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 529; Trevisan, I generi e le specie delle Batteriacee, 1889, 13.) From a case of yellow fever.

Bacillus amarus Migula. (*Bacillus liquefaciens lactis amari* v. Freudenreich, Landwirtsch. Jahrb. d. Schweiz, *8*, 1894; Migula, Syst. d. Bakt., *2*, 1900, 694; not *Bacillus amarus* Hammer, Iowa Agr. Exp. Sta. Res. Bull. 52, 1919, 198.) From bitter milk.

Bacillus amerimnus Trevisan. (Bacille de l'air *b*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 149; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From air.

Bacillus amygdaloides Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 246.) From brine on salted pickles.

Bacillus anceps Trevisan. (Bacille du mucus intestinal normal *a*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 153; Trevisan, I generi e le specie delle Batteriacee, 1889, 15.) From normal intestinal mucous.

Bacillus anthraciformis Wilhelmy. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 28.) From meat extract.

Bacillus anthracoides Trevisan. (Bacille de l'air *k*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 151; Trevisan, I generi e le specie delle Batteriacee, 1889, 20; not *Bacillus anthracoides* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 232.) From air.

Bacillus annulatus Zimmermann. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *2*, 1894, 30.) From water.

Bacillus anularius Henrici. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 32.) From Emmenthal cheese.

Bacillus apicum Kruse. (Canestrini, Atti Soc. Ven. Trent. Sci. Nat., *12*, 1892, 134; Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 233.) From infected bees and their larvae.

Bacillus apisepticus Burnside. (Jour. Econ. Ent., *21*, 1928, 379.) Pathogenic for the honey bee (*Apis mellifera*).

Bacillus aquatilis Migula. (*Bacillus*

aquatilis sulcatus IV, Weichselbaum, Das österreichische Sanitätswesen, 1889, No. 14–23; *Bacterium aquatilis sulcatus quartus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 72; Migula, Syst. d. Bakt., *2*, 1900, 733; not *Bacillus aquatilis* Frankland and Frankland, Ztschr. f. Hyg., *6*, 1889, 381; *Bacillus aquatilis-sulcatus-quartus* Chester, Man. Determ. Bact., 1901, 216.) From water.

Bacillus aquatilis Trevisan. (Bacille de l'eau *a*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 167; Trevisan, I generi e le specie delle Batteriacee, 1889, 19; not *Bacillus aquatilis* Frankland and Frankland, Ztschr. f. Hyg., *6*, 1889, 381.) From water.

Bacillus aquatilis communis Kruse. (Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 315; *Bacterium aquatilis communis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 91.) Found commonly in water. Listed by Kruse as a non-chromogenic strain of *Bacillus fluorescens liquefaciens* (*Pseudomonas fluorescens* Migula).

Bacillus arborescens Jamieson and Edington. (Brit. Med. Jour., *1*, 1887, 1265.) From the desquamation of scarlet fever patients.

Bacillus arboreus Migula. (Bäumchenbacillus, Maschek, Bakt. Untersuch. d. Leitmeritzer Trinkwässer, Leitmeritz, 1887; Migula, Syst. d. Bakt., *2*, 1900, 710.) From water.

Bacillus aromaticus Beijerinck. (Quoted from Van der Leck, Cent. f. Bakt., II Abt., *17*, 1907, 490; not *Bacillus aromaticus* Pammel, Bull. 20, Iowa Agr. Exp. Sta., 1893, 792; not *Bacillus aromaticus* Grimm, Cent. f. Bakt., II Abt., *8*, 1902, 589; not *Bacillus aromaticus* Van der Leck, *loc. cit.*, 659.) From milk.

Bacillus aromaticus Van der Leck. (Van der Leck, Cent. f. Bakt., II Abt., *17*, 1907, 659.) From soft cheeses.

Bacillus assimilis Trevisan. (Bacille de l'air *i*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 150; Trevisan, I generi e le specie delle Batteriacee, 1899, 20.) From air.

Bacillus aurantius Trevisan. (Orangerother Wasserbacillus, Adametz and Wichmann, Mitth. Oest. Vers. Stat. f. Brauerei u. Mälz. in Wien, *1*, 1888, 50; Trevisan, I generi e le specie delle Batteriacee, 1889, 19; not *Bacillus aurantius* Bergey et al., Manual, 3rd ed., 1930, 421.) From water.

Bacillus aureus Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 9; probably not *Bacillus aureus* Frankland and Frankland, Philos. Trans. Roy. Soc. London, *178*, B, 1887, 272 and probably not *Bacillus aureus* Pansini, Arch. f. path. Anat. u. Physiol., *122*, 1890, 436; not *Bacillus aureus* Adametz, quoted from Sternberg, Man. of Bact., 1893, 621.) Capable of infecting the larvae of various insects.

Bacillus azureus Zimmermann. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *2*, 1894, 24.) From water.

Bacillus babesi Trevisan. (Bacille du mucus intestinal normal *b*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 153; Trevisan, I generi e le specie delle Batteriacee, 1889, 15.) From normal intestinal mucus.

Bacillus belfantii Migula. (Eine neue pathogene Bakteriumart im Tetanusmaterial, Belfanti and Pescarolo, Cent. f. Bakt., *4*, 1888, 513; *Bacillus accidentalis tetani* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 433; *Bacterium accidentalis tetani* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 88; Migula, Syst. d. Bakt., *2*, 1900, 767; not *Bacillus belfanti* Carbone and Venturelli, Boll. Ist. Sieroter., Milan, *4*, 1925, 59; *Bacillus accidentalis* Chester, Man. Determ. Bact., 1901, 229.) From pus in a case of tetanus.

Bacillus benzoli Tausson. (Planta, *7*, 1929, 735.) From soil. Oxidizes benzene.

Bacillus beribericus Trevisan. (Caratt. di alc. nuov. gen. di Batt., 1885, 12.) From cases of beri-beri in Japan.

Also see Ogata, abst. in Cent. f. Bakt., *3*, 1888, 75.

Bacillus berolinensis Migula. (Roter Bacillus aus Wasser, Fraenkel, Grundriss der Bakterienkunde, 3 Aufl., 1890, 252; *Bacillus ruber berolinensis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 303; *Bacterium ruber berolinensis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 113; Migula, Syst. d. Bakt., *2*, 1900, 856; not *Bacillus berolinensis* Chester, Man. Determ. Bact., 1901, 305.) From water. Rust-red to orange-yellow pigment on potato.

Bacillus beta Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 366.) From air.

Bacillus beyerinckii DeToni and Trevisan. (*Bacillus radicicola* var. *liquefaciens* Beijerinck, Bot. Zeitung, 1888, 750; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 972; not *Bacillus beijerinckii* Henneberg, Ztschr. f. Spiritusindustrie, *26*, 1903, 22; see Cent. f. Bakt., II Abt., *11*, 1903, 159.) From soil and the roots of legumes.

Bacillus billingsi Chester. (Bacillus of corn-stalk disease of cattle, Billings, in Baumgarten, Jahresbericht, 1889, 184; Chester, Man. Determ. Bact., 1901, 214.) Isolated by Billings from corn-stalk disease of cattle, and by Nocard from bronchopneumonia in oxen.

Bacillus bombycis Chatton. (Chatton, Compt. rend. Acad. Sci., Paris, *156*, 1913, 1708; not *Bacillus bombycis* Macchiati, Stazioni sperimentali Agrarie Italiane, *20*, 1891, 121; *Bacterium bombycis* Paillot, L'infection chez les insectes, 1933, 131.) From diseased silkworms (*Bombyx mori*).

Bacillus bookeri Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 378; not *Bacillus bookeri* Ford, Studies from the Royal Victoria Hospital, Montreal, *1*, 1903, 31.) Found by Dr. Prudden in a case of cystitis.

Bacillus brachythrix DeToni and Trevisan. (*Bacillus G*, Maggiora, Giorn. Soc. ital. d'Igiene, *11*, 1889, 348; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 967.) From the skin.

Bacillus brunneus (Schroeter) Schroeter. (*Bacteridium brunneum* Schroeter, in Cohn, Beitr. z. Biol. d. Pflanz., *1*, Heft 2, 1872, 126; Schroeter, in Cohn, Kryptog. Flora v. Schlesien, *3* (1), 1886, 158; not *Bacillus brunneus* Adametz and Wichmann, Die Bakt. der Nutz- und Trinkwässer, Wien, 1888; *Bacillus fuscus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 290; not *Bacillus fuscus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 70.) *Bacterium brunneum* Schroeter or Cohn is given as a synonym by Flügge (1886) and by Trevisan (1889) but this appears to be an incorrect spelling of *Bacteridium brunneum* Schroeter. Neither Schroeter nor Cohn used *Bacterium brunneum* in 1872 or later so far as can be determined by a careful study of their papers. From corn, wheat and potato infusions.

Bacillus buccalis fortuitus Sternberg. (Bacillus j, Vignal, Arch. Phys. norm. et path., Sér. 3, *8*, 1886, 337; Sternberg, Man. of Bact., 1893, 685; *Bacterium bucalis* (sic) *fortuitus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 91 and 130; *Bacillus bucalis* (sic) Chester, Man. Determ. Bact., 1901, 234; not *Bacillus buccalis* Trevisan, I generi e le specie delle Batteriacee, 1889, 15.) From the mouth.

Bacillus buccalis muciferens Miller. (Miller, Dental Cosmos, *33*, 1891, 792 and 800.) From the blood. A slimy capsulated bacillus.

Bacillus buccalis septicus Miller. (Miller, Dental Cosmos, *33*, 1891, 792 and 802.) From the mouth and in pus of an abscess caused by a dental instrument.

Bacillus butyri Migula. (*Bacillus butyri I*, v. Klecki, Cent. f. Bakt., *15*, 1894, 357; Migula, Syst. d. Bakt., *2*, 1900, v and 811.) From rancid butter.

Bacillus caeci Ford. (Studies from the Royal Victoria Hosp., Montreal, *1*, (5), 1903, 45; also see Jour. Med. Res.,

1, 1901, 217.) From the stomach and rectum.

Bacillus canalensis Castellani. (Proc. Soc. Exp. Biol. and Med., *25*, 1928, 540.) From human feces.

Bacillus canus Migula. (Grauer Bacillus, Maschek, Untersuch. d. Leitmeritzer Trinkwässer, Leitmeritz, 1887; Migula, Syst. d. Bakt., *2*, 1900, 711.) From water.

Bacillus canus Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *24*, 1894, 15.) From larvae of the nun moth (*Lymantria monacha*.)

Bacillus carabiformis Raczyscki. (Diss. milit. medic. Acad. Petropolitanae Ruteniae, 1888; abst. in Cent. f. Bakt., *6*, 1889, 113.) From the stomach of a dog.

Bacillus carnis Wilhelmy. (Wilhelmy, Arb. bakt. Inst. Karlsruhe, *3*, 1903, 21; not *Bacillus carnis* Klein, Cent. f. Bakt., II Abt., *35*, 1903, 459.) From meat extract.

Bacillus caseolyticus Lochmann. (Cent. f. Bakt., I Abt., Orig., *31*, 1902, 385.) From the organs of guinea pigs which had been inoculated with tubercle bacilli.

Bacillus cathetus Trevisan. (Bacille de l'air *g*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 150; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From air.

Bacillus caviae Trevisan. (Bacille du mucus intestinal normal du cobaye *e*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 154; Trevisan, I generi e le specie delle Batteriacee, 1889, 15; *Pasteurella caviae* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 996; not *Pasteurella caviae* Hauduroy et al., Dict. d. Bact. Path., 1937, 313.) From the intestinal mucus of guinea pigs.

Bacillus centralis Zimmermann. (Bakt. unserer Trink. u. Nutzwässer, Chemnitz, *2*, 1894, 10.) From water.

Bacillus charrini Trevisan. (Bacille de la pseudo-tuberculose bacillaire du cobaye, Charrin and Roger, Compt. rend. Acad. Sci., Paris, *106*, 1888, 868; Trevisan, I generi e le specie delle Batteriacee, 1889, 13.) From pulmonary tuberculosis of guinea pigs.

Bacillus chlorinus Migula. (Grüngelber Bacillus, Tataroff, Inaug. Diss., Dorpat, 1891, 50; Migula, Syst. d. Bakt., *2*, 1900, 820; not *Bacillus chlorinus* Frankland and Frankland, Philos. Trans. Roy. Soc. London, *178*, B, 1887, 274.) From water.

Bacillus chyluriae Trevisan. (Bacillus of chyluria, Wilson, Brit. Med. Jour., No. 1249, 1884, 1128; Trevisan, Atti Acad. Med.-Fis.-Stat. Milan., Ser. V, *3*, 1885, 99.) From chyluria.

Bacillus citreus (Unna and Tommasoli) Kruse. (*Ascobacillus citreus* Unna and Tommasoli, Monats. f. prakt. Dermatol., *9*, 1890, 60; Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 309; not *Bacillus citreus* Frankland and Frankland, Philos. Trans. Roy. Soc., London, *178*, 1887, B, 272; *Bacterium citreus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 104.) From the human skin in cases of eczema.

Bacillus citricus Kern. (Kern, Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 426; not *Bacillus citricus* Weiss, *ibid.*, *2*, Heft 2, 1902, 234.) From the intestines of birds.

Bacillus citrinus Migula. (Citrongelber Bacillus, Maschek, Bakt. Untersuch. d. Leitmeritzer Trinkwässer, 1887; Migula, Syst. d. Bakt., *2*, 1900, 832.) From water.

Bacillus cladogenes Trevisan. (Bactérie de l'air No. 3, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 140; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From air.

Bacillus claviformis Doyen. (*Bacillus urinae claviformis* Doyen, Jour. d. connaiss. médic., 1889, 106; Doyen, *ibid.*, 108; *Bacillus doyeni* DeToni and Trevi-

san, in Saccardo, Sylloge Fungorum, *8*, 1889, 949.) From urine.

Bacillus cleoni Picard. (Bull. Soc. d'Étude et de Vulgarisation Zool. Agric., *12*, 1913, 134.) A fluorescent coccobacillus. From diseased larvae of weevils (*Temnorrhinus* (*Cleonus*) *mendicus*).

Bacillus coccineus Catiano. (Catiano, in Cohn, Beitr. z. Biol. d. Pflanz., *7*, 1896, 339; not *Bacillus coccineus* Pansini, Arch. f. path. Anat., *122*, 1890, 437; *Bacillus subcoccineus* Migula, Syst. d. Bakt., *2*, 1900, 857.) From the vagina. Reddish pigment.

Bacillus coeruleo-viridis Trevisan. (Blaugrün fluorescirende Bacterium, Adametz, Mitth. Oest. Vers. Stat. f. Brauerei u. Mälz. in Wien, *1*, 1888, 46; Trevisan, I generi e le specie delle Batteriacee, 1889, 20; *Bacterium coeruleoviride* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1087.) From water.

Bacillus coeruleus Eckstein. (Eckstein, Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 14; not *Bacillus coeruleus* Smith, Med. News, 1887, 758; probably not *Bacillus coeruleus* Voges, Cent. f. Bakt., *14*, 1893, 301.) From larvae of the nun moth (*Lymantria monacha*).

Bacillus columbarum Chester. (Bacillus of pigeon cholera, Moore, U.S. D.A., Bur. Anim. Ind., Bull. 8, 1895; Chester, Man. Determ. Bact., 1901, 209.) From a disease of pigeons. Hadley et al. (Rhode Island Agr. Exp. Sta., Bull. 174, 1918, 178) regard this as probably a paracolon.

Bacillus constrictus Zimmermann. (Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 42; *Bacterium constrictus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 112.) From water.

Bacillus convolutus Wright. (Wright, Mem. Nat. Acad. Sci., *7*, 1895, 461; *Bacterium convolutus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 101.) From river water.

Bacillus coprogenes foetidus Sternberg. (Darmbacillus, Schottelius, 1885; Sternberg, Man. of Bact., 1893, 468.) From the intestinal contents of pigs which had died of swine erysipelas.

Bacillus coronatus Keck. (Inaug. Diss., Dorpat, 1890, 43.) From water.

Bacillus corvi Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 394.) From the stomach and intestines of birds.

Bacillus courmontii Migula. (Courmont, Compt. rend. Soc. Biol., Paris, 1889; *Bacillus pseudotuberculosis similis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 454; Migula, Syst. d. Bakt., *2*, 1900, 770.) From tubercles of cattle.

Bacillus crassus Lucet. (*Bacillus crassus pyogenes bovis* Lucet, Ann. Inst. Past., *7*, 1897, 327; *Bacillus crassus pyogenes* Lucet, *ibid.*, 327; Lucet, *ibid.*, 328; *Bacillus pyogenes crassus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 343; *Bacterium pyogenes crassus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 141; *Bacillus bovis* Migula, Syst. d. Bakt., *2*, 1900, 765.) From bovine abscesses. Regarded by Kruse as a synonym of *Bacillus pneumoniae*.

Bacillus crinitus Migula. (No. 15, Lembke, Arch. f. Hyg., *29*, 1897, 321; Migula, Syst. d. Bakt., *2*, 1900, 678.) From feces.

Bacillus cubonianus Cuboni and Garbini. (Atti. dei Lincei, Ser. 4, *6*, 1890, 26–27, quoted from Steinhaus, Bact. Assoc. Extracell. with Insects and Ticks, Minneapolis, 1942, 53; not *Bacillus cubonianus* Macchiati, Staz. Sperim. Agr. Ital., *23*, 1892, 228.) From silkworms (*Bombyx mori*).

Bacillus cuenoti Mercier. (Bakterienähnlichen Gebilden, Blochmann, Ztschr. f. Biol., *24*, 1887, 1; Compt. rend. Soc. Biol., Paris, *61*, 1906, 682; also in Arch. f. Protistenkunde, *9*, 1907, 346.) From the fat body of the cockroach (*Periplaneta orientalis*).

Bacillus cuniculi Migula. (*Bacillus septicus cuniculi* Lucet, Ann. Inst. Past., *6*, 1892, 564; *Bacillus cuniculi septicus* Kruse, in Flügge, Die Mikroorganismen,

3 Aufl., *2*, 1896, 406; *Bacterium cuniculi septicus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 76; Migula, Syst. d. Bakt., *2*, 1900, 758.) Associated with a spontaneous epizootic of rabbits.

Bacillus cuniculicida immobilis Kruse. (Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 417; *Bacterium cuniculicida immobilis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 84; *Bacterium cuniculicida* var. *immobile* Chester, Man. Determ. Bact., 1901, 140.) Cause of a disease of rabbits.

Bacillus cystiformis Clado. (Quoted from Sternberg, Man. of Bact., 1893, 649). From urine in a case of cystitis.

Bacillus cystitidis Migula. (*Coccobacillus aerogenes vesicae* Schow, Cent. f. Bakt., *12*, 1892, 749; *Bacillus aerogenes vesicae* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 237; *Bacterium aerogenes vesicae* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 128; Migula, Syst. d. Bakt., *2*, 1900, 771; *Bacillus aerogenes* Chester, Man. Determ. Bact., 1901, 227; not *Bacillus aerogenes* Miller, Deutsche med. Wochnschr., *12*, 1886, 119; not *Bacillus aerogenes* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 340.) From urine in a case of cystitis.

Bacillus dacryoideus Migula. (*Bacillus oogenes hydrosulfureus* η, Zörkendörfer, Arch. f. Hyg., *16*, 1893, 389; Migula, Syst. d. Bakt., *2*, 1900, 791.) From hens' eggs.

Bacillus decolor Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 15.) From the larvae of a butterfly (*Vanessa utricae*).

Bacillus decolorans major Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 362.) From air.

Bacillus decolorans minor Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 359.) From air.

Bacillus defessus Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 397.) From the stomach and intestines of birds.

Bacillus delta Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 368; *Bacterium delta* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 114.) From water.

Bacillus denitrificans Giltay and Aberson. (Giltay and Aberson, Arch. Néerl. Sci. exact. et nat., *25*, 1891, 341; quoted from Sternberg, Man. of Bact., 1893, 727; not *Bacillus denitrificans* Migula, Syst. d. Bakt., *2*, 1900, 796; not *Bacillus denitrificans* Chester, Man. Determ. Bact., 1901, 274.) From soil and air.

Bacillus denitrofluorescens van Iterson. (Cent. f. Bakt., II Abt., *9*, 1902, 772; *12*, 1904, 111.) Fluorescent. From soil.

Bacillus dentalis viridans Miller. (Miller, Die Mikroorganismen der Mundhöhle, Leipzig, 1889, 218.) From carious teeth.

Bacillus dermoides Tataroff. (Inaug. Diss., Dorpat, 1891, 19.) From water.

Bacillus diaphanus Migula. (*Halibacterium pellucidum* Fischer, Die Bakterien des Meeres, 1894, 22; Migula, Syst. d. Bakt., *2*, 1900, 712.) From sea water.

Bacillus diffluens Doyen. (*Bacillus urinae diffluens* Doyen, Jour. d. connaiss. médic., 1889, 107; Doyen, *ibid.*, 108; not *Bacillus diffluens* Castellani, 1915, see Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 943.) From urine.

Bacillus digitatus Migula. (Bacillus No. 7, Pansini, Arch. f. path. Anat., *122*, 1890, 443; Migula, Syst. d. Bakt., *2*, 1900, 659.) From sputum.

Bacillus dissimilis Trevisan. (Bacillus I, Leube, Arch. f. path. Anat., *100*, 1885, 556; Trevisan, I generi e le specie delle Batteriacee, 1889, 16.) From urine.

Bacillus domesticus Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 358; *Bacterium domesticus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 110.) From air.

Bacillus droserae (Troili-Petersson) Buchanan and Hammer. (*Bacterium droserae* Troili-Petersson, Cent. f. Bakt., II Abt., *38*, 1913, 1; Buchanan and Hammer, Iowa Sta. Coll. Agr. Exp. Sta., Res. Bull. 22, 1915, 256.) Isolated by placing leaves of a sundew (*Drosera intermedia*) in milk and isolating the

slimy milk organisms developing. Closely related to *Bacterium lacto-rubefaciens* Gruber, according to Buchanan and Hammer.

Bacillus duclauxii (Miquel) DeToni and Trevisan. (*Urobacillus duclauxii* Miquel, Ann. d. Microgr., *2*, 1889, 58; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 963.) From sewage.

Bacillus eczemicus Trevisan. (I generi e le specie delle Batteriacee, 1889, 14.) From exudate in cases of eczema.

Bacillus egregius Zopf. (Quoted from Papenhausen, Arb. bakt. Inst. Karlsruhe, *3*, 1903, 59.) A reddish-yellow non-spore-forming rod.

Bacillus elipsoideus Migula. (*Bacillus saprogenes vini* v, Kramer, Die Bakterien in ihren Beziehungen zur Landwirtschaft, *2*, 1892, 138; Migula, Syst. d. Bakt., *2*, 1900, 684.) From wine.

Bacillus ellingtonii Chester. (Bacillus No. 21, Conn, Rept. Conn. (Storrs) Agr. Exp. Sta., 1893, 52; Chester, Man. Determ. Bact., 1901, 264.) From milk.

Bacillus eminans Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 232.) From vegetable infusions.

Bacillus emulsinus Fermi and Montesano. (Cent. f. Bakt., *15*, 1894, 722.) From air. Decomposes amygdalin.

Bacillus endocarditidis Migula. (*Bacillus endocarditidis griseus* Weichselbaum, Beitr. z. path. Anat., *4*, 1889, 119; *Bacterium endocarditidis griseus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 88; Migula, Syst. d. Bakt., *2*, 1900, 750.) From a case of endocarditis.

Bacillus engelmanni Trevisan. (*Bacterium chlorinum* Engelmann, see Flügge, Die Mikroorganismen, 2 Aufl., 1886, 289; not *Bacterium chlorinum* Migula, Syst. d. Bakt., *2*, 1900, 471; Trevisan, I generi e le specie delle Batteriacee, 1889, 18.) Source not given.

Bacillus enteromyces Trevisan. (Bacille des selles *f*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 154; Trevisan, I generi e le specie delle Batteriacee, 1889, 15.) From feces.

Bacillus entomotoxicon Duggar. (Bull. Illinois State Lab. Nat. Hist., *4*, 1896, 340–379.) From the squash bug (*Anasa tristis*).

Bacillus epsilon Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 369; *Bacterium epsilon* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 114.) From air.

Bacillus equi Migula. (*Bacillus equi intestinalis* Dyar and Keith, Technol. Quarterly, *6*, 1893, No. 3; abst. in Cent. f. Bakt., *16*, 1894, 838; *Bacterium equi intestinalis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 70; Migula, Syst. d. Bakt., *2*, 1900, 874; *Bacillus intestinalis* Chester, Man. Determ. Bact., 1901, 213.) From the intestines of a horse.

Bacillus erubescens Migula. (*Bacillus oogenes hydrosulfureus* κ, Zörkendörfer, Arch. f. Hyg., *16*, 1893, 391; Migula, Syst. d. Bakt., *2*, 1900, 792; *Bacillus rubescens* Nepveux, Thèse, Fac. Pharm. Paris, 1920, 113.) From hens' eggs.

Bacillus erythrogenes rugatus Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 374.) A wrinkled variety of *Bacillus lactis erythrogenes* Hueppe.

Bacillus erythrosporus Miflet. (Miflet, in Cohn, Beitr. z. Biol. d. Pflanz., *3*, Heft 1, 1879, 135; *Bacillus* (*Streptobacter*) *erythrospores* (sic) Schroeter, in Cohn, Krypt. Flora v. Schles., *3*, 1, 1886, 158; *Bacterium erythrosporus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 123.) From putrefying egg-white and meat infusion. According to Chester, the author mistook reddish granules for spores. Fluorescent.

Bacillus esterificans fluorescens Maassen. (Arb. a. d. k. Gesundsheitsamte, *15*, 1899, 504–507.) From grains and from rotting vegetation in river water.

Bacterium esterificans stralauense Maassen. (Arb. a. d. k. Gesundheitsamte, *15*, 1899, 504–507.) From Spree River water.

Bacillus eta Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 374; *Bacterium eta* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 107.) From air.

Bacillus ethaceticus Frankland and

Frankland. (Proc. Roy. Soc. London, *46*, 1889.) Ferments mannitol, glycerol and glucose to ethyl alcohol and acetic acid with a trace of formic and succinic acids.

Bacillus ethacetosuccinicus Frankland and Frew. (Transactions of the Chemical Society, 1892, 275.) Ferments mannitol and dulcitol to ethyl alcohol, acetic acid, succinic acid, hydrogen and carbonic acid.

Bacillus exapatus Trevisan. (Bacillus der conjunctivalsack *f*, Fick, Ueber Mikroorg. in Conjunctivalsack, Wiesbaden, 1887; Trevisan, I generi e le specie delle Batteriacee, 1889, 15.) Found frequently in the human eye.

Bacillus exiguus Wright. (Wright, Mem. Nat. Acad. Sci., *7*, 1895, 447; *Bacterium exiguum* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 114; not *Bacterium exiguum* Stäubli, Münchner med. Wochnschr., No. 45, 1905.) From water.

Bacillus famiger Trevisan. (Bacillus bei Erysipel am Kaninchenohr, Flügge, Die Mikroorganismen, 2 Aufl., 1886, 283; Trevisan, I generi e le specie delle Batteriacee, 1889, 14.) From a case of erysipelas of the ear of a rabbit.

Bacillus felis (Rivolta) Trevisan. (*Cocco-bacterium felis* Rivolta, Giorn. di Anatomia, No. 1, 1888; Trevisan, I generi e le specie delle Batteriacee, 1889, 14.) From an infection in a cat.

Bacillus fermentationis Chester. (*Bacillus foetidus liquefaciens* Tavel, Ueber d. Actiol. d. Strumitis, Basel, 1892; Chester, Man. Determ. Bact., 1901, 233.) From strumitis.

Bacillus ferrugineus Rullmann. (Rullmann, Cent. f. Bakt., I Abt., *24*, 1898, 467; not *Bacillus ferrugineus* Van Iterson, Cent. f. Bakt., II Abt., *11*, 1903, 694.) From canal water.

Bacillus ferrugineus Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 361; not *Bacillus ferrugineus* Rullmann, Cent. f. Bakt., I Abt., Orig., *24*, 1898, 465; *Bacterium furrugineus* (sic) Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 115; *Bacterium ferrugineum* Chester, Man. Determ. Bact., 1901, 177.) From air and from a fresh leaf of the pitcher plant (*Sarracenia purpurea*).

Bacillus fertilis DeToni and Trevisan. (*Bacillus urinae fertilis* Doyen, Jour. d. connaiss. médic., 1889, 107; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 949.) From urine.

Bacillus figurans Vaughan. (Vaughan, Amer. Jour. Med. Sci., *104*, 1892, 107; not *Bacillus figurans* Crookshank, Man. of Bact., 1st ed., 1886.) From water.

Bacillus finitimus ruber Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 361.) From air.

Bacillus flavidescens Migula. (*Bacillus aquatilis sulcatus* v, Weichselbaum, Das österreichische Sanitätswesen, 1889, No. 14–23; *Bacillus aquatilis sulcatus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 382; Migula, Syst. d. Bakt., *2*, 1900, 734; *Bacillus weichselbaumii* Chester, Man. Determ. Bact., 1901, 218.) From water.

Bacillus flavoides Castellani. (Proc. Soc. Exp. Biol. and Med., *25*, 1928, 539.) From the human skin.

Bacillus flavus Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 12; not *Bacillus flavus* Fuhrmann, Cent. f. Bakt., II Abt., *19*, 1907, 117; not *Bacillus flavus* Bergey et al., Manual, 1st ed., 1923, 286.) From dead larvae of a butterfly (*Vanessa polychlorus*).

Bacillus flexuosus Wright. (Wright, Mem. Nat. Acad. Sci., *7*, 1895, 460; *Bacterium flexuosus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 100.) From river water.

Bacillus floccosus Kern. (Kern, Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 424; not *Bacillus floccosus* Weinberg et al., Les Microbes Anaérobies, 1937, 698.) From the stomach and intestines of birds.

Bacillus fluidificans DeToni and Trevisan. (*Bacillus fluidificans parvus* Maggiora, Giorn. Soc. ital. d'Igiene, *11*, 1889, 344; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 969.) From the skin.

Bacillus fluorescens Chester. (*Bacillus fluorescens aureus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 14; *Bacterium fluorescens aureus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 109; Chester, Man. Determ. Bact., 1901, 255; not *Bacillus fluorescens* Trevisan, I generi e le specie delle Batteriacee, 1889, 19; not *Bacillus fluorescens* Bergey et al., Manual, 1st ed., 1923, 287.) From water.

Bacillus fluorescens Pagliani, Maggiora and Fratini. (Pagliani et al., Giorn. d. Soc. ital. d'Igiene, *9*, 1887, 587; not *Bacillus fluorescens* Bergey et al., Manual, 1st ed., 1923, 287; *Bacillus paglianii* Trevisan, I generi e le specie delle Batteriacee, 1889, 19; not *Bacillus paglianii* Carbone and Venturelli, Boll. Ist. Sieroter., Milan, *4*, 1925, 59.) From water and soil.

Bacillus fluorescens albus Zimmermann. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 18.) From water.

Bacillus fluorescens baregensis Robine and Hauduroy. (Compt. rend. Soc. Biol. Paris, *98*, 1928, 25.) From the water of hot sulfur springs. Fourment (Compt. rend. Soc. Biol. Paris, *98*, 1928, 588) states that this organism is a variety of *Bacillus fluorescens liquefaciens* Kruse, but Robine and Hauduroy (Compt. rend. Soc. Biol. Paris, *99*, 1928, 317) deny this.

Bacillus fluorescens liquefaciens minutissimus Unna and Tommasoli. (Quoted from Sternberg, Man. of Bact., 1893, 636.) From the surface of the body in cases of eczema seborrhoeicum.

Bacillus fluorescens longus Zimmermann. (Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 20; *Bacterium fluorescens longus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 124.) From water.

Bacillus fluorescens tenuis Zimmermann. (Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 14; *Bacterium fluorescens tenuis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 124.) From water.

Bacillus foetidus Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 12.) From dead larvae of a butterfly (*Vanessa urticae*).

Bacillus foetidissimus Migula. (*Bacillus pyogenes foetidus liquefaciens* Lanz, Cent. f. Bakt., *14*, 1893, 269; *Bacterium pyogenes foetidus liquefaciens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 92; Migula, Syst. d. Bakt., *2*, 1900, 643.) From a brain abscess.

Bacillus fortissimus Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 209.) From asparagus and brewer's grain infusions.

Bacillus fuliginosus Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 224.) From vegetable infusions.

Bacillus fulvus Edington. (Edington, Brit. Med. Jour., June 11, 1887, 1262; not *Bacillus fulvus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 44; not *Bacillus fulvus* Migula, Syst. d. Bakt., *2*, 1900, 844.) Associated with cases of scarlatina. Not pathogenic.

Bacillus fulvus Migula. (*Bacillus tuberigenus 4*, Gonnermann, Landwirtsch. Jahrb., *23*, 1894, 656; Migula, Syst. d. Bakt., *2*, 1900, 844; not *Bacillus fulvus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 44.) From root nodules on lupine.

Bacillus fumeus Migula. (No. 5, Lembke, Arch. f. Hyg., *29*, 1897, 313; Migula, Syst. d. Bakt., *2*, 1900, 787.) From feces.

Bacillus fumosus Migula. (No. 4, Lembke, Arch. f. Hyg., *29*, 1897, 312; Migula, Syst. d. Bakt., *2*, 1900, 788.) From feces.

Bacillus fungosus Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 255.) From fermenting beets.

Bacillus fuscans Miller. (Miller, Die Mikroorganismen der Mundhöhle, Leipzig, 1889, 70.) From the mouth.

Bacillus fuscescens Migula. (*Bacillus fuscus limbatus* Scheibenzuber, Allgem. Wiener med. Zeitung, *34*, 1889, 171;

Bacterium fuscus limbatus Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 117; Migula, Syst. d. Bakt., *2*, 1900, 836; *Bacterium fuscescens* Chester, Man. Determ. Bact., 1901, 179; *Bacillus fuscus* Chester, *ibid.*, 261; not *Bacillus fuscus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 290; not *Bacillus fuscus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 70.) From rotten eggs.

Bacillus galtieri Trevisan. (Microbe pathogène chromo-aromatique du porc, Galtier, Compt. rend. Acad. Sci. Paris, *106*, 1888, 1368; Trevisan, I generi e le specie delle Batteriacee, 1889, 14; *Bacillus chromoaromaticus* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 360; *Bacterium chromo-aromaticus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 119; *Bacillus helvolus* Chester, Man. Determ. Bact., 1901, 264; not *Bacillus helvolus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 52.) From lesions in a case of broncho-pneumonia in hogs.

Bacillus gasoformans Pribram. (*Bacterium aquatile gasoformans non liquefaciens* von Rigler, Hyg. Rund., *12*, 1902, 482; *Bacterium gasoformans non liquefaciens* von Rigler, *ibid.*, 485 and Cent. f. Bakt., I Abt., Ref., *31*, 1902, 682; *Bacillus aquatilis gasoformans non liquefaciens* Pribram, Klassification der Schizomyceten, Leipzig und Wien, 1933, 83; *ibid.*, 83.) From bottled mineral waters. Similar to coliform bacteria except that it is a yellow chromogen.

Bacillus gaytoni Cheshire. (Bees and Bee Keeping, London, *2*, Part 13, 1886, 543 and 569.) Found in black bees (*Apis mellifera*), i.e., black because of the loss of hairy covering.

Bacillus gelatinosus Migula. (*Bacterium gelatinosum betae* Glaser, Cent. f. Bakt., II Abt., *1*, 1895, 879; Migula, Syst. d. Bakt., *2*, 1900, 805.) From beet juice.

Bacillus gelatogenes Black. (Trans. Ill. State Dental Soc., *22*, 1886, 187.) From the mouth.

Bacillus geton Trevisan. (Bacille de l'eau *b*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 168; Trevisan, I generi e le specie delle Batteriacee, 1889, 19.) From water.

Bacillus gigas Goot. (Goot, Med. Proefstat. voor de Java Suikerindustrie, Pt. 5, No. 10, 60 pp., quoted from Steinhaus, Bact. Assoc. Extracell. with Insects and Ticks, Minneapolis, 1942, 58; not *Bacillus gigas* Zeissler and Rassefeld, Arch. f. wiss. u. prakt. Tierheilk., *59*, 1929, 419.) From larval and adult stages of a beetle (*Adoretus compressus*).

Bacillus (?) *gingivae* Migula. (*Bacterium gingivae pyogenes* Miller, Die Mikroorganismen der Mundhöhle, Leipzig, 1889, 217; *Bacillus pyogenes gingivae* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 287; Migula, Syst. d. Bakt., *2*, 1900, 642.) From the oral cavity.

Bacillus glaucus Maschek. (Maschek, Bakt. Untersuch. d. Leitmeritz. Trinkwässer, Jahresber. d. Oberrealschule zu Leitmeritz, 1887; quoted from Sternberg, Man. of Bact., 1893, 637; *Bacterium glaucus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 116.) From water.

Bacillus globosus Migula. (*Bacterium A*, Peters, Botan. Zeit., *47*, 1889; Migula, Syst. d. Bakt., *2*, 1900, 798.) From fermenting dough.

Bacillus globulosus Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 253.) From sauerkraut and bean infusions.

Bacillus gonnermanni Migula. (*Bacillus tuberigenus II*, Gonnermann, Landwirtsch. Jahrb., *23*, 1894, 656; Migula, Syst. d. Bakt., *2*, 1900, 682.) From root nodules on a lupine.

Bacillus gortynae Paillot. (Compt. rend. Acad. Sci., Paris, *157*, 1913, 611.) From caterpillars of *Gortyna ochracea*. A coccobacillus.

Bacillus gracilescens Henrici. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 26.) From Swiss cheese.

Bacillus gracilis Kern. (Kern, Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 421; not *Bacillus gracilis* Zimmermann,

Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 50; *Bacillus gracilior* Migula, Syst. d. Bakt., *2*, 1900, 664.) From the stomach and intestines of birds.

Bacillus gracilis aerobiens Vaughan. (Amer. Jour. Med. Sci., *104*, 1892, 187.) From water.

Bacillus gracilis anaerobiescens Vaughan. (Amer. Jour. Med. Sci., *104*, 1892, 187.) From water.

Bacillus gracilis cadaveris Sternberg. (Sternberg, Man. of Bact., 1893, 733; *Bacterium gracilis cadveris* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 84.) From the human liver.

Bacillus grandis Trevisan. (Bacille de l'air *h*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 150; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From air.

Bacillus granulatus Chester. (*Bacillus aquatilis solidus* Lustig, Diag. Bakt. d. Wassers, 1893; *Bacterium aquatilis solidus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 76; Chester, Man. Determ. Bact., 1901, 223.) From water.

Bacillus granulosus Losski. (Losski, Inaug. Diss., Dorpat, 1893, 25; not *Bacillus granulosus* Russell, Ztschr. f. Hyg., *11*, 1892, 99; not *Bacillus granulosus* Gerstner, Arb. bakt. Inst. Karlsruhe, *1*, Heft 2, 1894, 167; *Bacillus subgranulosus* Migula, Syst. d. Bakt., *2*, 1900, 820.) From sand on the Riga coast.

Bacillus graveolens Bordoni-Uffreduzzi. (Bordoni-Uffreduzzi, Fortschr. d. Med., *4*, 1886, 157; not *Bacillus graveolens* Russell, Ztschr. f. Hyg., *11*, 1892, 99; not *Bacillus graveolens* Gottheil, Cent. f. Bakt., II Abt., *7*, 1901, 496; *Bacterium graveolens* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 108.) From skin between the toes.

Bacillus grawitzi Trevisan. (Bacillus der Acne Contagiosa des Pferdes, Dieckerhoff and Grawitz, Arch. f. path. Anat., *102*, 1885, 148; Trevisan, I generi e le specie delle Batteriacee, Milan, 1889, 13; *Bacillus acnes contagiosae* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 445; *Bacterium acnes contagiosae* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 89; *Bacterium acnes* Migula, Syst. d. Bakt., *2*, 1900, 385; *Bacterium grawitzii* Chester, Man. Determ. Bact., 1901, 154.) From acne pustles in horses.

Bacillus griseus Migula. (Grauer Bacillus, Keck, Inaug. Diss., Dorpat, 1891, 51; Migula, Syst. d. Bakt., *2*, 1900, 785.) From water.

Bacillus haematoides Wright. (Wright, Mem. Nat. Acad. Sci., *7*, 1895, 448; *Bacterium haematoides* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 115.) From river water.

Bacillus hajeki Trevisan. (*Bacillus foetidus ozaenae* Hajek, Münch. med. Wochnschr., 1887 and Berliner klin. Wochnschr., 1888, 662; Trevisan, I generi e le specie delle Batteriacee, 1889, 16; *Bacillus ozaenae* Migula, Syst. d. Bakt., *2*, 1900, 645; not *Bacillus ozaenae* Abel, Cent. f. Bakt., *13*, 1893, 167; *Bacterium foetidus ozaenae* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 134.) From nasal mucus in human ozena.

Bacillus halobicus Horowitz-Wlassowa. (Ztschr. f. Unters. d. Lebensm., *62*, 1931, 597.) From brines used in salting fish.

Bacillus halophilus Russell. (Russell, Ztschr. f. Hyg., *11*, 1891, 200; *Bacterium halophilus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 93 and 135.) From sea water and marine mud.

Bacillus havaniensis Migula. (*Bacillus havaniensis liquefaciens* Sternberg, Man. of Bact., 1893, 686; *Bacterium havaniensis liquefaciens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 97; Migula, Syst. d. Bakt., *2*, 1900, 725; not *Bacillus havaniensis* Sternberg, *loc. cit.*, 718.) From the skin.

Bacillus helvolus granulatus Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 374.) Apparently a variety of *Bacillus helvolus* Zimmermann.

Bacillus heminecrobiophilus Arloing. (Compt. rend. Acad. Sci., Paris, *107*, 1888, 1169 and *108*, 1889, 458.) From the

lymph glands of an experimental guinea pig.

Bacillus hepaticus fortuitus Sternberg. (Sternberg, Man. of Bact., 1893, 649; *Bacterium hepaticus fortuitus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 136.) From the liver of a yellow-fever cadaver.

Bacillus herrmanni Migula. (Ein neuer Kapselbacillus, Herzfeld and Herrmann, Hyg. Rundschau, *5*, 1895, 642; Migula, Syst. d. Bakt., *2*, 1900, 647.) From a nasal secretion.

Bacillus hofmanni Migula. (Hofmann, Wochnschr. f. Forstwirtsch., 1891, No. 1-6 and No. 35-39; Migula, Syst. d. Bakt., *2*, 1900, 742.) From the larvae of the nun moth (*Lymantria monacha*).

Bacillus hudsonii Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 369; *Bacterium hudsonii* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 106.) From air.

Bacillus humilis Trevisan. (Bactérie de l'air No. 1, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 140; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From air.

Bacillus hydrocharis Trevisan. (Bacille de l'eau *c*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 168; Trevisan, I generi e le specie delle Batteriacee, 1889, 19.) From water.

Bacillus hydrosulfureus Migula. (*Bacillus oogenes hydrosulfureus* ζ Zörkendörfer, Arch. f. Hyg., *16*, 1893, 388; Migula, Syst. d. Bakt., *2*, 1900, 695.) From hens' eggs.

Bacillus icterogenes Kruse. (Guarnieri, Acc. med. Roma, 87/88 and Vincent, Semaine médicale, 1893, 29; Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 372; *Bacterium icterogenes* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 69.) From the liver and blood in cases of acute yellow atrophy.

Bacillus incanus Pohl. (Pohl, Cent. f. Bakt., *11*, 1892, 142; *Bacterium incanus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 99; *Bacterium incannum* (sic) Chester, Man. Determ. Bact., 1901, 157.) From swamp water.

Bacillus indigogenus Alvarez. (Alvarez, Compt. rend. Acad. Sci., Paris, *105*, 1887, 286; *Bacterium indigogenus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 136.) From an infusion of leaves of the indigo plant.

Bacillus innesi Trevisan. (Bacille de l'éléphantiasis des Arabes, Innes, Bull. Ist. Égypt. de 1886, Cairo, 1887; Trevisan, I generi e le specie delle Batteriacee, 1889, 13.) From the blood in cases of elephantiasis in Egypt.

Bacillus inodorus Trevisan. (I generi e le specie delle Batteriacee, 1889, 16.) From pus.

Bacillus intestinus motilis Sternberg. (Sternberg, Man. of Bact., 1893, 649; *Bacterium intestinus motilis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 74.) From intestines of yellow fever cadavers.

Bacillus inutilis Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 364.) From air.

Bacillus kappa Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 375.) From diseased larva of a moth (*Scoliopteryx libatrix*).

Bacillus klebsii Trevisan. (*Bacillus typhosus* Klebs, Handb. d. path. Anat., 1880 and Arch. f. exper. Pathol. u. Pharmac., *13*, 1881, Heft 5-6; Trevisan, Car. di alc. nuov. gen. di Battr., 1885, 10; Trevisan, I generi e le specie delle Batteriacee, 1889, 14; not *Bacillus typhosus* Zopf, Die Spaltpilze, 3 Aufl., 1885, 126.) From an intestinal necrosis.

Bacillus kleckii Migula. (*Bacillus butyri II*, v. Klecki, Cent. f. Bakt., *15*, 1894, 360; Migula, Syst. d. Bakt., *2*, 1900, 810.) From rancid butter.

Bacillus kleinii Trevisan. (Bacillus de la diarrhée choleriforme, Klein, Micro-organisms and Disease, 1885, 87; Trevisan, in DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 946; not *Bacillus kleinii* Migula, Syst. d. Bakt., *2*, 1900, 766; not *Bacillus kleinii* Buchanan and Hammer, Iowa Agr. Exp. Sta. Res. Bull. 22, 1915, 276.) From the blood in fatal cases of choleraic diarrhoea.

Bacillus kleinii Migula. (Ein neuer

Bacillus des malignen Oedems, Klein, Cent. f. Bakt., *10*, 1891, 186; *Bacillus pseudo-oedematis maligni* Sanfelice, Ztschr. f. Hyg., *14*, 1893, 353; *Bacillus oedematis aerobicus* Sternberg, Man. of Bact., 1893, 465; *Bacillus oedematis aerobius* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 244; *Bacterium oedematis aerobius* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 75; Migula, Syst. d. Bakt., *2*, 1900, 766; not *Bacillus kleinii* Trevisan, in De-Toni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 946; not *Bacillus kleinii* Buchanan and Hammer, Iowa Agr. Exp. Sta. Res. Bull. 22, 1915, 276; *Bacillus aerobius* Chester, Man. Determ. Bact., 1901, 221.) From a guinea pig inoculated with soil.

Bacillus kornii Chester. (Bacillus bei einem Leberabscess, Korn, Cent. f. Bakt., *21*, 1897, 438; Chester, Man. Determ. Bact., 1901, 252.) From a case of liver abscess.

Bacillus lactis Chester. (Bacillus b, Guillebeau, Ann. Microg., *11*, 1898–1899, 225; Chester, Man. Determ. Bact., 1901, 238; not *Bacillus lactis* Neide, Cent. f. Bakt., II Abt., *12*, 1904, 337.) From milk.

Bacillus lactofoetidus Migula. (*Bacillus foetidus lactis* Jensen, 22de Beretning fra den Kgl. Veterin og Landbohöjskoles Laboratorium for landökonomiske Forsoeg, Copenhagen, 1891, 15; Migula, Syst. d. Bakt., *2*, 1900, 740.) From tainted milk and butter.

Bacillus lanceolatus Mattes. (Sitzungsber. d. Gesells. z. Beförderung d. gesam. Naturw. z. Marburg, *62*, 1927, 381–417.) From benign foulbrood of bees (*Apis mellifera*).

Bacillus larvicida Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 377; *Bacterium larvicida* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 103.) From the exudate of a diseased larva of a moth (*Clisiocampa fragilis*).

Bacillus lassari Trevisan. (Bacillus des lichen ruber, Lassar, see Flügge, Die Mikroorganismen, 2 Aufl., 1886, 239; Trevisan, I generi e le specie delle Batteriacee, 1889, 14.) From lichen ruber, a skin disease.

Bacillus lentiformis Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 418.) From the stomach and intestines of birds.

Bacillus leptinotarsae White. (Proc. Ent. Soc. Wash., *30*, 1928, 71; Jour. Agr. Res., *51*, 1935, 223.) From diseased larvae of the Colorado potato-beetle (*Leptinotarsa decemlineata*).

Bacillus lesagei Trevisan. (Bacille de la diarrhée verte des enfants, Lesage, Bull. Acad. Méd., Paris, October, 1887; Trevisan, I generi e le specie delle Batteriacee, 1889, 14; *Bacillus viridis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 292; *Bacterium viridis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 118.) Associated with green diarrhoea of children.

Bacillus limbatus Migula. (*Bacillus limbatus butyri* von Klecki, Cent. f. Bakt., *15*, 1894, 359; Migula, Syst. d. Bakt., *2*, 1900, 62.) From rancid butter.

Bacillus limicola Russell. (Bot. Gaz., *18*, 1893, 383.) From sea water and marine mud at Woods Hole, Massachusetts.

Bacillus lineatus Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 17.) From larvae of the nun moth (*Lymantria monacha*).

Bacillus lineatus Migula. (Bakterie V, Weigmann and Zirn, Cent. f. Bakt., *15*, 1894, 467; Migula, Syst. d. Bakt., *2*, 1900, 806; not *Bacillus lineatus* Eckstein, Ztschr. f. Forst- und Jagdwesen, *26*, 1894, 17.) From soapy milk.

Bacillus liparis Paillot. (Compt. rend. Acad. Sci., Paris, *164*, 1917, 527.) From larvae of the gypsy moth (*Porthetria (Lymantria) dispar*).

Bacillus liquefaciens Doyen. (*Bacillus urinae liquefaciens* Doyen, Jour. d. connaiss. médic., 1889, 108; Doyen, *idem*; not *Bacillus liquefaciens* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 112.) From urine.

Bacillus liquefaciens Migula. (*Bacil-*

lus sulcatus liquefaciens Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 318; Migula, Syst. d. Bakt., *2*, 1900, 723; not *Bacillus liquefaciens* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 112.) From water.

Bacillus liquefaciens albus Vaughan. (Amer. Jour. Med. Sci., *104*, 1892, 185.) From water.

Bacillus liquefaciens communis Sternberg. (Sternberg, Man. of Bact., 1893, 686; *Bacterium liquefaciens communis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 137.) From the feces of yellow fever patients. Considered by Chester (*loc. cit.*, 91) to be synonymous with *Bacillus aquatilis communis* Kruse.

Bacillus liquidus communis Sternberg. (Manual of Bact., 1893, 686.) From feces.

Bacillus litorosus Russell. (Bot. Gaz., *18*, 1893, 444.) From sea water and marine mud at Woods Hole, Massachusetts.

Bacillus loxiacida Tartakowsky. (Arch. d. Veterinarwiss., 1888; quoted from Chester, Man. Determ. Bact., 1901, 211.) Associated with an infectious disease of crossbills.

Bacillus lucidus Migula. (No. 8, Lembke, Arch. f. Hyg., *26*, 1896, 303; Migula, Syst. d. Bakt., *2*, 1900, 674.) From feces.

Bacillus lupi Trevisan. (I generi e le specie delle Batteriacee, 1889, 12.) From lupus, a skin disease.

Bacillus lupini Migula. (*Bacillus tuberigenus 7*, Gonnermann, Landwirtsch. Jahrb., *23*, 1894, 657; Migula, Syst. d. Bakt., *2*, 1900, 793.) From root nodules on lupine.

Bacillus lustigii Trevisan. (Bacillo inoffensivo del Mytilus edulis, Lustig, Arch. per le sci. med., *12*, 1887, 17; Trevisan, see DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 958; not *Bacillus lustigii* Carbone and Venturelli, Boll. Ist. Sieroter., Milan, *4*, 1925, 59.) From the liver of a mussel (*Mytilus edulis*).

Bacillus luteo-albus Beijerinck. (Botan. Zeit., *46*, 1888, 749.) From root nodules on legumes.

Bacillus lutetiensis Chester. (*Bacillus violaceus lutetiensis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 311; Chester, Man. Determ. Bact., 1901, 306.) From water.

Bacillus luteus Flügge. (Die Mikroorganismen, 2 Aufl., 1886, 290; not *Bacillus luteus* von Dobrzyniecki, Cent. f. Bakt., I Abt., *21*, 1897, 835; not *Bacillus luteus* Garbowski, Cent. f. Bakt., II Abt., *19*, 1907, 641.) From air.

Bacillus lymantriae Picard and Blanc. (Picard and Blanc, Compt. rend. Acad. Sci., Paris, *157*, 1913, 80; *Bacillus lymantria α* Paillot, *ibid.*, *168*, 1919, 258; *Bacillus (Bacterium) lymantriae* Paillot, L'infection chez les insectes, 1933, 131; *Coccobacillus lymantriae* Steinhaus, Catalogue of Bacteria Associated Extracellularly with Insects and Ticks, Minneapolis, 1942, 64 and 183.) From diseased larvae of the gypsy moth (*Porthetria (Lymantria) dispar*).

Bacillus lymantriae β Paillot. (Compt. rend. Acad. Sci., Paris, *168*, 1919, 258.) From diseased larvae of the gypsy moth (*Porthetria (Lymantria) dispar*).

Bacillus lymantricola adiposus Paillot. (Compt. rend. Acad. Sci., Paris, *168*, 1919, 258; *Bacterium lymantricola adiposus* Paillot, L'infection chez les insectes, 1933, 135.) From caterpillars of *Porthetria (Lymantria) dispar*.

Bacillus madidus Migula. (No. 5, Lembke, Arch. f. Hyg., *26*, 1896, 300; Migula, Syst. d. Bakt., *2*, 1900, 812.) From bread.

Bacillus maggiorae DeToni and Trevisan. (*Bacillus B*, Maggiora, Giorn. Soc. ital. d'Igiene, *11*, 1889, 340; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 968.) From the skin of the human foot and from air.

Bacillus major Doyen. (*Bacillus urinae major* Doyen, Jour. d. connaiss. médic., 1889, 107; Doyen, *ibid.*, 108.) From urine.

Bacillus malariae Klebs and Tommasi-Crudeli. (Arch. f. exper. Pathol., *2*,

1879.) From swamp soil. See Sternberg, Man. of Bact., 1893, 523.

Bacillus mammitidis Migula. (*Bacillus a*, Guillebeau, Ann. de Microg., *2*, 1890, No. 8; Migula, Syst. d. Bakt., *2*, 1900, 810.) From the milk of cows having mastitis.

Bacillus manganicus Beijerinck. (Folia Microbiol., Delft, *2*, 1913, 130.) From soil. Motile. Is able to oxidize manganese carbonate.

Bacillus margarineus Migula. (*Diplococcus capsulatus margarineus* Jolles and Winkler, Ztschr. f. Hyg., *20*, 1895, 103; Migula, Syst. d. Bakt., *2*, 1900, 694.) From margarine.

Bacillus maricola Migula. (*Halibacterium polymorphum* Fischer, Die Bakterien des Meeres, 1894, 36; Migula, Syst. d. Bakt., *2*, 1900, 709.) From sea water.

Bacillus marsilliensis Kruse. (Bacillus of Marseilles swine plague, Rietsch and Jobert, Compt. rend. Acad. Sci., Paris, *106*, 1888, 1096; Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 405; *Bacterium marsiliensis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 67.) Associated with a disease of swine.

Bacillus martinez Sternberg. (Sternberg, Man. of Bact., 1893, 651; *Bacillus martinezii* Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 364; *Bacterium martinezii* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 83.) From the liver of a yellow fever cadaver. Dyar isolated an organism from the air to which he applied Sternberg's name as the descriptions of the two species did not disagree.

Bacillus meleagridis Migula. (McFadyean, Jour. Comp. Path. and Therap., *6*, 1893, 334; Migula, Syst. d. Bakt., *2*, 1900, 770; *Bacillus meleagris* Chester, Man. Determ. Bact., 1901, 220.) The cause of epizootic pneumo-carditis in turkeys.

Bacillus melleus Schroeter. (In Cohn, Kryptog. Flora v. Schlesien, *3*, 1, 1886, 158.) From feces and other sources.

Bacillus melolonthae Chatton. (Compt. rend. Acad. Sci., Paris, *156*, 1913, 1708.) From diseased cockchafers (*Melolontha melolontha*).

Bacillus melolonthae liquefaciens α, β and γ Paillot. (Compt. rend. Acad. Sci., Paris, *167*, 1918, 1046; Annales des Épiphyties, *8*, 1922, 108–110; *B. melolonthae liquefaciens* α, β and γ Paillot, L'infection chez les insectes, 1933, 173, 196 and 189 respectively. According to the index the *B.* is used for *Bacterium*.) From diseased cockchafers (*Melolontha melolontha*).

Bacillus melolonthae non-liquefaciens α, β and γ Paillot. (Compt. rend Acad. Sci., Paris, *163*, 1916, 553; Annales des Épiphyties, *8*, 1922, 111–113.) From diseased cockchafer (*Melolontha melolontha*).

Bacillus melolonthae non-liquefaciens δ Paillot. (Compt. rend Acad. Sci., Paris, *167*, 1918, 1046; Annales des Épiphyties, *8*, 1922, 113.) From diseased cockchafers (*Melolontha melolontha*).

Bacillus melolonthae non-liquefaciens ϵ Paillot. (Compt. rend. Acad. Sci., Paris, *169*, 1919, 1122; Annales des Épiphyties, *8*, 1922, 114.) From diseased cockchafers (*Melolontha melolontha*).

Bacillus membranaceus Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 407.) From the stomach and intestines of a bird.

Bacillus meningitidis Migula. (*Bacillus aerogenes meningitidis* Centanni, Arch. per le scienze mediche, *17*, 1893, No. 1; *Bacterium meningitidis aerogenes* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 96; Migula, Syst. d. Bakt., *2*, 1900, 642; *Bacillus radiatus* Chester, Man. Determ. Bact., 1901, 241.) From two cases of meningitis.

Bacillus metabolicus DeToni and Trevisan. (*Bacillus H*, Maggiora, Giorn. Soc. ital. d'Igiene, *11*, 1889, 350; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 968.) From the skin of the human foot.

Bacillus metaflavus Castellani. (Proc. Soc. Expt. Biol. and Med., *25*, 1928, 539.) From the human skin.

Bacillus minimus Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 16.) From caterpillars of the nun moth (*Lymantria monacha*).

Bacillus minutissimus Migula. (*Bacillus aureus minutissimus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 441; Migula, Syst. d. Bakt., *2*, 1900, 833.) From air.

Bacillus mitidus Henrici. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 29.) From Gouda cheese.

Bacillus mobilissimus Migula. (*Bacillus oogenes hydrosulfureus δ*, Zörkendörfer, Arch. f. Hyg., *16*, 1893, 390; Migula, Syst. d. Bakt., *2*, 1900, 791.) From hens' eggs.

Bacillus mollis Doyen. (*Bacillus urinae mollis* Doyen, Jour. d. connaiss. médic., 1889, 107; Doyen, *ibid.*, 108.) From urine.

Bacillus morulans Boucquet. (Phytopath., *7*, 1917, 286.) From diseased sugar beets. Associated with curly top of sugar beet.

Bacillus nottei Trevisan. (Motte and Protopopoff, Wratsch., 1887, No. 21, 415; abst. in Cent. f. Bakt., *2*, 1887, 450; Trevisan, I generi e le specie delle Batteriacee, 1889, 13.) Associated with a rabies-like disease of rabbits and dogs.

Bacillus (?) *multiformis* Castellani. (Proc. Soc. Exp. Biol. and Med., *25*, 1928, 539.) From the human skin.

Bacillus murinus Chester. (Bacillus of rat plague, Issatschenko, Cent. f. Bakt., *23*, 1898, 873; Chester, Man. Determ. Bact., 1901, 224; not *Bacillus murinus* Schroeter, in Cohn, Kryptog. Flora v. Schlesien, *3*, 1886, 162.) From the spleen and liver of rats attacked in St. Petersburg by a plague.

Bacillus mycogenes Edwards. (Jour. Inf. Dis., *2*, 1905, 431; *Bacterium mucogenum* Edwards, *idem.*) From exudate of wound infections. Belongs to the *Bacillus mucosus capsulatus* group.

Bacillus mytili Trevisan. (Bacillo patogeno del Mytilus edulis, Lustig, Arch. per le Sci. med., *12*, 1887, 17; Trevisan, see DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 958.) From the liver of a mussel (*Mytilus edulis*).

Bacillus naphthalinicus liquefaciens Tausson. (Planta, *4*, 1927, 214.) From oil-soaked soils at Baku, Russia. Oxidizes naphthalene.

Bacillus naphthalinicus non-liquefaciens Tausson. (Planta, *4*, 1927, 214.) From oil-soaked soils at Baku, Russia. Oxidizes naphthalene.

Bacillus nebulosus Migula. (*Bacillus tuberigenus 3*, Gonnermann, Landwirtsch. Jahrb., *23*, 1894, 656; Migula, Syst. d. Bakt., *2*, 1900, 844; not *Bacillus nebulosus* Wright, Mem. Nat. Acad. Sci., 7, 1894, 465; not *Bacillus nebulosus* Hallé, Thèse de Paris, 1898; not *Bacillus nebulosus* Vincent, Ann. Inst. Past., *21*, 1907, 69; not *Bacillus nebulosus* Goresline, Jour. Bact., *27*, 1934, 52.) From root nodules on lupine.

Bacillus necans Trevisan. (Bacille consécutif au charbon, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 231; Trevisan, I generi e le specie delle Batteriacee, 1889, 14.) From rabbits dead from anthrax.

Bacillus nephriticus Trevisan. (Bacille de la néphrite bactérienne, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 373; Trevisan, I generi e le specie delle Batteriacee, 1889, 14.) From urine in cases of nephritis.

Bacillus neurotomae Paillot. (Compt. rend. Acad. Sci., Paris, *178*, 1924, 247; probably identical with *Bacterium neurotomae* Paillot, L'infection chez les insectes, 1933, 146.) From diseased larvae of a sawfly (*Neurotoma nemoralis* L.).

Bacillus nitens Migula. (*Bacillus oogenes hydrosulfureus ι*, Zörkendörfer, Arch. f. Hyg., *16*, 1893, 390; Migula, Syst. d. Bakt., *2*, 1900, 793.) From hens' eggs.

Bacillus ochroleucus Migula. (*Bacillus oogenes hydrosulfureus ε*, Zörkendörfer, Arch. f. Hyg., *16*, 1893, 387; Migula, Syst. d. Bakt., *2*, 1900, 844.) From hens' eggs.

Bacillus odoratus Weiss. (Weiss, Arb. bakt. Inst. Karlsruhe, *2*, 1902, 243; not

Bacillus odoratus Migula, Syst. d. Bakt., *2*, 1900, 686; *Bacterium odoratum* Omeliansky, Jour. Bact., *8*, 1923, 394.) From fermented beets.

Bacillus odorificans Migula. (Weisser stinkender Bacillus, Maschek, Bakt. Untersuch. d. Leitmeritzer Trinkwässer, Leitmeritz, 1887; Migula, Syst. d. Bakt., *2*, 1900, 711.) From water. Intense odor resembling that of liquid manure.

Bacillus odorificus Omeliansky. (Jour. Bact., *8*, 1923, 393.) Probably intended for *Bacillus odorificans* Migula.

Bacillus odorus Henrici. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 30.) From cream cheese.

Bacillus oonergasius Trevisan. (Bacille du mucus intestinal normal *c*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 153; Trevisan, I generi e le specie delle Batteriacee, 1889, 15.) From normal intestinal mucus.

Bacillus osteomyeliticus Trevisan. (Bacille de l'ostéomyélite, Rodet; Trevisan, 1884; see Trevisan, I generi e le specie delle Batteriacee, 1889, 16.) From a case of osteomyelitis.

Bacillus oxylacticus Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 369.) Culture received from Kràl's laboratory labeled *Bacillus oxylacticus;* also from air.

Bacillus pallescens Migula. (*Bacillus luteus pallescens* Losski, Inaug. Diss., Dorpat, 1893, 44; Migula, Syst. d. Bakt., *2*, 1900, 819.) From garden soil.

Bacillus pallidus Schroeter. (Schroeter, in Cohn, Kryptog. Flora v. Schlesien, *3*, 1, 1886, 158; not *Bacillus pallidus* Bredemann and Heigener, Cent. f. Bakt., II Abt., *93*, 1935, 98.) From cooked potato.

Bacillus panificans Laurent. (Bull. Soc. R. Bot. Belg., 1885, 175.) From fermenting dough.

Bacillus pannosus Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 409.) From the stomachs and intestines of birds.

Bacillus pansinii Migula. (Bacillus No. 12, Pansini, Arch. f. path. Anat., *122*, 1890, 477; Migula, Syst. d. Bakt., *2*, 1900, 660.) From sputum.

Bacillus parallelus Edson and Carpenter. (Vermont Agr. Exp. Sta. Bull. 167, 1912, 593.) From maple sap. Capsulated. At times feebly fluorescent.

Bacillus paullulus Trevisan. (Bacille de l'air *d*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 149; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From air.

Bacillus pectinophorae White and Noble. (Jour. Econ. Entomol., *29*, 1936, 123.) From diseased pink bollworm larvae (*Pectinophora gossypiella*).

Bacillus pediculi Arkwright and Bacot. (Parasitol., *13*, 1921, 26.) From the genital apparatus of the louse (*Pediculus humanus*).

Bacillus pellucidus Doyen. (*Bacillus urinae pellucidus* Doyen, Jour. d. connaiss. médic., 1889, 107; Doyen, *ibid.*, 108; not *Bacillus pellucidus* Kern, Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 404.) From urine.

Bacillus perlibratus Beijerinck. (Cent. f. Bakt., *14*, 1893, 831.) From a bean infusion.

Bacillus perronciti Trevisan. (Bacillo della pneumonite nodulare dei vitellini, Perroncito, Parassiti dell'uomo e degli animali utili, 1882, 52; Trevisan, I generi e le specie delle Batteriacee, 1889, 13.) From pulmonary nodules in contagious pneumonia in calves.

Bacillus petersii Migula. (*Bacterium B*, Peters, Botan. Zeit., *47*, 1889; *Bacterium acidi lactici* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 357; not *Bacterium acidi lactici* Zopf, Die Spaltpilze, 2 Aufl., 1884, 60; not *Bacterium acidi lactici I* and *II* Grotenfelt, Fortschr. d. Med., 7, 1889, 123; not *Bacterium acidi lactici* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., *1*, 1a, 1895, 25; Migula, Syst. d. Bakt., *2*, 1900, 799.) From fermenting dough. Probably *Bacterium levans* Wolffin.

Bacillus phenanthrenicus bakiensis Tausson. (Planta, *5*, 1928, 239.) From

soil. Utilizes phenanthrene and other hydrocarbons.

Bacillus phenanthrenicus guricus Tausson. (Planta, *5*, 1928, 239.) From soil. Utilizes phenanthrene and other hydrocarbons.

Bacillus phenologenes Berthelot. (Ann. Inst. Past., *32*, 1918, 20.) From feces. Forms phenol.

Bacillus pieris agilis Paillot. (Compt. rend. Acad. Sci., Paris, *168*, 1919, 477.) From diseased caterpillars of the cabbage butterfly (*Pieris brassicae*).

Bacillus pieris fluorescens Paillot. (Compt. rend. Acad. Sci., Paris, *168*, 1919, 477; Ann. Épiphyt., *8*, 1922, 124.) From diseased caterpillars of the cabbage butterfly (*Pieris brassicae*).

Bacillus pieris liquefaciens Paillot. (Compt. rend. Acad. Sci., Paris, *168*, 1919 477; *Bacillus pieris liquefaciens α* Paillot, Annales des Épiphyties, *8*, 1922, 125.) From diseased caterpillars of the cabbage butterfly (*Pieris brassicae*). If this author followed his usual custom, this is identical with his *Bact. pieris liquefaciens* in his book, L'infection chez les insectes, 1933, 135.

Bacillus pieris liquefaciens β Paillot. (Annales des Épiphyties, *8*, 1922, 126; name occurs as *B. pieris liquefaciens β* Paillot, L'infection chez les insectes, 1933, 299. According to the index *B.* stands for *Bacterium*.) From diseased caterpillars of the cabbage butterfly (*Pieris brassicae*).

Bacillus pieris non-liquefaciens α Paillot. (Compt. rend. Acad. Sci., Paris, *168*, 1919, 477; *B. pieris non-liquefacins α* Paillot, L'infection chez les insectes, 1933, 135 ff. According to the index *B.* stands for *Bacterium*.) From the cabbage butterfly (*Pieris brassicae*).

Bacillus pieris non-liquefaciens β Paillot. (Compt. rend. Acad. Sci., Paris, *168*, 1919, 474; *B. pieris non-liquefaciens β* Paillot, L'infection chez les insectes, 1933, 299; according to the index, the *B.* stands for *Bacterium*.) From diseased caterpillars of the cabbage butterfly (*Pieris brassicae*).

Bacillus pleomorphus Migula. (*Bacillus murisepticus pleomorphus* Karliński, Cent. f. Bakt., *5*, 1889, 193; *Bacterium murisepticus pleomorphus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 102; Migula, Syst. d. Bakt., *2*, 1900, 649; *Bacillus murisepticus* Chester, Man. Determ. Bact., 1901, 247; not *Bacillus murisepticus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 250.) From pus.

Bacillus plicatus Frankland and Frankland. (Philos. Trans. Roy. Soc. London, *178*, B, 1888, 273; not *Bacillus plicatus* Zimmermann, see Frankland and Frankland, Microorganisms in Water, London, 1894, 459.) From air.

Bacillus plumbeus Migula. (Grau verflüssigender Bacillus, Keck, Inaug. Diss., Dorpat, 1890, 54; Migula, Syst. d. Bakt., *2*, 1900, 719.) From water.

Bacillus pneumo-enteritidis murium Schilling. (Arb. a. d. kaiserl. Gesundheitsamte, *18*, Heft 1, 1900.) From a disease of rats.

Bacillus pneumosepticus Kruse. (Pneumonie bacillus, Klein, Cent. f. Bakt., *5*, 1889, 625; Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 408; not *Bacillus pneumosepticus* Babes, Progrès méd. roumain., *6*, 1889; *Bacterium pneumosepticus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 76.) From rusty sputum. Considered the cause of an epidemic of pneumonia in England.

Bacillus poelsii Chester. (Vleeschvergiftung te Rotterdam, Poels and Dhont; Tweede Rapport van de des Kundigen; Chester, Man. Determ. Bact., 1901, 209.) From beef in meat poisoning.

Bacillus pomodoriferus Castellani. (Proc. Soc. Exp. Biol. and Med., *25*, 1928, 540.) From the urine in a case of cystitis and from feces.

Bacillus poncei Glaser. (Ann. Entomol. Soc. Am., *11*, 1918, 19.) Pathogenic for the insects, *Melanoplus femur-rubrum* and *Encoptolopus sordidus*.

Bacillus praepollens Maassen. (Arb. a. d. kaiserl. Gesundheitsamte, *15*,

1899, 507.) From sweat of a cholera patient.

Bacillus primus fullesi Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 360; *Bacterium primus fullesi* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 72.) From a leaf of the pitcher plant (*Sarracenia purpurea*). Regarded by Dyar as identical with Bacillus No. 1, isolated by Fulles (Ztschr. f. Hyg., *10*, 1891, 250) from forest soil.

Bacillus promissus Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 420.) From the intestines of a dove.

Bacillus proteidis Paillot. (Annales des Épiphyties, *8*, 1922, 130.) From diseased larvae of the cabbage butterfly (*Pieris brassicae*).

Bacillus protervus Trevisan. (Bacillus der Conjunctivalsack *d*, Fick, Microorgan. in Conjunctivalsack, Wiesbaden, 1887; Trevisan, I generi e le specie delle Batteriacee, 1889, 17.) From the conjunctiva.

Bacillus pruddeni Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 378.) Found by Dr. Prudden in a case of cystitis.

Bacillus pseudomirabilis Migula. (*Bacillus mirabilis* Tataroff, Inaug. Diss., Dorpat, 1891, 18; Migula, Syst. d. Bakt., *2*, 1900, 818.) From water. According to Migula, Tataroff mistakenly believed that he had Zimmermann's *Bacillus mirabilis*.

Bacillus pseudotuberculosis Migula. (Du Cazal and Vaillard, Ann. Inst. Past., *5*, 1891, 353; *Bacillus pseudotuberculosis liquefaciens* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 455; Migula, Syst. d. Bakt., *2*, 1900, 644.) From nodules in the peritoneum.

Bacillus pseudotyphosus Kruse. (Lösener, Arb. a. d. kaiserl. Gesundheitsamte, *11*, 1895, 2; Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 383; *Bacterium pseudotyphosus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 73; not *Bacterium pseudotyhposum* Migula, Syst. d. Bakt., *2*, 1900, 428.) Isolated by Lösener from peritoneal fluid of a hog, from water, etc.; by Pansini from a liver abscess; by Babes from a variety of sources. Kruse used this as a general name for any typhoid-like organism.

Bacillus pulpae pyogenes Miller. (Miller, Die Mikroorganismen der Mundhöhle, Leipzig, 1889, 219.) From gangrenous pulp of a tooth.

Bacillus punctatus Shul'gina and Kalinicker. (Rep. Bur. Appl. Ent., Leningrad, *3*, No. 1, 1927, 99–104, quoted from Steinhaus, Bact. Assoc. Extracell. with Insects and Ticks, Minneapolis, 1942, 79; not *Bacillus punctatus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, I Reihe, 1890, 38.) From the locust (*Locusta migratoria*).

Bacillus puncticulatus Migula. (No. 16, Lembke, Arch. f. Hyg., *29*, 1897, 322; Migula, Syst. d. Bakt., *2*, 1900, 678.) From feces.

Bacillus putidus Kern. (Kern, Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 400; not *Bacillus putidus* Chester, Man. Determ. Bact., 1901, 237; not *Bacillus putidus* Weinberg et al., Les Microbes Anaérobies, 1937, 790.) From the stomach and intestines of birds.

Bacillus pylori Ford. (Studies from the Royal Victoria Hosp., Montreal, *1* (5), 1903, 44; also see Jour. Med. Res., *1*, 1901, 217.) From the stomach.

Bacillus pyogenes Lucet. (*Bacillus pyogenes bovis* Lucet, Ann. Inst. Past., *7*, 1893, 372; Lucet, *ibid.*, 328; not *Bacillus pyogenes* Glage, Ztschr. f. Fleish. u. Milchhyg., *13*, 1903, 166.) From bovine abscesses.

Bacillus pyogenes var. *liquefaciens* Chester. (*Bacillus pyogenes foetidus liquefaciens* Lanz, Cent. f. Bakt., *14*, 1893, 277; *Bacterium pyogenes foetidus liquefaciens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 92; Chester, Man. Determ. Bact., 1901, 235.) From a brain abscess after otitis media.

Bacillus pyogenes soli Bolton. (Ann. Jour. Med. Sci., June, 1892; quoted from Sternberg, Man. of Bact., 1893, 728.) From garden earth.

Bacillus pyrameis I and *II*, Paillot. (Compt. rend. Acad. Sci., Paris, *157*,

1913, 611.) From tissues and blood of the caterpillar of *Pyrameis* (*Vanessa*) *cardui*. A coccobacillus.

Bacillus radians Trevisan. (Bactérie de l'air No. 2, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 140; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From air.

Bacillus ramificans Migula. (Bacillus No. 9, Pansini, Arch. f. path. Anat., *122*, 1890, 445; Migula, Syst. d. Bakt., *2*, 1900, 661; *Bacillus pansini* Chester, Man. Determ. Bact., 1901, 246; not *Bacillus pansinii* Migula, *loc. cit.*, 660.) From sputum.

Bacillus recuperatus Wright. (Wright, Mem. Nat. Acad. Sci., *7*, 1895, 439; *Bacterium recuperatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 74.) From Schuylkill River water.

Bacillus repazii Herter. (*Bacillus moliniformis* Repazi, Compt. rend. Soc. Biol., Paris, *68*, 1910, 410; not *Bacillus moniliformis* Garnier, Arch. Méd. expér. et Anat. pathol., *19*, 1908, 785; Herter, in Just's Botan. Jahresber., *39*, 2 Abt., Heft 4, 1915, 750.) From a lung abscess.

Bacillus rhinitis atrophicans Paulsen. (Paulsen, quoted from Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 79; *Bacterium rhinitis atrophicans* Chester, *ibid.*, 141.) From nasal secretions.

Bacillus rigidus apis White. (Jour. Path. and Bact., *24*, 1921, 70.) From intestine of bee.

Bacillus rogerii Migula. (*Bacillus septicus putidus* Roger, Revue de Méd., 1891, 10; Migula, Syst. d. Bakt., *2*, 1900, 647; *Bacterium septicus putidus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 92; *Bacillus putidus* Chester, Man. Determ. Bact., 1901, 237; not *Bacillus putidus* Kern, Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 400; not *Bacillus putidus* Weinberg et al., Les Microbes Anaérobies, 1937, 790.) From the spinal fluid and liver in a case of cholera.

Bacillus rosaceus Migula. (*Bacillus rosaceus margarinicus* Jolles and Winkler, Ztschr. f. Hyg., *20*, 1895, 105; Migula, Syst. d. Bakt., *2*, 1900, 859.) From margarine. Red pigment.

Bacillus rosaceus metaloides Dyar. (*Bacterium rosaceus metaloides* Dowdeswell, Ann. de Micrographie, *1*, 1888–89, 310; Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 376; not *Bacillus rosaceus metalloides* Tataroff, Inaug. Diss., Dorpat, 1891, 65, see Hefferan, Cent. f. Bakt., II Abt., *8*, 1902, 689; *Bacterium rosaceum* Lehmann and Neumann, Bakt. Diag., 2 Aufl., *2*, 1899, 261.) Culture from Dr. Crookshank, London.

Bacillus roseus Migula. (*Halibacterium roseum* Fischer, Die Bakterien des Meeres, 1894, 22; Migula, Syst. d. Bakt., *2*, 1900, 860; *Bacillus roseus fischeri* Nepveux, Thèse, Fac. Pharm. Paris, 1920, 115.) From sea water. Red pigment.

Bacillus rosenthalii Migula. (Rosenthal, Inaug. Diss., Berlin, 1893, 37; Migula, Syst. d. Bakt., *2*, 1900, 656.) From the oral cavity.

Bacillus rubescens Edington. (Ann. Rept. Fish. Board for Scotland, *6*, 1887, 204.) From reddened salted codfish.

Bacillus rubescens Jordan. (Jordan, Massachusetts State Board of Health, Boston, 1890, 835; *Bacterium rubescens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 115.) From sewage.

Bacillus rubiginosus Catiano. (In Cohn, Beitr. z. Biol. d. Pflanzen, *7*, 1896, 538.) From the vagina. Red pigment.

Bacillus rubiformis Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 431.) From the stomach of a bird.

Bacillus rubrofuscus (Fischer) Migula. (*Halibacterium rubrofuscum* Fischer, Die Bakterien des Meeres, 1894, 36; Migula, Syst. d. Bakt., *2*, 1900, 865.) From sea water.

Bacillus rubus (sic) Chester. (Der rother Bacillus, Lustig, Diag. d. Bakt. d. Wassers, 1893, 72; *Bacillus ruber aquatilis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 303; *Bacterium ruber aquatilis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 112; Chester,

Man. Determ. Bact., 1901, 257; *Bacillus lustigi* Chester, *ibid.*, 304.) From water.

Bacillus salmoneus Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 361; *Bacterium salmoneus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 116.) From air.

Bacillus salutarius Metchnikoff. (Metchnikoff, Maladies des hannetons du ble, Odessa (in Russian), quoted from Paillot, L'infection chez les insectes, Paris, 1933, 123.) From diseased larvae of a beetle (*Anisoplia austriaca*).

Bacillus sanguineus Schroeter. (In Cohn, Kryptog. Flora v. Schlesien, *3*, 1, 1886, 156.) From stagnant water.

Bacillus saponaceus Migula. (*Bacillus lactis saponacei* Weigman and Zirn, Cent. f. Bakt., *15*, 1894, 464; Migula, Syst. d. Bakt., *2*, 1900, 692.) From soapy milk.

Bacillus saprogenes Chester. (*Bacillus saprogenes vini VI* Kramer, Bakteriol. Landwirtsch., 1890, 139; Chester, Man. Determ. Bact., 1901, 289.) From diseased wine.

Bacillus saprogenes Trevisan. (*Bacillus saprogenes 1*, Rosenbach, Mikroorganismen bei den Wundinfectionskrankheiten des Menschen, Wiesbaden, 1884; Trevisan, I generi e le specie delle Batteriacee, 1889, 17; *Bacterium saprogenes* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 142.) From feces.

Bacillus sarracenicolus Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 357; *Bacterium sorracenicolus* (sic) Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 81.) From a fresh leaf of the pitcher plant (*Sarracenia purpurea*).

Bacillus scarlatinae Jamieson and Edington. (Jamieson and Edington, Brit. Med. Jour., *1*, 1887, 1265; *Bacillus sudaminis* Trevisan, I generi e le specie delle Batteriacee, 1889, 15.) From the skin of scarlet fever patients.

Bacillus scoticus Migula. (Bacillus der Grouse-disease, Klein, Cent. f. Bakt., *6*, 1889, 36 and 593; *ibid.*, *7*, 1890, 81; Migula, Syst. d. Bakt., *2*, 1900, 768; *Bacillus tetraonis* Chester, Man. Determ. Bact., 1901, 221.) The cause of a disease of grouse (*Lagopus scoticus*) in England and Scotland.

Bacillus secundus Trevisan. (*Bacillus II*, Leube, Arch. f. path. Anat., *100*, 1885, 000; Trevisan, I generi e le specie delle Batteriacee, 1889, 16.) From urine.

Bacillus secundus fullesi Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 359; *Bacterium secundus fulessii* (sic) Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 82; *Bacterium secundus fullesi* Chester, *ibid.*, 143.) From air. Dyar regarded his organism as identical with *Bacillus* No. 2 of Fulles (Ztschr. f. Hyg., *10*, 1891, 250) which was from soil.

Bacillus septicaemiae lophyri Shiperovich. (Shiperovich, Protect. Plants Ukraine, 1925, 41–46; Abs. in Rev. Appl. Ent., A., *14*, 1926, 209.) From larvae of sawflies (*Diprion sertifer*).

Bacillus septicaemicus Trevisan. (Bacillus of septicemia of man, Klein, Microorganisms and Disease, 1885, 84; Trevisan, in DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 945.) From blood and infected lymph glands.

Bacillus septicus hominis Mironoff. (Mironoff, Cent. f. Gynäkol., 1892, 42; *Bacterium septicus hominis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 143.) From a case of septic infection of the uterus. Regarded by Chester (Man. Determ. Bact., 1901, 143) as a synonym of *Pasteurella agrigena* Trevisan.

Bacillus septicus vesicae Clado. (Bull. de la Soc. anatom. de Paris, 1887, 339.) From the urine of a person suffering from cystitis.

Bacillus sericcus Zimmermann. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *2*, 1894, 52.) From water.

Bacillus serratus Migula. (Bacillus No. 14, Pansini, Arch. f. path. Anat., *122*, 1890, 449; Migula, Syst. d. Bakt., *2*, 1900, 658.) From sputum.

Bacillus setosus Migula. (Bacillus No. XVIII, Adametz, Landwirtsch. Jahrb.,

18, 1889, 250; Migula, Syst. d. Bakt., *2*, 1900, 812.) From cheese.

Bacillus silberschmidii Chester. (Bacillus der Fleischvergiftung, Silberschmidt, Correspondenz-Blatt f. Schweizer Aerzte, 1896, No. 8; Chester, Man. Determ. Bact., 1901, 212.) From poisonous meat.

Bacillus simulans Trevisan. (Bacille de l'air *a*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 149; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From air.

Bacillus singularis Losski. (Inaug. Diss., Dorpat, 1893, 45.) From garden soil.

Bacillus siticulosus Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 423.) From the stomachs and intestines of birds.

Bacillus sordidus Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 379; *Bacterium sordidus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 79.) Culture received by Dyar as *Micrococcus sordidus* from Král's laboratory.

Bacillus sordidus Kern. (Arb. Bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 396.) From the stomach of a bird.

Bacillus spermophilinus Issatchenko. (Ein aus Zieselmäusen ausgeschiedener Bacillus, Mereschkowsky, Cent. f. Bakt., *17*, 1895, 742; Issatchenko, Scripta Botanica Hort. Univ. Imp. Petropolitanae, Fasc. XV, 1897; quoted from Migula, Syst. d. Bakt., *2*, 1900, 618.) Apparently resembled *Salmonella typhimurium*. From ground squirrels (*Spermophilus musicus*).

Bacillus spirans Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 222.) From bean infusions.

Bacillus spumosus Zimmermann. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *2*, 1894, 28.) From water.

Bacillus squamosus Pansini. (Arch. f. path. Anat., *122*, 1890, 448.) From sputum.

Bacillus strassmanni Trevisan. (*Bacillus albus cadaveris* Strassmann and Strecker, Ztschr. f. Medicinalbeamte, 1888; Trevisan, I generi e le specie delle Batteriacee, 1889, 17; *Bacterium albus cadaveris* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 102; *Bacillus cadaveris* Migula, Syst. d. Bakt., *2*, 1900, 646.) From the blood of an infant.

Bacillus striatus Doyen. (*Bacillus urinae striatus* Doyen, Jour. d. connaiss. médic., 1889, 107; Doyen, *ibid.*, 108.) From urine.

Bacillus striatus albus von Besser. (Ziegler's Beiträge, *4*, 1889, 331.) Found in normal nasal mucus.

Bacillus striatus flavus von Besser. (Ziegler's Beiträge, *4*, 1889, 331; *Bacterium striatus flavus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 111.) From nasal mucus. Rare.

Bacillus strumitidis Migula. (*Bacillus strumitis α*, Tavel, Ueber die Aetiologie der Strumitis, Basel, 1892, 81; Migula, Syst. d. Bakt., *2*, 1900, 741.) From a case of strumitis.

Bacillus strumitis Tavel. (Tavel, 1889; see Viquerat, Ann. de Micrographie, *2*, 1889–1890, 228.) From acute catarrhal strumitis.

Bacillus subcoccoideus Migula. (*Bacillus aquatilis sulcatus III*, Weichselbaum, Das österreichische Sanitätswesen, 1889, No. 14–23; Migula, Syst. d. Bakt., *2*, 1900, 732.) From water.

Bacillus subflavus Zimmermann. (Zimmermann, Bakt. unserer Trink. u. Nutzwässer, Chemnitz, *1*, 1890, 62; *Bacterium subflavus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 109.) From water. According to Chester (Man. Determ. Bact., 1901, 254), *Bacillus flavescens* Pohl is identical with this species.

Bacillus subgastricus White. (U. S. Dept. Agr. Bur. Ent., Tech. Bul. 14, 1906, 23.) From intestinal contents of honey bee (*Apis mellifera*). While this does not appear to be the same as *Bacillus gastricus* Ford (see Steinhaus, Bacteria Associated Extracellularly with Insects and Ticks. Minneapolis, 1942, 85), it may have been described by some

previous author as White does not indicate that he regards it as new.

Bacillus subochraceus Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 358; *Bacterium subochraceus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 110.) From air.

Bacillus subrubiginosus Migula. (Braunroter Bacillus, Maschek, Bakt. Untersuch. d. Leitmeritzer Trinkwässer, Leitmeritz, 1887; Migula, Syst. d. Bakt., *2*, 1900, 836.) From water.

Bacillus subsulcatus Migula. (*Bacillus aquatilis sulcatus II*, Weichselbaum, Das österreichische Sanitätswesen, 1889, No. 14–23; Migula, Syst. d. Bakt., *2*, 1900, 732.) From water.

Bacillus sulcatus Chester. (*Bacillus sulcatus liquefaciens* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 318; *Bacterium sulcatus liquefaciens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., 9, 1897, 97; Chester, Man. Determ. Bact., 1901, 243; not *Bacillus sulcatus* Migula, Syst. d. Bakt., *2*, 1900, 731.) From water.

Bacillus sulcatus Migula. (*Bacillus aquatilis sulcatus I*, Weichselbaum, Das österreichische Sanitätswesen, 1889, No. 14–23; Migula, Syst. d. Bakt., *2*, 1900, 731.) From water.

Bacillus sulfhydrogenus Miquel. (Ann. de Micrographie, *1*, 1888–1889, 369.) From sewage.

Bacillus tardissimus DeToni and Trevisan. (*Bacillus fluidificans tardissimus* Maggiora, Giorn. Soc. ital. d'Igiene, *11*, 1889, 347; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 967.) From the skin of the human foot.

Bacillus tartricus Grimbert and Fiquet. (Jour. Pharm. et de Chim., 6e Sér., *7*, 1898, 97; Compt. rend. Soc. Biol., *49*, 1897, 962.) Decomposes d-tartrates. Probably identical with *Aerobacter cloacae* (Vaughn et al., Jour. Bact., *52*, 1946, 324).

Bacillus telmatis Trevisan. (*Bacillus saprogenes 2*, Rosenbach, Mikroorganismen bei den Wundinfectionskrankheiten des Menschen, Wiesbaden, 1884; Trevisan, I generi e le specie delle Batteriacee, 1889, 14.) From perspiration of feet.

Bacillus tenuis Doyen. (*Bacillus urinae tenuis* Doyen, Jour. d. connaiss. médic., 1889, 107; Doyen, *ibid.*, 108; not *Bacillus tenuis* Migula, Syst. d. Bakt., *2*, 1900, 587; *Bacillus tenuatus* Trevisan, in DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 948.) From urine.

Bacillus tenuis apis White. (Jour. Path. and Bact., *24*, 1921, 72.) From intestine of bee.

Bacillus terrigenus Frank. (Berichte deutsch. botan. Gesellsch., *4*, 1886, 000.) From soil.

Bacillus thermophilus Miquel. (Miquel, Ann. de Microgr., *1*, 1888–1889, 6; not *Bacillus thermophilus* Chester, Man. Determ. Bact., 1901, 265; not *Bacillus thermophilus* Bergey et al., Manual, 1st ed., 1923, 315.) From water, sewage, soil, etc.

Bacillus theta Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 375; *Bacterium theta* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 144.) From air.

Bacillus tingens Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 10.) From dead larvae of *Orgyia pudibunda*.

Bacillus toluolicum Tausson. (Planta, *7*, 1929, 735.) From soil. Oxidizes toluene.

Bacillus toxigenus Chester. (Bacillus of ice cream poisoning, Vaughn and Perkins, Arch. f. Hyg., *27*, 1896, 308; Chester, Man. Determ. Bact., 1901, 208.) From poisonous ice cream.

Bacillus trambustii Kruse. (Trambusti and Galeotti, Cent. f. Bakt., *11*, 1892, 717; Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 319; *Bacterium trambusti* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 97.) From water.

Bacillus tremaergasius Trevisan. (Bacille du mucus intestinal normal *d*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 153; Trevisan, I generi e le specie delle Batteriacee, 1889, 15.) From normal intestinal mucus.

Bacillus trimethylamin Beijerinck. (Bot. Zeitung, *46*, 1888, 726.)

Bacillus truttae Mersch. (Quoted from Lehmann and Neumann, Bakt. Diag., 7 Aufl., *2*, 1927, 481.) Closely related to *Bacterium salmonicida* Lehmann and Neumann.

Bacillus tumidus Chester. (Anaerobe Bacillus I, Sanfelice, Ztschr. f. Hyg., *14*, 1893, 268; Chester, Man. Determ. Bact., 1901, 265.) From putrefying flesh. Strict anaerobe.

Bacillus uffreduzzii Trevisan. (Batterio della setticemia salivare nei conigli, Bordoni-Uffreduzzi and Di-Mattei, Arch. per le scienze med., *10*, 1886; Trevisan, see DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 951.) From normal human saliva.

Bacillus ulna Cohn. (Beitr. z. Biol. d. Pflanz., *1*, Heft 2, 1872, 177.) From water, air, etc.

Bacillus umbilicatus Zimmermann. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *2*, 1894, 6.) From water.

Bacillus urinae Migula. (Ein Harnbacterium, Karplus, Arch. f. path. Anat., *131*, 1893, 211; Migula, Syst. d. Bakt., *2*, 1900, 739.) From urine.

Bacillus utpadeli Trevisan. (Bacillus aus Zwischendeckenfüllung, Utpadel, Arch. f. Hyg., *6*, 1887, 359; Trevisan, I generi e le specie delle Batteriacee, 1889, 15.) From the intestine.

Bacillus vacuolatus Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 357; *Bacterium vacuolatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 81.) From a trap of the carnivorous water plant, *Utricularia vulgaris*.

Bacillus vegetus Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 399.) From the stomach and intestines of birds.

Bacillus velox Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 405.) From the stomach and intestines of birds.

Bacillus venenosus brevis Vaughan. (Amer. Jour. Med. Sci., *104*, 1892, 192; *Bacterium venenosus* and *Bacterium venenosus brevis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 76.) From water.

Bacillus venenosus Chester. (*Bacillus venenosus invisibilis* Vaughan, Amer. Jour. Med. Sci., *104*, 1892, 192; *Bacterium venenosus invisibilis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 76; Chester, Man. Determ. Bact., 1901, 224; not *Bacillus venenosus* Vaughan, Amer. Jour. Med. Sci., *104*, 1892, 191.) From water.

Bacillus venenosus liquefaciens Vaughan. (Amer. Jour. Med. Sci., *104*, 1892, 193.) From water.

Bacillus ventricosus Weiss. (Weiss, Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 233; not *Bacillus ventricosus* Bredemann and Heigener, Cent. f. Bakt., II Abt., *93*, 1935, 102.) From vegetable infusions.

Bacillus ventriculi Raczynski. (Diss. milit. medic. Acad. Petropolitanae Ruteniae, 1888; abst. in Cent. f. Bakt., *6*, 1889, 113.) From the stomach of a dog.

Bacillus vermiculosus Zimmermann. (Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 40; *Bacterium vermiculosus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 99.) From water.

Bacillus versatilis DeToni and Trevisan. (*Bacillus A*, Maggiora, Giorn. Soc. ital. d'Igiene, *11*, 1889, 339; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 968.) From the skin of the human foot and from air.

Bacillus vesiculiferus Migula. (*Bacillus strumitis β*, Tavel, Ueber die Aetiologie der Strumitis, 1892, 110; Migula, Syst. d. Bakt., *2*, 1900, 741.) From a case of strumitis.

Bacillus vialis Hansgirg. (Oesterr. bot. Ztschr., 1888, 6.) From roadside soil from near Prague.

Bacillus viator Trevisan. (Bacille de l'air *e*, Babes, in Cornil and Babes, Les Bactéries, 2nd ed., 1886, 150; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From air.

Bacillus villosus Migula. (*Bacillus aquatilis villosus* Tataroff, Inaug. Diss.,

Dorpat, 1891, 47; Migula, Syst. d. Bakt., *2*, 1900, 828; not *Bacillus villosus* Keck, Inaug. Diss., Dorpat, 1890, 47.) From water.

Bacillus vinicola Migula. (*Bacillus saprogenes vini II*, Kramer, Die Bakterien in ihren Beziehungen zur Landwirtschaft, *2*, 1892, 136; Migula, Syst. d. Bakt., *2*, 1900, 685.) From wine.

Bacillus viniperda Migula. (*Bacillus saprogenes vini I*, Kramer, Die Bakterien in ihren Beziehungen zur Landwirtschaft, *2*, 1892, 135; Migula, Syst. d. Bakt., *2*, 1900, 684.) From wine.

Bacillus virens van Tieghem. (Bull. Soc. bot. France, *27*, 1880, 175.) From aquatic plants.

Bacillus viridans Zimmermann. (Bakt. unserer Trink. u. Nutzwässer, Chemnitz, *2*, 1894, 22.) From water.

Bacillus viridescens non-liquefaciens Ravenel. (Ravenel, Mem. Nat. Acad. Sci., *8*, 1896, 14; *Bacterium viridescens non-liquefaciens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 72 and 123.) From soil.

Bacillus vulpinus von Iterson. (Cent. f. Bakt., II Abt., *12*, 1904, 111.) From fresh garden soil, canal water.

Bacillus wardii Chester. (Gas- and taint-producing bacillus in cheese curd, Moore and Ward, Cornell Univ. Agr. Expt. Sta., Bull. 158, 1899, 221–227; Chester, Man. Determ. Bact., 1901, 206.) From tainted, gassy cheese curd and from milk drawn directly from the udder. Presumably this was a coliform organism.

Bacillus weckeri Trevisan. (Bacillus der Jequirity-Ophthalmie, de Wecker, 1882; see Flügge, Die Mikroorganismen, 2 Aufl., 1886, 279; Trevisan, I generi e le specie delle Batteriacee, 1889, 17.) From infusions of jequirity seed (*Abri precatorii*).

Bacillus wesenbergii Chester. (Bacillus der Fleischvergiftung, Wesenberg, Ztschr. f. Hyg., *28*, 1898, 484; Chester, Man. Determ. Bact., 1901, 247; not *Bacillus wesenberg* Castellani.) From meat which caused a meat poisoning outbreak. Closely related to *Proteus vulgaris* Hauser.

Bacillus wichmanni Trevisan. (Goldgelber Wasserbacillus, Adametz and Wichmann, Mitth. Oest. Vers. Stat. f. Brauerei u. Mälz., *1*, 1888, 49; Trevisan, I generi e le specie delle Batteriacee, 1889, 19; *Bacillus chryseus* Migula, Syst. d. Bakt., *2*, 1900, 833.) From water.

Bacillus zeta Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 369; *Bacterium zeta* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 114.) From air.

Bacillus zonatus Migula. (Bacillus No. 15, Pansini, Arch. f. path. Anat., *122*, 1890, 450; Migula, Syst. d. Bakt., *2*, 1900, 658.) From sputum.

Bacillus zörkendörferi Migula. (*Bacillus oogenes hydrosulfureus γ*, Zörkendörfer, Arch. f. Hyg., *16*, 1893, 385; Migula, Syst. d. Bakt., *2*, 1900, 696.) From hens' eggs.

Bacillus zymoseus (Leube) Trevisan. (*Coccobacillus zymogenes* Leube, Arch. f. path. Anat., 1885; Trevisan, I generi e le specie delle Batteriacee, 1889, 16.) From fermenting infusions.

Bacterium acidi propionici Weigmann. (Weigmann, quoted from Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 76; *Plocamobacterium acidi propionici* Pribram, *idem*.)

Bacterium aeris Migula. (*Bacillus aeris minutissimus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 441; *Bacterium aeris minutissimus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 109; Migula, Syst. d. Bakt., *2*, 1900, 445; *Bacterium aeris-minutissimum* Chester, Man. Determ. Bact., 1901, 168.) From air.

Bacterium aerogenes I and *II* Miller. (Miller, Deutsche med. Wochnschr., *12*, 1886, 119; see Miller, Die Mikroorganismen der Mundhöhle, Leipzig, 1889, 261 and 262; not *Bacterium aerogenes* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 53; *Bacillus millerianus* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 952.) From the digestive tract of man.

Bacterium agreste Löhnis. (Löhnis, Cent. f. Bakt., I Abt., Orig., *40*, 1906, 177; *Bacillus agrestis* de Rossi, Microbiol. agraria e technica, Torino, 1927, 828; not *Bacillus agrestis* Werner, Cent. f. Bakt., II Abt., *87*, 1933, 468.) From soil.

Bacterium agrigenum (Trevisan) Migula. (*Bacillus septicus agrigenus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 257; *Pasteurella agrigena* Trevisan, I generi e le specie delle Batteriacee, 1889, 21; *Bacterium septicus agrigenus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 85; Migula, Syst. d. Bakt., *2*, 1900, 372; *Bacterium septicum* Chester, Man. Determ. Bact., 1901, 143.) From soil.

Bacterium album Migula. (Weisser Bacillus, Tataroff, Inaug. Diss., Dorpat, 1891, 35; Migula, Syst. d. Bakt., *2*, 1900, 419.) From water.

Bacterium algeriense Migula. (Gayon and Dubourg, Ann. Inst. Past., *8*, 1894, 108; Migula, Syst. d. Bakt., *2*, 1900, 513.) Isolated in Algiers from wine where it causes a mannitol fermentation.

Bacterium aliphaticum Tausz and Peter. (Cent. f. Bakt., II Abt., *49*, 1919, 505.) From garden soil.

Bacterium aliphaticum liquefaciens Tausz and Peter. (Cent. f. Bakt., II Abt., *49*, 1919, 505.) From garden soil.

Bacterium allantoides (Klein) Chester. (*Bacillus allantoides* Klein, Cent. f. Bakt., *6*, 1889, 383; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 103.) Isolated as a culture contamination.

Bacterium alutaceum Migula. (Goldgelber chagrinierter Bacillus, Tataroff, Inaug. Diss., Dorpat, 1891, 62; Migula, Syst. d. Bakt., *2*, 1900, 464.) From water.

Bacterium ambiguum Chester. (Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *11*, 1900, 59; not *Bacterium ambiguus* Chester, *ibid.*, *9*, 1897, 71; not *Bacterium ambiguum* Levine, Abst. Bact., *4*, 1920, 15.) From soil.

Bacterium amforeti Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian), Petrograd, 1914, 237.) From sea water.

Bacterium anaerobium Migula. (Fuchs, Inaug. Diss., Greifswald, 1890; Migula, Syst. d. Bakt., *2*, 1900, 388.) Obligate anaerobe. Pyogenic. Possibly a spore-former.

Bacterium anguillarum (Canestrini) Migula. (*Bacillus anguillarum* Canestrini, Atti d. R. Instituto Veneto di Scienze, Ser. 7, 1892–93; Migula, Syst. d. Bakt., *2*, 1900, 442.) From diseased eels in the valleys of Comacchio.

Bacterium angustum Migula. (Lembke, Arch. f. Hyg., *26*, 1896, 305; Migula, Syst. d. Bakt., *2*, 1900, 474.) From feces.

Bacterium aphthosum (Kruse) Chester. (Bacillus der Mundseuche des Menschen, Siegel, Deutsch. med. Wochnschr., 1891, No. 49, 1328; *Bacillus aphthosus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 427; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 85.) From the liver and kidneys of cattle affected with foot and mouth disease.

Bacterium apis No. 1, No. 2 and No. 3, Metalnikov and Kostritsky. (Compt. rend. Soc. Biol., Paris, *114*, 1933, 1291.) From diseased bees (*Apis mellifera.*)

Bacterium aquatile aurantiacum von Rigler. (Hyg. Rund., *12*, 1902, 480.) From bottled mineral waters.

Bacterium aquatile citreum von Rigler. (Hyg. Rund., *12*, 1902, 481.) From bottled mineral waters.

Bacterium aquatile debile von Rigler. (Hyg. Rund., *12*, 1902, 481.) From bottled mineral waters.

Bacterium aquatile flavum von Rigler. (Hyg. Rund., *12*, 1902, 480.) From bottled mineral waters.

Bacterium aquatile luteum von Rigler. (Hyg. Rund., *12*, 1902, 480.) From bottled mineral waters.

Bacterium arborescens non liquefaciens von Rigler. (Hyg. Rund., *12*, 1902, 479; not *Bacterium arborescens non-liquefaciens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 103.) From bottled mineral waters.

Bacterium arcticum Issatchenko. (Re-

cherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 148.) From sea water.

Bacterium arthritidis Migula. (Schüller, Berliner klin. Wochnschr., 1893, No. 36; *Bacillus arthritidis chronicae* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 287; Migula, Syst. d. Bakt., *2*, 1900, 443.) From a case of chronic arthritis.

Bacterium asporiferum Migula. (Flügge, Ztschr. f. Hyg., *17*, 1894, 290; Anaërobier No. II, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 251; Migula, Syst. d. Bakt., *2*, 1900, 446.) From milk.

Bacterium aurantii (Viron) Migula. (*Bacillus aurantii* Viron, Compt. rend. Acad. Sci., Paris, 114, 1892, 179; Migula, Syst. d. Bakt., *2*, 1900, 512.)

Bacterium aurantium-roseum Honing. (Honing, Cent. f. Bakt., II Abt., *37*, 1913, 373; *Plocamobacterium aurantium* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 77.) From fermenting tobacco.

Bacterium aurescens (Frankland and Frankland) Migula. (*Bacillus aurescens* Frankland and Frankland, Philos. Trans. Royal Soc. of London, *178*, 1887, B, 271; not *Bacillus aurescens* Ravenel, Mem. Nat. Acad. Sci., *8*, 1896, 8; Migula, Syst. d. Bakt., *2*, 1900, 466.) From air.

Bacterium aureum (Frankland and Frankland) Migula. (*Bacillus aureus* Frankland and Frankland, Philos. Trans. Royal Soc. of London, *178*, 1887, B, 272; Migula, Syst. d. Bakt., *2*, 1900, 480.) From air.

Bacterium aureum (Adametz) Chester. (*Bacillus aureus* Adametz, quoted from Sternberg, Man. of Bact., 1893, 621; not *Bacillus aureus* Frankland and Frankland, Philos. Trans. Roy. Soc. London, *178*, 1887, B, 272; not *Bacillus aureus* Pansini, Arch. f. path. Anat., *122*, 1890, 436; *Bacillus aureo-flavus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 310; *Bacterium aureo flavus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 109; Chester, *ibid.*, 129; not *Bacterium aureum* Migula, Syst. d. Bakt., *2*, 1900, 480; *Bacillus flavus* Chester, Man. Determ. Bact., 1901, 255; not *Bacillus flavus* Fuhrmann, Cent. f. Bakt., II Abt., *19*, 1907, 117; not *Bacillus flavus* Bergey et al., Manual, 1st ed., 1923, 286.) From water (Adametz); from the skin in cases of eczema (Tommasoli, Monats. f. prakt. Dermatol., *9*.)

Bacterium avium Chester. (Bacillus of roup in fowls, Moore, U. S. Dept. Agr. Bur. Animal Industry, Bull. 8, 1895; Chester, Man. Determ. Bact., 1901, 138.) From exudate of fowls in roup or diphtheria.

Bacterium babesii Migula. (*Bacillus septicus acuminatus* Babes, Bakteriologische Untersuchungen der septischen Prozesse des Kindesalters, Leipzig, 1889; see Eisenberg, Bakt. Diag., 3 Aufl., 1891, 327; *Bacterium septicus acuminatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 66; Migula, Syst. d. Bakt., *2*, 1900, 507; *Bacterium acuminatum* Chester, Man. Determ. Bact., 1901, 119.) From blood and organs of a new-born infant with septicemia.

Bacterium balbianii Billet. (Billet, Compt. rend. Acad. Sci., Paris, *107*, 1888, 423; also in Bull. Sci. de la France et de la Belgique, *21*, 1890, 108; *Bacillus balbianii* Trevisan, I generi e le specie delle Batteriacee, 1889, 17.) From sea water.

Bacterium barentsianum Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 155.) From sea water.

Bacterium beijerincki Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 157.) From sea water.

Bacterium benzoli a and *b* Wagner. (Ztschr. f. Garungphysiol., *4*, 1914, 289.) From soil. Utilize benzene and certain benzene derivatives.

Bacterium besseri Migula. (Besser, Cent. f. Bakt., *13*, 1893, 590; Migula, Syst. d. Bakt., *2*, 1900, 508.) From smallpox.

Bacterium betae viscosum Panek. (Bull. Acad. Sci. Cracovie, *1*, 1905, 5.)

From fermenting beets. Reported to liquefy agar-gelatin (Biernacki, Cent. f. Bakt., *29*, 1911, 166). Stanier (Jour. Bact., *42*, 1941, 548) thinks this was a heterofermentative *Lactobacillus*.

Bacterium bossonis Chester. (Bacillus über eine neue Infektionskrank. des Rindviehs, Bosso, Cent. f. Bakt., *22*, 1897, 537 and *23*, 1898, 318; Chester, Man. Determ. Bact., 1901, 153.) Associated with an infectious disease of cattle.

Bacterium boutrouxii (Trevisan) De-Toni and Trevisan. (Micrococcus capable d'acétifier l'alcohol, Boutroux, Ann. Inst. Past., *2*, 1888, 209; *Bacillus boutrouxii* Trevisan, I generi e le specie delle Batteriacee, 1889, 16; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1021.) From alcoholic infusions.

Bacterium bovis Migula. (*Pneumobacillus liquefaciens bovis* Arloing, Compt. rend. Acad. Sci., Paris, *99*, 18—, 109 and 116; *Bacillus pneumonicus liquefaciens* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 288; *Bacterium pneumonicus liquefaciens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 99; Migula, Syst. d. Bakt., *2*, 1900, 442; *Bacterium pneumonicum* Chester, Man. Determ. Bact., 1901, 158.) From the exudate of lung plague in cattle. A Gram-positive coccus-like bacterium.

Bacterium brassicae Conrad. (*Bacterium brassicae acidae* Lehmann and Conrad, in Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 232; Conrad, Arch. f. Hyg., *29*, 1897, 82; not *Bacterium brassicae* Wehmer, Cent. f. Bakt., II Abt., *10*, 1903, 628; not *Bacterium brassicae* Migula, Syst. d. Bakt., *2*, 1900, 296 (*Bacillus brassicae* Pommer, Mitt. botan. Inst. Graz, *1*, 1886, 95); *Bacillus brassicae* Migula, *loc. cit.*, 737.) From sauerkraut.

Bacterium breitfussi Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 152.) From sea water.

Bacterium brevissimum Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 227.) From vegetable infusions.

Bacterium brunneoflavum (Dyar) Chester. (*Bacillus brunneoflavus* Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 362; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 112.) Culture received from Kràl's laboratory as *Micrococcus brunneus*.

Bacterium bullosum Migula. (Bacillus No. 18, Pansini, Arch. f. pathol. Anat. u. Physiol., *122*, 1890, 451; Migula, Syst. d. Bakt., *2*, 1900, 415.) From feces.

Bacterium cadaveris (Sternberg) Chester. (*Bacillus cadaveris* Sternberg, Man. of Bact., 1893, 492; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 126.) From liver and kidneys of yellow fever cadavers. Anaerobe.

Bacterium canalis Migula. (Kapseltragender Kanalbacillus, Mori, Ztschr. f. Hyg., *4*, 1888, 52; *Bacillus canalis capsulatus* Sternberg, Man. of Bact., 1893, 476; *Bacterium canalis capsulatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 130; Migula, Syst. d. Bakt., *2*, 1900, 351.) From sewage.

Bacterium canalis parvum (Sternberg) Chester. (*Bacillus canalis parvus* Sternberg, Man. of Bact., 1893, 476; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 130.) Obtained by Mori (1888) from sewage.

Bacterium carneum (Kruse) Chester. (Fleischfarbiger Bacillus, Tils, Ztschr. f. Hyg., *9*, 1890, 294; *Bacillus carnicolor* Frankland and Frankland, Microorganisms of Water, 1894, 477; *Bacillus carneus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 304; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 113.) From water.

Bacterium carnosum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 448.) From the intestines of birds.

Bacterium cartilagineum (Olsen-Sopp) Buchanan and Hammer. (*Bacillus cartilagineus* Olsen-Sopp, Cent. f. Bakt., II Abt., *33*, 1912, 49; Buchanan and Hammer, Iowa Sta. Agr. Exp. Sta., Res. Bull. 22, 1915, 271.) From slimy or ropy sour milk called false taette.

Bacterium caseicola Migula. (Bacillus No. XII, Adametz, Landw. Jahrb., *18*, 1889, 245; Migula, Syst. d. Bakt., *2*, 1900, 475.) From cheese.

Bacterium castellum Henrici. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 38.) From cheese.

Bacterium catenula Dujardin. (Dujardin, Hist. natur. des zooph., 1841; *Bacillus catenula* Trevisan, I generi e le specie delle Batteriacee, 1889, 18; not *Bacillus catenula* Migula, Syst. d. Bakt., *2*, 1900, 588.) From rice paddies and swamps.

Bacterium cavatum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 449.) From the intestines of birds.

Bacterium cavernae Migula. (*Bacillus cavernae minutissimus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 440; Pfeiffer und Beck, Deutsch. med. Wochnschr., 1892, No. 21; Migula, Syst. d. Bakt., *2*, 1900, 509.) From human tuberculosis.

Bacterium caviae fortuitum (Sternberg) Chester. (*Bacillus caviae fortuitus* Sternberg, Man. of Bact., 1893, 650; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 74.) From the liver of a yellow fever cadaver.

Bacterium cavicida havaniensis (Sternberg) Chester. (*Bacillus cavicida havaniensis* Sternberg, Man. of Bact., 1893, 425; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 74.) From the intestine of a yellow fever cadaver.

Bacterium centricum Migula. (Huber, Armin, Arch. f. pathol. Anat. u. Physiol., *134*, 1893, 216; Migula, Syst. d. Bakt., *2*, 1900, 390; not *Bacterium concentricum*, a typographical error, see Migula, *ibid.*, page v.) From a case of cystitis.

Bacterium cerinum Henrici. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 50.) From cheese.

Bacterium chlorinum Engelmann. (Bot. Zeitung, 1882, 324.) Green pigment.

Bacterium chologenes (Kruse) Chester. (Colonbacillus, Stern, Deutsche med. Wochnschr., 1893, 613; *Bacillus chologenes* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 374; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 69.) From a case of purulent meningitis.

Bacterium chryseum Migula. (Bacillus nova species II, Freund, Inaug. Diss., Erlangen, 1893, 37; Migula, Syst. d. Bakt., *2*, 1900, 477.) Chromogenic bacterium from the mouth cavity.

Bacterium chrysogloea Zopf. (Zopf, in Overbeck, Nova Acta d. kais. Leop.-Carol. Akad. d. Naturf., *55*, 1891, No. 7; *Bacillus chrysogloia* (sic) Zimmermann, Bakt. unserer Trink- u. Nutzwässer, *2*, 1894, 12.) From water.

Bacterium citreum (Frankland and Frankland) Migula. (*Bacillus citreus* Frankland and Frankland, Philos. Trans. Royal Soc. of London, *178*, 1887, B, 272; Migula, Syst. d. Bakt., *2*, 1900, 459.) From air.

Bacterium coli apium Serbinow. (Jour. Microbiol. Petrograd., *2*, 1915, 19.) From honey bees (*Apis mellifera*).

Bacterium coli similis (Sternberg) Chester. (*Bacillus coli similis* Sternberg, Man. of Bact., 1893, 650; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 132.) From a human liver.

Bacterium colloideum Migula. (*Bacterium butyri colloideum* Lafar, Arch. f. Hyg., *13*, 1891, 17; Migula, Syst. d. Bakt., *2*, 1900, 409.) From butter.

Bacterium comes Bersteyn. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 93.) From soil.

Bacterium compactum (Kruse) Migula. (*Bacillus compactus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 353; Migula, Syst. d. Bakt., *2*, 1900, 438.) From air.

Bacterium concentricum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 437.) From the intestines of birds.

Bacterium conjunctivitidis (Kruse) Migula. (Koch, Berichte aus Aegypten an den preuss. Staatsminister des Innern; see Arb. a. d. kaiserl. Gesundheitsamte, *3*, 1887; Kartulis, Cent. f. Bakt., *1*, 1887, 289; *Bacillus aegyptius*

Trevisan, I generi e le specie delle Batteriacee, 1889, 13; *Bacillus conjunctivitidis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 440; *Bacterium conjunctivitis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 67; Migula, Syst. d. Bakt., *2*, 1900, 509; not *Bacterium conjunctivitidis* Chester, Man. Determ. Bact., 1901, 120; *Bacterium aegyptium* Chester, *ibid.*, 121.) Associated with conjunctival catarrh in Egypt.

Bacterium corticale (Haenlein) Migula. (*Bacillus corticalis* Haenlein, Deutsch. Gerberzeitung, 1894, No. 18–34; Migula, Syst. d. Bakt., *2*, 1900, 449.) Found on pine bark; in acid dyeing-liquor.

Bacterium crenatum Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 221.) From fermenting malt.

Bacterium cristalliferum Gicklhorn. (Cent. f. Bakt., II Abt., *50*, 1920, 420.) A sulfur bacterium from soil. See Manual, 5th ed., 1939, 86 for a description of this organism.

Bacterium cuticularis (Tils) Chester. (*Bacillus cuticularis* Tils, Ztschr. f. Hyg., *9*, 1890, 293; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 105.) From water.

Bacterium debile Berstyn. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 96.) From soil.

Bacterium delendae-muscae Roubaud and Descazeaux. (Compt. rend. Acad. Sci., Paris, *177*, 1923, 716.) From fly larvae (*Stomoxys calcitrans* and *Musca domestica*).

Bacterium deliense Honing. (Cent. f. Bakt., II Abt., *37*, 1913, 377.) From tobacco plants in Sumatra.

Bacterium diatrypeticum Migula. (*Bacillus diatrypeticus casei* Baumann, Landwirtsch. Versuchsstationen, *42*, 1893, 181; Migula, Syst. d. Bakt., *2*, 1900, 404.) From cheese.

Bacterium enchelys Ehrenberg. (Ehrenberg, Abhandl. d. Akad. d. Wissensch. zu Berlin, 1830, 61; *Bacillus enchelys* Trevisan, I generi e le specie delle Batteriacee, 1889, 18.) From water.

Bacterium endocarditidis Migula. (*Bacillus endocarditidis capsulatus* Weichselbaum, Beitr. z. pathol. Anat. u. z. allgem. Pathol., *4*, 1887, 197; Migula, Syst. d. Bakt., *2*, 1900, 359.) Found in the aorta, the left ventricle, the spleen and kidneys of cadavers.

Bacterium endometritidis (Kruse) Chester. (*Bacillus endometritidis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 432; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 88.) From a liver abscess.

Bacterium endometritis canis Meyer. (Meyer, quoted from Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 77; *Plocamobacterium endometritis* Pribram, *idem.*) From a case of endometritis in a dog.

Bacterium enterocoliticum Schleifstein and Coleman. (A motile, Gram-negative bacillus, Schleifstein and Coleman, N. Y. State Jour. Med., *39*, 1939, 1749; Ann. Rept. Div. Lab. and Res., N. Y. State Dept. Health for 1943, 56.) From lesions about the face, from an ulcer in the intestine and from the intestinal contents. Resembles *Bacillus lignieri* and *Pasteurella pseudotuberculosis*.

Bacterium erythromyxa (Zopf) Migula. (*Micrococcus* (*Staphylococcus*) *erythromyxa* Zopf, Ber. d. deutschen bot. Gesellsch., 1891, 22; *Rhodococcus erythromyxa* Zopf, *loc. cit.*; Migula, Syst. d. Bakt., *2*, 1900, 487; *Bacillus erythromyxa* Matzuschita, Bakt. Diag., 1902, 389.) Frequently listed as a *Micrococcus*.

Bacterium exanthematicum (Kruse) Chester. (Bacille, Babes and Oprescu, Ann. Inst. Past., *5*, 1891, 273; *Bacillus exanthematicus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 426; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 87.) From a case of hemorrhagic septicemia.

Bacterium fausseki Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 157.) From sea water.

Bacterium ferophilum (sic) Migula.

(Die ferrophilen Bakterien, Marpmann, Cent. f. Bakt., II Abt., *4*, 1898, 21; Migula, Syst. d. Bakt., *2*, 1900, 455 and 1058.) Isolated during studies on black discoloration of cheese.

Bacterium finitimum Chester. (*Bacillus finitimus ruber* Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 361; *Bacterium finitimus ruber* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 116; Chester, Man. Determ. Bact., 1901, 177.) From air.

Bakterium flaveum Wilhelmy. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 15.) From meat extract.

Bacterium flavocoriaceum (Eisenberg) Chester. (Schwefelgelber Bacillus, Adametz and Wichmann, Die Bakterien der Trink- und Nutzwässer, Mitt. Oest. Versuchsstat. f. Brauerei u. Mälz., Wien, Heft 1, 1888, 49; *Bacillus flavocoriaceus* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 144; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 112.) From water.

Bacterium flavofuscum Migula. (No. 9, Lembke, Arch. f. Hyg., *26*, 1896, 304; Migula, Syst. d. Bakt., *2*, 1900, 479.) From meat.

Bacterium flavum Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 151.) From sea water.

Bacterium foliicola (Miehe) de Jongh. (*Bacillus foliicola* Miehe, see Jahrb. wiss. Bot., *53*, 1914, 1; *ibid.*, *58*, 1919, 29; de Jongh, On the Symbiosis of *Ardisia crispa*. Thesis, Univ. Leiden, 1938, 33.) A bacterial symbiont isolated from germinating seeds and embryos.

Bacterium freundii Migula. (Bacillus nova species I, Freund, Inaug. Diss., Erlangen, 1893, 31; Migula, Syst. d. Bakt., *2*, 1900, 472.) From the mouth cavity.

Bacterium fungoides (Tschistowitsch) Migula. (*Bacillus fungoides* Tschistowitsch, Berl. klin. Wochnschr., 1892, 513; Migula, Syst. d. Bakt., *2*, 1900, 391.) From pus.

Bacterium fuscum (Flügge) Migula. (*Bacillus fuscus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 290; Migula, Syst. d. Bakt., *2*, 1900, 463.) From water.

Bacterium gamma (Dyar) Chester. (*Bacillus gamma* Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 367; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 106.) From air.

Bacterium gammari Vejdovsky. (Cent. f. Bakt., II Abt., *11*, 1904, 484.) From sections of a fresh water crustacean (*Gammarus zschokkei*). Cells exhibit nuclei, showing mitosis.

Bacterium gelechiae No. 1 and No. 2, Metalnikov and Metalnikov. (Compt. rend. Acad. Agr., France, *18*, 1932, 204.) From dead and dying larvae of a moth (*Gelechia gossypiella*).

Bacterium gelechiae No. 5, Metalnikov and Meng. (Compt. rend. Soc. Biol., Paris, *113*, 1933, 170.) From dead larvae of a moth (*Gelechia gossypiella*).

Bacterium gemmiforme Migula. (Lembke, Arch. f. Hyg., *29*, 1897, 313; Migula, Syst. d. Bakt., *2*, 1900, 391.) From intestinal contents.

Bacterium gibbosum Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 230.) From fermenting beets and malt.

Bacterium gingivae pyogenes Miller. (Miller, Die Mikroorganismen der Mundhöhle, Leipzig, 1888, 217; *Bacillus gingivae pyogenes* Sternberg, Manual of Bact., 1893, 471.) From an alveolar abscess.

Bacterium gingivitidis (Kruse) Migula. (Babes, Deutsch. med. Wochnschr., 1893, 1035; *Bacillus gingivitidis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 427; Migula, Syst. d. Bakt., *2*, 1900, 393.) Isolated in an epidemic of scurvy in Jassy.

Bacterium gliscrogenum Malerba and Sanna-Salaris. (Malerba and Sanna-Salaris, Lavori eseguiti nell'Istituto fisiol. di Napoli, *2*, 1888, 13 and 95; *Bacillus gliscrogenus* Trevisan, I generi e le specie delle Batteriacee, 1889, 14.) From urine.

Bacterium gonnermanni Migula. (*Bacillus tuberigenus 6* Gonnermann, Land-

wirtsch. Jahrb., *23*, 1894, 657; Migula, Syst. d. Bakt., *2*, 1900, 418.) From root nodules of lupine.

Bacterium gracilescens Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 259.) From fermenting asparagus and malt.

Bacterium gracillimum Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 235.) From bean and asparagus infusions.

Bacterium granulatum Henrici. (Henrici, Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 33; not *Bacterium granulatum* Chester, Man. Determ. Bact., 1901, 189.) From cheese.

Bacterium granulosum Weiss. (Weiss, Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 212; not *Bacterium granulosum* Lehmann and Neumann, Bakt. Diag., 5 Aufl., *2*, 1912, 306.) From vegetable infusions.

Bacterium gryllotalpae Metalnikov and Meng. (Compt. rend. Acad. Sci., Paris, *201*, 1935, 367.) From diseased larvae of the cricket (*Gryllotalpa gryllotalpa*).

Bacterium gummosum Ritsert. (Ritsert, Ber. d. pharmaz. Gesell., *1*, 1891, 389; abst. in Cent. f. Bakt., *11*, 1892, 730; *Bacillus gummosus* Migula, Syst. d. Bakt., *2*, 1900, 873.) A mixture of a spore-forming rod and a streptococcus. See *Bacillus gummosus* Happ and *Micrococcus gummosus* Happ.

Bacterium halans (Zimmermann) Migula. (*Bacillus halans* Zimmermann, Die Bakterien unserer Trink- u. Nutzwässer, Chemnitz, *2*, 1894, 54; Migula, Syst. d. Bakt., *2*, 1900, 429.) From water.

Bacterium hebetisiccus Steinhaus. (Jour. Bact., *42*, 1941, 762 and 773.) From the walking stick (*Diapheromera femorata*).

Bacterium herbicola α aureum Geilinger. (Mitteil. a. d. Gebiete d. Lebensmitteluntersuchungen u. Hyg., *12*, 1921, 262.) From corn meal. This is a variety of *Bacillus herbicola* Burri and Düggeli.

Bacterium herbicola rubrum Düggeli. (Düggeli, Cent. f. Bakt., II Abt., *12*, 1904, 605; *Bacterium herbicola β rubrum* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 356.) From germinating plants, roots and barley seeds.

Bacterium hexacarbovorum Störmer. (Jahresber. d. Vereinigg. f. angew. Botanik, *5*, 1907, 116.) From soil. Utilizes benzene and certain benzene derivatives.

Bacterium hidium Goobin. (Russian Health Resort Service, *5*, 1923, 3.) Attacks ethane and other hydrocarbons.

Bacterium hirudinicolicum Lehmensick. (Cent. f. Bakt., I Abt., Orig., *147*, 1941, 317; see Biol. Abst., *18*, 1944, No. 6761.) Symbiotic in the intestines of *Hirudo officinalis* and *H. medicinalis*.

Bacterium hoshigaki var. *glucuronicum II* and *III* Takahashi and Asai. (Cent. f. Bakt., II Abt., *87*, 1933, 395 and 405.) From dried persimmons (hoshigaki).

Bacterium infecundum Chester. (*Bacillus filiformis havaniensis* Sternberg, Man. of Bact., 1893, 650; *Bacterium filiformis havaniensis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 126; Chester, Man. Determ. Bact., 1901, 184.) From the liver of a yellow fever cadaver. Anaerobic.

Bacterium inocuum Chester. (Wilde, Wien. klin. Wochnschr., 1892, No. 1–2; *Bacillus lactis inocuus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 352; *Bacterium lactis inocuus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 82; Chester, Man. Determ. Bact., 1901, 138.) From milk.

Bacterium intrinsectum Steinhaus. (Jour. Bact., *42*, 1941, 764 and 774.) From an unidentified leaf beetle.

Bacterium iogenum Baumgartner. (Deutsche Monatschr. f. Zahnheilk., *27*, 764; *Bacterium jogenum* Baumgartner, Ergeb. d. gesam. Zahnheilk., *1*, 1911, 752 and 779; *B. iogenum* Kligler, Jour. Allied Dent. Soc., *10*, 1915, 152.) From the mouth. Regarded as identical with *Jodococcus vaginatus* Miller by Kligler (*loc. cit.*).

Bacterium keratomalaciae Migula. (*Bacillus septicus keratomalaciae* Babes,

Bakteriol. Untersuch. d. sept. Prozesse d. Kindesalters, Leipzig, 1889; Migula, Syst. d. Bakt., *2*, 1900, 363.) From an infected cornea.

Bacterium knipowitchi Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 150.) From sea water. A phosphorescent bacterium found to be pathogenic for the mealworm (*Tenebrio molitor*) by Pfeiffer and Stammer (Ztschr. f. Morph. u. Ökol. d. Tiere, *20*, 1930, 157).

Bacterium kralii (Dyar) Chester. (*Bacillus kralii* Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 376; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 93; not *Bacterium kralii* Chester, Man. Determ. Bact., 1901, 166.) Received as *Bacillus butyricus* from Kràl's laboratory by Dyar. The 1900 Kràl Catalogue lists cultures of *Bacillus butyricus* Botkin and *Bacillus butyricus* Hueppe. As Dyar found that the characters of his culture differed from those of *Bacillus butyricus* Hueppe, Dyar's culture was probably *Bacillus butyricus* Botkin.

Bacterium kralii Chester. (*Bacillus fuscus liquefaciens* Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 375; *Bacterium fuscus liquefaciens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 108; Chester, Man. Determ. Bact., 1901, 166.) Received as *Bacillus fuscus* from Kràl's laboratory by Dyar who also found it in air. The 1920 Kràl catalogue lists *Bacillus fuscus* Flügge syn. *Bacterium brunneum* Schrötter (sic); braunrother Bacillus Maschek.

Bacterium laerii Migula. (*Bacillus viscosus No. 1*, van Laer, Extrait des mémoires couronnés et autres mémoires, Acad. Royale de Belgique, 1889, 36; see Kramer, Bakteriol. in ihren Beziehungen zur Landwirtsch., *2*, 1892, 119; *Bacillus viscosus cerevisiae* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 359; *Bacterium viscosus cerevisiae* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 78; Migula, Syst. d. Bakt., *2*, 1900, 402; *Bacterium viscosum* Chester, Man. Determ. Bact., 1901, 128.) From beer, yeast, air, bread. Causes a slimy fermentation.

Bacterium laevolacticum Migula. (*Bacillus acidi laevolactici* Schardinger, Monatsh. f. Chemie, *11*, 1890, 544; Migula, Syst. d. Bakt., *2*, 1900, 406; *Bacterium acidi laevolactici* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 178.) From milk.

Bacterium laminariae Billet. (Compt. rend. Acad. Sci., Paris, *106*, 1888, 293; *Billetia laminariae* Trevisan, I generi e le specie delle Batteriacee, 1889, 11; *Kurthia laminariae* De Toni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 931.) From rotting sea weed. The type species of the genus *Billetia* Trevisan.

Bacterium langkatense Honing. (Cent. f. Bakt., II Abt., *37*, 1913, 381.) From tobacco plants in Sumatra.

Bacterium largum (v. Klecki) Migula. (*Bacillus largus* v. Klecki, Ann. Inst. Past., *9*, 1898, 728; Migula, Syst. d. Bakt., *2*, 1900, 448.) From the intestines of dogs.

Bacterium lepierrei Chester. (Bacille fluorescent pathogène, Lepierre, Ann. Inst. Past., *9*, 1895, 643; Chester, Man. Determ. Bact., 1901, 182.) From cistern water.

Bacterium lethalis (Babes) Chester. (*Proteus lethalis* Babes, Progrès Médical Roumain, 1889; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 104; *Bacillus lethalis* Chester, Man. Determ. Bact., 1901, 249.) From lung gangrene in man.

Bacterium leucaemiae Migula. (Lucet, Jahresber. ü. Fortschr. in d. Lehre v. d. path. Mikroorg., *7*, 1891, 319; *Bacillus leucaemiae canis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 285; *Bacterium leucaemiae canis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 119; Migula, Syst. d. Bakt., *2*, 1900, 442; *Bacillus leucaemiae* Chester, Man. Determ. Bact., 1901, 264.) From a dog with leukemia.

Bacterium limbatum Migula. (*Bacterium limbatum acidi lactici* Marpmann,

Ergänzungshefte d. Centralb. f. allg. Gesundheitspflege, *2*, 122; *Bacillus limbatus acidi lactici* Sternberg, Man. of Bact., 1893, 645; Migula, Syst. d. Bakt., *2*, 1900, 407.) From fresh milk.

Bacterium lineola (Müller) Cohn. (*Vibrio lineola* Müller, Vermium Historia, 1773, 39; Cohn, Beitr. z. Biol. d. Pflanz., *1*, Heft 2, 1872, 170; *Bacillus lineola* Trevisan, I generi e le specie delle Batteriacee, 1889, 18.) From stagnant water, infusions, etc.

Bacterium lini Migula. (Winogradsky, Compt. rend. Acad. Sci., Paris, *121*, 1893, 742; Migula, Syst. d. Bakt., *2*, 1900, 513.) From retting hemp.

Bacterium linkoi Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 154.) From sea water.

Bacterium liquefaciens communis (Sternberg) Chester. (*Bacillus liquefaciens communis* Sternberg, Man. of Bact., 1893, 686; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 91; *Bacillus communis* Migula, Syst. d. Bakt., *2*, 1900, 725; not *Bacillus communis* Jackson, Jour. Inf. Dis., *8*, 1911, 241.) From the feces of yellow fever patients.

Bacterium litoreum Warming. (Warming, Danmarks Kyster levende Bakterier, 1875, 398; *Bacillus litoreus* Trevisan, I generi e le specie delle Batteriacee, 1889, 18.) From sea water.

Bacterium loculosum Migula. (Fächerbacillus, Clauss, Inaug. Diss., Würzburg, 1889, 27; Migula, Syst. d. Bakt., *2*, 1900, 408.) From milk.

Bacterium luceti Migula. (Lucet, Ann. Inst. Past., *3*, 1889, 401; *Bacillus cuniculicida thermophilus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 418; Migula, Syst. d. Bakt., *2*, 1900, 507; *Bacterium cuniculicida thermophilus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 83; *Bacterium cuniculicida* Chester, Man. Determ. Bact., 1901, 140.) Associated with an epizootic in rabbits and guinea pigs.

Bacterium ludwigi Karlinski. (Hyg. Rundschau, *5*, 1895, 685.) From the water of the hot springs at Ilidze in Bosnia.

Bacterium luteolum Henrici. (Henrici, Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 51; Migula, Syst. d. Bakt., *2*, 1900, 455.) From cheese.

Bacterium lutescens Migula. (Der gelbe Bacillus, Lustig, Diag. d. Bakt. d. Wassers, 1893, 78; Migula, Syst. d. Bakt., *2*, 1900, 476.) From water.

Bacterium luteum Adametz. (List, Inaug. Diss., Leipzig, 1885, 53; Adametz, Bakt. Nutz- u. Trinkwässer, Mitteil. d. österr. Versuchsstation für Brauerei und Mälzerei in Wien, 1888, 48.) From the stomach contents of sheep and from water.

Bacterium margarineum Migula. (Margarinbacillus α, Jolles and Winkler, Ztschr. f. Hyg., *20*, 1895, 102; Migula, Syst. d. Bakt., *2*, 1900, 410.) From margarine.

Bacterium marinum Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 238.) From sea water.

Bacterium maydis Maiocchi. (Maiocchi, Bollet. d. Accad. medic. d. Roma, October, 1881; *Bacillus maydis* Trevisan, I generi e le specie delle Batteriacee, 1889, 17.) From corn (maize) infusions.

Bacterium medanense Honing. (Cent. f. Bakt., II Abt., *37*, 1913, 382.) From the peanut plant (*Arachis hypogaea*).

Bacterium melolonthae liquefaciens Paillot. (Compt. rend. Soc. Biol., Paris, *68*, 1916, 1102.) From the cockchafer (*Melolontha melolontha*). According to the author's system of nomenclature, this is presumably a synonym of *Bacillus melolonthae liquefaciens α*.

Bacterium meningitidis (Neumann and Schaffer) Chester. (*Bacillus meningitidis purulentae* Neumann and Schaeffer, Arch. f. path. Anat., *109*, 1887, 477; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 71; *Bacillus neumanni* Migula, Syst. d. Bakt., *2*, 1900, 751; not *Bacillus neumanni* Herter, in Just, Botan. Jahresber., 2 Abt., *39*, Heft 4, 1915, 748; *Bacillus meningitidis* Chester,

Man. Determ. Bact., 1901, 213.) From pus from an individual who died of purulent meningitis.

Bacterium merismopedioides Zopf. (Zopf, Die Spaltpilze, 1 Aufl., 1883, 56; *Bacillus synchyseus* Trevisan, I generi e le specie delle Batteriacee, 1889, 18; *Bacterium synchyseus* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1022.) From canal water.

Bacterium microsporum Trevisan. (Trevisan, Rendic. d. Instit. Lombardo, Ser. 2, *13*, 1879; *Bacillus microtis* Trevisan, I generi e le specie delle Batteriacee, 1889, 18; *Bacterium microtis* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1025.) From water and putrefying infusions.

Bacterium minutum (Zimmermann) Migula. (*Bacillus minutus* Zimmermann, Die Bakterien unserer Trink- und Nutzwässer, Chemnitz, *2*, 1894, 56; Migula, Syst. d. Bakt., *2*, 1900, 423.) From water.

Bacterium monachae von Tubeuf. (v. Tubeuf, Forstlich - naturwissensch. Ztschr., *1*, 1892, 34; *Bacillus monachae* Migula, Syst. d. Bakt., *2*, 1900, 742.) From the larvae of a moth (*Lymantria monacha*).

Bacterium multipediculum (Flügge) Chester. (*Bacillus multipediculus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 323; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 104.) Isolated frequently as a contamination on potato media.

Bacterium muripestifer (Kruse) Chester. (Bacillus der Mäuseseuche, Laser, Cent. f. Bakt., *11*, 1892, 184; *Bacillus muripestifer* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 432; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 87.) From the spleen of a field mouse. Associated with a plague of field mice.

Bacterium nacreaceum (Zimmermann) Migula. (Perlmutterglänzender Bacillus, Keck, Inaug. Diss., Dorpat, 1890, 40; Eberbach, Inaug. Diss., Dorpat, 1890; *Bacillus nacreaceus* Zimmermann, Die Bakterien unserer Trink- und Nutzwässer, Chemnitz, *2*, 1894, 34; Migula, Syst. d. Bakt., *2*, 1900, 426.) From water.

Bacterium naphthalinicus Tausson. (Planta, *4*, 1927, 214.) From oil-soaked soils at Baku, Russia. Oxidizes naphthalene.

Bacterium nicolaieri Migula. (Kapselbacillus, Nicolaier, Cent. f. Bakt., *16*, 1894, 601; Migula, Syst. d. Bakt., *2*, 1900, 354.) Associated with purulent nephritis.

Bacterium nicotianum Bucherer. (Cent. f. Bakt., II Abt., *105*, 1942–43, 446.) From fermenting tobacco leaves.

Bacterium nicotinobacter Bucherer. (Cent. f. Bakt., II Abt., *105*, 1942, 170.) From a mixture of soil, manure and rotting materials. Gram-variable.

Bacterium nicotinophagum Bucherer. (Cent. f. Bakt., II Abt., *105*, 1942, 167.) From a mixture of soil, manure, and rotting materials. Also from fermenting tobacco leaves (*ibid.*, 446).

Bacterium nitens Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 459.) From the intestines of birds.

Bacterium nomae (Schimmelbusch) Migula. (*Bacillus nomae* Schimmelbusch, Deutsch. med. Wochnschr., 1889, No. 26; Migula, Syst. d. Bakt., *2*, 1900, 384.) Found in necrotic tissues.

Bacterium oblongum (Boutroux) DeToni and Trevisan. (*Micrococcus oblongus* Boutroux, Annales de l'École normale supérieure, Sér. 2, *5*, 1881, 67; *Bacillus oblongus* Trevisan, I generi e le specie delle Batteriacee, 1889, 16; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1021; *Bacterium gluconicum* Miquel and Cambier, Traité de Bact., 1902, 605; not *Bacterium gluconicum* Hermann, Biochem. Zeit., *192*, 1928, 198.) From vinegar. May be an acetobacter.

Bacterium ogatae Migula. (Ogata, Cent. f. Bakt., *9*, 1891, 442; Migula, Syst. d. Bakt., *2*, 1900, 389.) From dust.

Bacterium orchiticum (Kruse) Chester. (Bacillus zur Rotzdiagnose, Kutscher,

Ztschr. f. Hyg., *21*, 1895, 156; *Bacillus orchiticus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 455; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 99.) From nasal secretions of a glandered horse.

Bacterium osteophilum Billet. (Contribution à l'étude de la morphologie et du développement des Bactériacées, Bull. Sci. de la France et de la Belgique, Paris, *21*, 1890, 149.) From macerated human bones.

Bacterium ovale Migula. (Bacillus No. 17, Pansini, Arch. f. pathol. Anat. u. Physiol., *122*, 1890, 451; Migula, Syst. d. Bakt., *2*, 1900, 458; not *Bacterium ovale* Chester, Man. Determ. Bact., 1901, 171 (*Bacillus ovalis* Wright, Mem. Nat. Acad. Sci., *7*, 1895, 435).) From feces.

Bacterium ovatum Migula. (*Bacillus ovatus minutissimus* Unna-Tommasoli, Monatsh. f. prakt. Dermatol., *9*, 1889, 59; Migula, Syst. d. Bakt., *2*, 1900, 417; *Bacterium ovatus minutissimus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 139; not *Bacterium ovatum* Chester, Man. Determ. Bact., 1901, 177 (*Bacillus ruber ovatus* Bruyning, Arch. néerl. Sci. exact. et nat., Sér. II, 1898, 297).) From human skin with seborrheic eczema.

Bacterium pallens Henrici. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 36.) From cheese.

Bacterium pallescens Henrici. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 35.) From cheese.

Bacterium pallidum Henrici. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 34; *Ulvina pallida* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 76.) From cheese.

Bacterium pallidior Chester. (*Bacillus fuscus pallidior* Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 361; *Bacterium fuscus pallidior* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 111; Chester, Man. Determ. Bact., 1901, 171.) Culture received by Dyar from Kràl's laboratory labeled *Bacillus latericeus*. Dyar renames this because the culture does not agree with *Bacillus latericeus* Eisenberg. However, the 1900 Kràl catalogue indicates that this was *Bacillus latericeus* Adametz and Wichmann syn. ziegelrother Bacillus, Adametz; *Bacterium lactericeum* Lehmann and Neumann.

Bacterium papillare Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 149.) From sea water.

Bacterium paradoxus (Kruse) Chester. (Typhus ahnlicher Bacillus, Kruse and Pasquale, Ztschr. f. Hyg., *16*, 1894, 19; *Bacillus paradoxus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 373; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 71.) From the liver in a case of dysentery.

Bacterium paraviscosum Buchanan and Hammer. (Iowa Sta. Coll. Agr. Exp. Sta., Res. Bull. 22, 1915, 266.) Stated to be similar to *Bacterium viscosum* of various authors.

Bacterium patelliforme Honing. (Cent. f. Bakt., II Abt., *37*, 1913, 378.) From tobacco plants in Sumatra.

Bacterium pateriforme Migula. (*Bacillus albicans pateriformis* Unna-Tommasoli, Monatsh. prakt. Dermatol., *9*, 1889, 58; Migula, Syst. d. Bakt., *2*, 1900, 415.) Found on human skin with seborrheic eczema.

Bacterium petersii Migula. (Bacterium C, Peters, Botan. Zeitung, *47*, 1889; *Bacillus aceticus petersii* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 355; *Bacterium aceticus petersii* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 77; Migula, Syst. d. Bakt., *2*, 1900, 397; *Bacterium aceticum* Chester, Man. Determ. Bact., 1901, 127; not *Bacterium aceticum* Baginsky, Ztschr. f. phys. Chem., *12*, 1888, 437.) From fermenting dough.

Bacterium photometricum Engelmann. (Engelmann, Jour. Roy. Microscop. Soc., 1882, 656 and 1883, 256; *Bacillus photometricus* Trevisan, I generi e le specie delle Batteriacee, 1889, 18.) Saprophytic.

Bacterium piluliformans (Müller-Thur-

gau) Migula. (*Bacillus piluliformans* Müller-Thurgau, Jahresber. d. Versuchsstation zu Wädenswil 1892/3, *3*, 1894, 92; Migula, Syst. d. Bakt., *2*, 1900, 513.) From a disease of red wine.

Bacterium pituitosum Migula. (*Bacillus lactis pituitosi* Löeffler, Berliner klin. Wochnschr., 1887, 631; *Bacterium lactis pituitosi* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 86; Migula, Syst. d. Bakt., *2*, 1900, 403; *Bacterium lactis* Chester, Man. Determ. Bact., 1901, 148; not *Bacterium lactis* Baginsky, Ztschr. f. phys. Chem., *12*, 1888, 437.) From milk.

Bacterium pityocampae Dufrenoy. (Compt. rend. Soc. Biol., Paris, *71*, 1919, 288.) From diseased caterpillars of the processionary moth (*Cnethocampa pityocampa*).

Bacterium pleuropneumoniae Migula. (Diplococcus der Brustseuche der Pferde, Schütz, Arch. f. pathol. Anat. u. Physiol., *107*, 374; Migula, Syst. d. Bakt., *2*, 1900, 348.) Frequently isolated from horses with pneumonia.

Bacterium plicatum (Zimmermann) Chester. (*Bacillus plicatus* Zimmermann, Die Bakterien unserer Trink- und Nutzwässer, Chemnitz, *1*, 1890, 54; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 108; *Bacterium plicativum* Migula, Syst. d. Bakt., *2*, 1900, v and 453). From water.

Bacterium pneumopecurium Chester. (Bacillus of sporadic pneumonia of cattle, Smith, U. S. Dept. Agr. Bur. Animal Husbandry, 1895, 136; Chester, Man. Determ. Bact., 1901, 137.) Similar to *Pasteurella suilla*.

Bacterium pneumosepticum (Babes) Migula. (*Bacillus pneumosepticus* Babes, Progrès méd. roumain, *6*, 1889; not *Bacillus pneumosepticus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 408; Migula, Syst. d. Bakt., *2*, 1900, 377.) From a case of septic pneumonia.

Bacterium polymorphum (Frankland and Frankland) Migula. (*Bacillus polymorphus* Frankland and Frankland, Philos. Trans. Royal Soc. London, *178*, 1887, B, 275; Migula, Syst. d. Bakt., *2*, 1900, 420.) From air.

Bacterium porri Majocchi. (Majocchi, in Tommasi-Crudeli, Anatomia patologica, *1*, 1882; *Bacillus verrucae vulgaris* Kuhnemann, Monatsh. f. prakt. Dermatol., *9*, 1889; *Bacillus porri* Trevisan, I generi e le specie delle Batteriacee, 1889, 13.) From warts.

Bacterium prodeniae Metalnikov and Metalnikov. (Compt. rend. Acad. Agric., France, *18*, 1932, 206.) From a blackened dead larva of a moth (*Prodenia litura*).

Bacterium profusum (Frankland and Frankland) Migula. (*Bacillus profusus* Frankland and Frankland, Philos. Trans. Royal Soc. London, *178*, 1887, B, 276; Migula, Syst. d. Bakt., *2*, 1900, 421.) From air.

Bacterium pseudoaquatile Migula. (*Bacillus aquatilis* α, Tataroff, Inaug. Diss., Dorpat, 1891, 44; Migula, Syst. d. Bakt., *2*, 1900, 470.) From water.

Bacterium pseudoconjunctivilidis (Kruse) Chester. (Kartulis, Cent. f. Bakt., *1*, 1887, 289; *Bacillus pseudoconjunctivitidis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 441; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 108.) From conjunctival secretions.

Bacterium pseudofilicinum Migula. (Fadenbacillus, Maschek, Bakteriologische Untersuchungen der Leitmeritzer Trinkwässer, Leitmeritz, 1887; Migula, Syst. d. Bakt., *2*, 1900, 454.) From water.

Bacterium pseudoinfluenzae (Kruse) Chester. (Pseudoinfluenzabacillus, Pfeiffer, Ztschr. f. Hyg., *13*, 1893, 357; *Bacillus pseudoinfluenzae* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 439; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 66.) From water.

Bacterium pseudokeratomalaciae Migula. (Loeb, Cent. f. Bakt., *10*, 1891, 369; Migula, Syst. d. Bakt., *2*, 1900, 359.)

A capsulated bacterium from infected cornea of a child.

Bacterium pseudomultipediculum Migula. (*Bacillus multipediculus flavus* Zimmermann, Bakt. unser. Trink- u. Nutzwässer, Chemnitz, *2*, 1894, 42; Migula, Syst. d. Bakt., *2*, 1900, 332.) From sewage.

Bacterium pseudopneumonicum (Passet) Chester. (*Bacillus pseudopneumonicus* Passet, Untersuchungen über die Aetiologie der eiterigen Phlegmone des Menschen, 1885, 40; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 140; *Brucella pseudopneumonicum* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 68.) From pus.

Bacterium punctum (Mueller) Ehrenberg. (*Monas punctum* Mueller, Infusoria, 1786, 3; *Bacillus punctum* Trevisan, I generi e le specie delle Batteriacee, 1889, 18.) From swamps and stagnant water.

Bacterium putidum Chester. (*Bacillus gracilis cadaveris* Sternberg, Man. of Bact., 1893, 733; Chester, Man. Determ. Bact., 1901, 140.) From a liver.

Bacterium pyaemicum Migula. (Levy, Cent. f. klin. Med., 1890, No. 4; abst. in Cent. f. Bakt., *8*, 1890, 86; Migula, Syst. d. Bakt., *2*, 1900, 443.) From a case of pyemia.

Bacterium pyocinnabareum (Kruse) Chester. (Ferchmin, Ueber rote Eiterung, Wratsch, 1892, No. 24 and 25; abst. in Cent. f. Bakt., *13*, 1893, 103; *Bacillus pyocinnabareus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 304; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 113.) From a case of red pus.

Bacterium pyogenes Chester. (Fuchs, Inaug. Diss., Greifswald, 1890; *Bacillus pyogenes anaerobius* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 244; not *Bacillus pyogenes anaerobius* Béla-Johan, Cent. f. Bakt., I Abt., Orig., *87*, 1922, 290; *Bacterium pyogenes anaerobius* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 127; Chester, Man. Determ. Bact., 1901, 184; not *Bacterium pyogenes* Migula, Syst. d. Bakt., *2*, 1900, 381; not *Bacterium pyogenes* Ward, Jour. Bact., *2*, 1917, 619.) From stinking pus from a rabbit.

Bacterium pyraustae Nos. 1–7 Metalnikov and Chorine. (Internat. Corn Borer Invest., Sci. Repts., *1*, 1928, 52.) From diseased corn borer larvae (*Pyrausta nubilalis* Hb.).

Bacterium radiatum Chester. (Del. College Agr. Expt. Sta. Ann. Rept., *11*, 1900, 56.) From soil.

Bacterium ramificans Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 229.) From bean infusions.

Bacterium rangiferinum Honing. (Honing, Cent. f. Bakt., II Abt., *37*, 1913, 379; *Plocamobacterium rangiferinum* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 78.) From fermenting tobacco.

Bacterium repens Miehe. An organism associated with *Bacterium foliicola* de Jongh.

Bacterium retiformans Gicklhorn. (Cent. f. Bakt., II Abt., *50*, 1920, 421.) A sulfur bacterium from garden soil. See Manual, 5th ed., 1939, 86 for a description of this organism.

Bacterium rhizopodicum Migula. (*Bacillus rhizopodicus margarineus* Jolles and Winkler, Ztschr. f. Hyg., *20*, 1895, 105; Migula, Syst. d. Bakt., *2*, 1900, 452.) From margarine.

Bacterium roseum Losski. (Losski, Inaug. Diss., Dorpat, 1893; quoted from Migula, Syst. d. Bakt., *2*, 1900, 484; *Bacillus roseus* Nepveux, Thèse, Fac. Pharm., Paris, 1920, 115.) From sand.

Bacterium rubigenosum Kern. (Kern, Arb. bakt. Inst. Karlsruhe, *1*, Heft, 4, 1896, 456; *Bacillus rubigenosus* Nepveux, Thèse, Fac. Pharm., Paris, 1920, 113; not *Bacillus rubiginosus* Catiano, in Cohn, Beitr. z. Biol. d. Pflanzen, *7*, 1896, 538.) From the intestines of birds.

Bacterium rubrum Schneider. (*Bakterium rubrum* Schneider, Arb. bakt. Inst. Karlsruhe, *1*, Heft 2, 1894, 213; also see Migula, Syst. d. Bakt., *2*, 1900, 488; *Bacillus rubrum* Nepveux, Thèse,

Fac. Pharm., Paris, 1920, 115.) From swamp water. Difficult to distinguish from *Bacterium erythromyxa*.

Bacterium rubrum Metalnikov and Metalnikov. (Compt. rend. Acad. Agric., France, *18*, 1932, 204; not *Bacterium rubrum* Schneider, Arb. bact. Inst. Karlsruhe, *1*, Heft 2, 1894, 213.) From the cotton worm (*Gelechia gossypiella*).

Bacterium salivae Migula. (*Bacillus salivae minutissimus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 440; *Bacterium salivae minutissimus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 86; Migula, Syst. d. Bakt., *2*, 1900, 418.) From secretions of the mouth.

Bacterium salmonicida Lehmann and Neumann. (Bacillus der Forellenseuche, Emmerich and Weibel, Arch. f. Hyg., *21*, 1894, 1; Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 240; *Bacillus salmonicida* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 322; *Bacterium salmonica* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 99; see Mackie et al., Final Rept. of the Furunculosis Committee, H. M. Stationery Office, Edinburgh, 1935; and Duff, Jour. Bact., *34*, 1937, 49.) Pathogenic for trout.

Bacterium sanguinis Migula. (*Bacillus sanguinis typhi* Sternberg, Man. of Bact., 1893, 732; *Bacterium sanguinis typhi* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 89; Migula, Syst. d. Bakt., *2*, 1900, 506.) From the blood of typhus fever patients.

Bacterium schüffneri Honing. (Cent. f. Bakt., II Abt., *37*, 1913, 370.) From tobacco plants in Sumatra.

Bacterium septentrionale Issatchenko. (Recherches sur les microbes de l Océan Glacial Arctique (in Russian). Petrograd, 1914, 239.) From sea water.

Bacterium (*Proteus*) *septicus* (Babes) Chester. (*Proteus septicus* Babes, Septische Processe des Kindesalters, 1889; *Bacillus proteus septicus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 279; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 102; *Bacillus septicus* Chester, Man. Determ. Bact., 1901, 245; not *Bacillus septicus* Macé, Traité pratique de Bact., 1st ed., 1889, 455; not *Bacillus septicus* Migula, Syst. d. Bakt., *2*, 1900, 646; not *Bacillus septicus* Crookshank, Textb. of Bact., 4th ed., 1900, 632.) From the intestine of a child having septicemia.

Bacterium setosum Henrici. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 46.) From cheese.

Bacterium siccum Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 235.) From sea water.

Bacterium sieberti Migula. (Siebert, Inaug. Diss., Würzburg, 1894, 13; Migula, Syst. d. Bakt., *2*, 1900, 456.) From hair follicles.

Bacterium soriferum Migula. (Severin, Cent. f. Bakt., II Abt., *1*, 1895, 799; Migula, Syst. d. Bakt., *2*, 1900, 438.) From manure.

Bacterium spiniferum (Unna-Tommasoli) Chester. (*Bacillus spiniferus* Unna-Tommasoli, Monatsh. f. prakt. Dermatol., *9*, 1889, 58; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 110 and 143.) From human skin with seborrheic eczema.

Bacterium spinosum Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 219.) From fermenting beets.

Bacterium spirale Issatchenko. (Recherches sur les microbes de l'Océan Glacial Arctique (in Russian). Petrograd, 1914, 238.) From sea water.

Bacterium sputigenum Chester. (*Bacillus aerogenes sputigenus capsulatus* Herla, Archiv de Biol., *14*, 1895, 403; Chester, Man. Determ. Bact., 1901, 133; not *Bacterium sputigenum* Migula, Syst. d. Bakt., *2*, 1900, 378.) From the blood of a mouse which had been inoculated with the sputum of a pneumonia patient.

Bacterium sputigenum Migula. (Kreibohm, Inaug. Diss., Helmstedt, 1898, 29; Migula, Syst. d. Bakt., *2*, 1900, 378.) From the mouth.

Bacterium squamatum Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 242.) From vegetable infusions.

Bacterium squamosum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1897, 436.) From the stomachs and intestines of birds.

Bacterium stalactitigenes Honing. (Cent. f. Bakt., II Abt., *37*, 1913, 375.) From tobacco plants in Sumatra.

Bacterium sternbergii Migula. (*Bacillus anaerobius liquefaciens* Sternberg, Man. of Bact., 1893, 693; Migula, Syst. d. Bakt., *2*, 1900, 444; *Bacterium anaerobicum* Chester, Man. Determ. Bact., 1901, 198; *Bacillus sternbergii* Winslow, Kligler and Rothberg, Jour. Bact., *4*, 1919, 487.) From intestines of yellow fever cadavers.

Bacterium steroidiclasium Arnaudi and Ercoli. (Boll. Sez. ital. Soc. intern. Microbiol., *20* (3), 1941, 000; also see Arnaudi, Cent. f. Bakt., II Abt., *105*, 1942–43, 352.) Source not given in second paper. From bakers' yeast.

Bacterium streckeri (Trevisan) Migula. (*Bacillus citreus cadaveris* Strassmann and Strecker, Ztschr. f. Medizinalbeamte, 1888, No. 3; *Bacillus streckeri* Trevisan, I generi e le specie delle Batteriacee, 1889, 17; *Bacterium citreus cadaveris* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 108; Migula, Syst. d. Bakt., *2*, 1900, 460; *Bacterium citreum* Chester, Man. Determ. Bact., 1901, 167.) From a cadaver.

Bacterium subcitricum Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 257.) From vegetable infusions.

Bacterium subfuscum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 461.) From the intestines of birds.

Bacterium subluteum Migula. (*Bacillus luteus* von Dobrzyniecki, Cent. f. Bakt., I Abt., *21*, 1897, 835; Migula, Syst. d. Bakt., *2*, 1900, 456.) From the mouth.

Bacterium sulfureum Holschewnikoff. (Holschewnikoff, Fortschr. d. Med., *7*, 1889, 204 and Ann. de Microgr., *1*, 1888–1889, 261; *Bacillus sulfureus* Trevisan, I generi e le specie delle Batteriacee, 1889, 17.) From sewage.

Bacterium sumatranum Honing. (Cent. f. Bakt., II Abt., *37*, 1913, 374.) From tobacco plants in Sumatra.

Bacterium surgeri (Dornic and Daire) Buchanan and Hammer. (*Bacillus surgeri* Dornic and Daire, Bull. mens. de l'Office de renseignements agricoles, *6*, 1907, 146; Buchanan and Hammer, Iowa Sta. Coll. Agr. Exp. Sta., Res. Bull. 22, 1915, 254.) From serum produced in the manufacture of casein. Causes slimy milk. Closely related to the *Bacterium bulgaricum* group, according to Buchanan and Hammer.

Bacterium sycosiferum Migula. (*Bacillus sycosiferus foetides* Unna-Tommasoli, Monatsh. f. prakt. Dermatol., *8*, 1889, 183; Migula, Syst. d. Bakt., *2*, 1900, 385.) From the beard of a patient with bacillogenic sycosis.

Bacterium syphilidis (Kruse) Migula. (Syphilisbacillus, Lustgarten, Wiener med. Wochnschr., 1884 and Wiener med. Jahrbücher, 1885; *Pacinia syphilitica* Trevisan, I generi e le specie delle Batteriacee, 1889, 23; *Bacillus syphilidis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 514; Migula, Syst. d. Bakt., *2*, 1900, 496.) From syphilis.

Bacterium tachytonum Fischer. (Fischer, Deutsche med. Wochnschr., 1894, No. 25–28; *Bacillus tachytonus* Migula, Syst. d. Bakt., *2*, 1900, 655.) From feces in a case of cholera.

Bacterium tenue Migula. (*Bacillus tenuis sputigenes* Pansini, Arch. f. path. Anat., *122*, 1890, 453; *Bacillus sputigenus tenuis* (sic) Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 431; *Bacterium sputigenes tenuis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 89; Migula, Syst. d. Bakt., *2*, 1900, 457.) Associated with advanced phthisis and catarrhal pneumonia.

Bacterium termo (Mueller) Ehrenberg. (*Monas termo* Mueller, Infusoria, 1786; Ehrenberg, Abhandl. Akad. Berl., 1830; *Palmella infusionum* Ehrenberg, Infusionsthierchen, 1838, 526; *Zoogloea*

termo Cohn, Nova Acta Leop. Carol., *24*, 1853, 123; *Bacillus termo* Trevisan, I generi e le specie delle Batteriacee, 1889, 18.) From infusions.

Bacterium termo var. *subterraneum* Hansgirg. (Hansgirg, Oest. Bot. Ztschr., 1888, 6; quoted from DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1025.) From damp walls in a cellar.

Bacterium thiogenes Lehmann. (Thionsäurebakterien, Trautwein, Cent. f. Bakt., II Abt., *53*, 1921, 513; *ibid.*, *61*, 1924, 1; Lehmann, in Lehmann and Neumann, Bakt. Diag., 7th Aufl., *2*, 1927, 516; *Thiobacillus trautweinii* Bergey et al., Manual, 2nd ed., 1925, 39.) From canal water, sewage and soil. Regarded by Trautwein (*loc. cit.*, 1924, 5) as closely related to *Bacterium denitrificans* Lehmann and Neumann. See *Flavobacterium denitrificans* Bergey et al. Heterotrophic and therefore wrongly placed in *Thiobacillus* (Starkey, Jour. Bact., *28*, 1934, 387; Jour. Gen. Physiol., *18*, 1935, 325).

Bacterium tholoeideum Gessner. (Gessner, Arch. f. Hyg., *9*, 1889, 129; *Bacillus tholoeideus* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 952.) From the human duodenum.

Bacterium tortuosum Zukal. (Zukal, Verh. d. zoolog. botan. Gesellsch., Wien, *35*, 1885; *Bacillus tortuosus* Trevisan, I generi e le specie delle Batteriacee, 1889, 18; not *Bacillus tortuosus* Debono, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 233.) From muddy water.

Bacterium tremulans Ehrenberg. (Ehrenberg, Abhandlungen d. Berliner Akad., 1830, 38; *Vibrio tremulans* Ehrenberg, Die Infusionsthierchen, 1838, 79; Trevisan, Rend. Ist. Lomb., 1879, 145; *Bacillus tremulans* Trevisan, I generi e le specie delle Batteriacee, 1889, 18.) From stagnant water, infusions, etc.

Bacterium trichorrhexidis Migula. (*Bacillus multiformis trichorrhexidis* Hodara, Monatsh. f. prakt. Dermatol., *19*, 1894, 173; Migula, Syst. d. Bakt., *2*, 1900, 437.) From healthy hair showing trichorrhexis.

Bacterium truncatum Chester. (Bacillus No. XII, Adametz, Landwirtsch. Jahrb., *18*, 1889; Chester, Man. Determ. Bact., 1901, 157; not *Bacterium truncatum* Migula, Syst. d. Bakt., *2*, 1900, 407; not *Bacterium truncatum* Chester, *loc. cit.*, 195.) From Emmenthal cheese.

Bacterium tuberosum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 455; *Bacillus tuberosus* Nepveux, Thèse, Fac. Pharm., Paris, 1920, 113.) From the intestines of birds.

Bacterium turcosum. (Quoted from Franke and Rudloff, Biochem. Ztschr., *310*, 1942, 207.) Source not given.

Bacterium uniforme Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 250.) From fermenting malt.

Bacterium ureae Leube and Graser. (Leube and Graser, Arch. f. pathol. Anat. u. Physiol., *100*, 1885, 558; *Bacillus ureae* Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 357; not *Bacillus ureae* Miquel, Bull. Soc. Chim. d. Paris, *31*, 1879, 391; *Urobacillus leubei* Miquel and Cambier, Traité de Bactériologie, Paris, 1902, 635; not *Urobacillus leubei* Beijerinck, Cent. f. Bakt., II Abt., 7, 1901, 51; *Plocamobacterium ureae* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 78.) From urine. Leube makes no statement regarding spore formation. While Miquel's and Leube's organisms are sometimes regarded as having been identical, Miquel did not regard his *Bacillus ureae* as being identical with Leube's *Bacterium ureae* and gave them separate names *Urobacillus duclauxii* and *Urobacillus leubei* (Miquel and Cambier, *loc. cit.*, 631 and 635). The latter name had however been previously used by Beijerinck (*loc. cit.*) for a different organism. Dyar credits the name *Bacillus ureae* to Jaksch (Ztschr. f. physiol. Chem., *5*, 1881, 395) who, however, spoke only of a Harnstoffpilz and evidently had no pure cultures. Dyar's culture which came from Král is listed in the 1900 Král catalogue as

Bacillus ureae Leube. Also see Gibson (Jour. Bact., *24*, 1935, 493). Löhnis (Handb. f. landwirtsch. Bakt., 1910, 459) thinks that this species belongs in the *Proteus* group.

Bacterium vaillardi Migula. (Kelsch and Vaillard, Ann. Inst. Past., *4*, 1890, 276; Migula, Syst. d. Bakt., *2*, 1900, 437.) Found in swellings of the lymph system in leukemia.

Bacterium varicosum Migula. (Gombert, Recherches expér. microbes conjonctives, Paris, 1889; *Bacillus varicosus conjunctivae* Sternberg, Man. of Bact., 1893, 474; *Bacterium varicosus conjunctivae* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 100; Migula, Syst. d. Bakt., *2*, 1900, 444.) From the normal conjunctiva of man.

Bacterium variosum Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 218.) From vegetable infusions.

Bacterium velatum Migula. (*Bacillus tuberigenus 5*, Gonnermann, Landwirtsch. Jahrb., *23*, 1894, 657; Migula, Syst. d. Bakt., *2*, 1900, 454; *Bacillus velatus* Nepveux, Thèse, Fac. Pharm., Paris, 1920, 113.) From lupine root nodules.

Bacterium vernicosum Zopf. (Zopf, Beitr. z. Physiol. u. Morphol. niederer Organismen, Heft 1, 1892, 63; *Bacillus vernicosus* Migula, Syst. d. Bakt., *2*, 1900, 781.) From cotton-seed meal.

Bacterium vesiculosum Henrici. (Arb. a. d. bakt. Inst. d. techn. Hochschule zu Karlsruhe, *1*, Heft, 1, 1894, 37.) From cheese.

Bacterium villosum (Keck) Migula. (*Bacillus villosus* Keck, Inaug. Diss., Dorpat, 1890, 47; Migula, Syst. d. Bakt., *2*, 1900, 429; *Plocamobacterium villosum* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 79.) From water.

Bacterium vinicola Migula. (*Bacillus viscosus vini* Kramer, Bakteriol. in ihren Beziehungen z. Landwirtsch., *2*, 1892, 144; Migula, Syst. d. Bakt., *2*, 1900, 510.) From wine.

Bacterium viniperda Migula. (*Bacillus saprogenes vini IV*, Kramer, Bakteriol. in ihren Beziehungen z. Landwirtsch., *2*, 1892, 135; Migula, Syst. d. Bakt., *2*, 1900, 446.) From diseased wine.

Bacterium viride van Tieghem. (Bull. Soc. bot. France, *27*, 1880, 174.) Found on a fungus.

Bacterium viscidum Migula. (*Bacillus viscosus margarineus* Jolles and Winkler, Ztschr. f. Hyg., *20*, 1895, 104; Migula, Syst. d. Bakt., *2*, 1900, 450.) From margarine.

Bacterium viscosum Migula. (*Bacillus viscosus sacchari* Kramer, Sitzungsb. d. kais. Akad. d. Wiss., Wien, 1889; Bakteriol. in ihren Beziehungen z. Landwirtsch., *2*, 1892, 156; Migula, Syst. d. Bakt., *2*, 1900, 447.) Similar to *Leuconostoc mesenteroides* except that it liquefies gelatin.

Bacterium viscosum non-liquefaciens Stutzer and Wsorow. (Cent. f. Bakt., II Abt., *71*, 1927, 117.) From pupae of moth (*Euxoa segetum*). Resembles *Bacillus viscosus* Frankland.

Bacterium vitulinum Chester. (Bacillus der Septikämie bei einem Seekalbe, Bosso, Cent. f. Bakt., *25*, 1899, 52; Chester, Man. Determ. Bact., 1901, 143.) From a septicemia of the sea-calf (*Phoca vitulina*).

Bacterium vitulorum Migula. (Bacillus der weissen Ruhr der Kälber, Jensen, Monatsh. f. prakt. Tierheilk., *3*, 1892, 92; Maanedskrift for Dyrlaeger, *4*, 1892–93, 140; *Bacillus dysenteriae vitulorum* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 412; *Bacterium dysenteriae vitulorum* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 86; Migula, Syst. d. Bakt., *2*, 1900, 394; *Bacterium dysenteriae* Chester, Man. Determ. Bact., 1901, 145.) Associated with dysentery of calves.

Bacterium winkleri Migula. (Margarinbacillus *β*, Jolles and Winkler, Ztschr. f. Hyg., *20*, 1895, 102; Migula, Syst. d. Bakt., *2*, 1900, 485.) From margarine.

Bacterium wrightii Chester. (Capsule Bacillus of Mallory and Wright,

Ztschr. f. Hyg., *20*, 1895, 220; Chester, Man. Determ. Bact., 1901, 133.) From a case of bronchopneumonia.

Bacterium zinnioides Honing. (Cent. f. Bakt., II Abt., *37*, 1913, 371.) From tobacco, peanut and other plants in Sumatra.

Bacterium zuernianum (List) Chester. (*Bacillus zuernianus* List, Inaug. Diss., Leipzig, 1885, 36; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 83.) From fresh manure and intestines of sheep; also found in water.

Coccobacillus acridiorum Picard and Blanc. (Coccobacille des sauterelles, d'Herelle, Compt. rend. Acad. Sci. Paris, *152*, 1911, 1413; Picard and Blanc, *ibid.*, *156*, 1913, 1335; *Bacillus acridiorum* Chatton, *ibid.*, *156*, 1913, 1708.) From a locust (*Schistocerca americana* Drury).

Coccobacillus cajae Picard and Blanc. (Compt. rend. Acad. Sci., Paris, *156*, 1913, 1334; *Bacillus cajus* Marchol, Revue de Phytopath. Appl., *1*, 1914, 11.) From diseased caterpillars of *Arctia caja*.

Coccobacillus gibsoni Chorine. (Internat. Corn Borer Invest., Sci. Repts., *2*, 1929, 42; *B. gibsoni* Paillot, *B.* presumably indicates *Bacterium*, see index, p. 522, L'infection chez les insectes, 1933, 134; *Bacillus gibsoni* Steinhaus, Bacteria Associated Extracellularly with Insects, Minneapolis, 1942, 58.) From diseased corn borer larvae (*Pyraustra nubilalis*).

Coccobacillus insectorum Hollande and Vernier. (Compt. rend. Acad. Sci., Paris, *171*, 1920, 207.) From diseased caterpillars of a moth (*Malacosoma castrensis*).

Coccobacillus insectorum var. *malacosomae* Hollande and Vernier. (Compt. rend. Acad. Sci., Paris, *171*, 1920, 208.) From diseased caterpillars of a moth (*Malacosoma castrensis*).

Denitrobacterium thermophilum Ambroz. (Cent. f. Bakt., II Abt., *37*, 1913, 3.) A thermophilic bacterium from soil.

Diplobacillus melolonthae Paillot. (Compt. rend. Soc. Biol., Paris, *69*, 1917, 5; Annales des Épiphyties, *8*, 1922, 117.) From larvae of cockchafers (*Melolontha melolontha*).

Diplobacillus pieris Paillot. (Annales des Épiphyties, *8*, 1922, 129.) From diseased caterpillars of the cabbage butterfly (*Pieris brassicae*).

Helicobacterium aerogenes Miller. (Deutsche Med. Wchnschr., *12*, 1886, 119; *Bacillus helicoides* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 952.) From the stomach. This is the type species of the genus *Helicobacterium*.

Helicobacterium klebsii Miller. (Die Mikroorganismen der Mundhöhle, 2 Aufl., Leipzig, 1892, 370; quoted from Buchanan, Gen. Syst. Bact., Baltimore, 1925, 327.) From the mouth.

Microbacillus citreus baregensis Robine and Hauduroy. (Compt. rend. Soc. Biol., Paris, *98*, 1928, 26.) From hot sulfur springs at Barèges. Fourment (Compt. rend. Soc. Biol., Paris, *98*, 1928, 588) states that this species is *Bacillus luteus* Flügge, but Robine and Hauduroy (Compt. rend. Soc. Biol., Paris, *99*, 1928, 317) deny this.

Micrococcobacillus necroticans Pascheff. (See Pascheff, Bericht. d. ophthalmol. Gesellsch., Heidelberg, 1916, 418 or Klin. Monatsbl. f. Augenheilk., *57*, 1916, 517 and *58*, 1917, 97; *Coccobacillus polymorphus necroticans*, quoted from Bayer and v. Herrenschwand, Arch. f. Ophthalmol., *98*, 1919, 358; *Micrococcobacillus polymorphus necroticans* Pascheff, Arch. d'Ophthalmol., *38*, 1921, 28; Pascheff, *ibid.*, 97.) From the human eye. Reported as the causal organism of conjunctivitis.

Nitrosobacillus thermophilus Campbell. (Sci., *75*, 1932, 23.) From soil. Oxidizes ammonia to nitrite.

Pacinia ferrarii Trevisan. (Bacillo dell' ulcera molle, Ferrari, 1885; Trevisan, I generi e le specie delle Batteriacee, 1889, 23.)

Pacinia fickii Trevisan. (Bacillus e des Conjunctivalsackes, Fick, 1887; Trevisan, I generi e le specie delle Batteriacee, 1889, 23.)

Pacinia micheli Trevisan. (Michel, Luftstäbchen des Conjunctivalsecretes, 1882; Trevisan, I generi e le specie delle Batteriacee, 1889, 23.) From the conjunctiva.

Plocamobacterium acidi lactici Pribram. (Lange Milchsaurestäbchen, Wolff, Cent. f. Bakt., II Abt., *20*, 1908, 545; Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 76.) From milk.

Plocamobacterium epidermidis (Bizzozero) Pribram. (*Leptothrix epidermidis* Bizzozero, Arch. f. path. Anat., *98*, 1896, 455; Pribram, *loc. cit.*, 77.) From the skin.

Plocamobacterium proteolyticum (Wollman) Pribram. (*Glycobacter proteolyticus* Wollman, Ann. Inst. Past., *26*, 1912, 617; Pribram, *loc. cit.*, 118.)

Plocamobacterium rubrum Pribram, *loc. cit.*, 78. Red cheese bacterium (Kiel).

Plocamobacterium tilsitense Pribram, *loc. cit.*, 78. From Tilsit cheese (Kiel).

Proteus hominis Bordoni-Uffreduzzi. (Bacterium, Bordoni-Uffreduzzi and Di Mattei, Arch. per le scienze mediche, *10*, 1886, No. 7; abst. in Cent. f. Bakt., *1*, 1887, 345; Bordoni-Uffreduzzi, Ztschr. f. Hyg., *3*, 1888, 333; *Proteus hominis capsulatus* Bordoni-Uffreduzzi, *ibid.*; *Proteus capsulatus septicus* Banti, Lo Sperimentale, *88*; *Klebsiella bordonii* Trevisan, I generi e le specie delle Batteriacee, 1889, 25; *Bacillus capsulatus septicus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 345; *Bacterium hominis capsulatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 136; *Bacterium capsulatus* and *Bacterium capsulatus septicus* Chester, *ibid.*, 130; *Bacterium proteus* Migula, Syst. d. Bakt., *2*, 1900, 362; *Bacterium bordonii* Chester, Manual of Determ. Bact., 1901, 152.) From a case of ragpicker's disease which may have been anthrax or malignant edema.

Urobacillus beijerinckii Christensen. (Christensen, Cent. f. Bakt., II Abt., *27*, 1910, 357; *Bacillus beijerinckii* De Rossi, Microbiologia Agraria e Technica, 1927, 646.) From humus. Utilizes urea.

Urobacillus jakschii Söhngen. (Söhngen, Cent. f. Bakt., II Abt., *23*, 1909, 93; *Bacillus jakschii* De Rossi, Microbiologia Agraria e Technica, 1927, 646.) From garden earth. Utilizes urea.

Urobacillus miquelii Beijerinck. (Cent. f. Bakt., *7*, 1901, 47.) From garden earth. Löhnis (Handb. f. landwirtsch. Bakt., 1910, 459) regards this as belonging to the genus *Proteus*.

Urobacillus schützenbergii I and *II* Miquel. (Miquel, Ann. de Micrograph., *5*, 1893, 321 and 323; *Bacillus schützenbergii* Migula, Syst. d. Bakt., *2*, 1900, 727.) From sewage and river water. These may belong to *Proteus* (Löhnis, Handb. f. landwirtsch. Bakt., 1910, 459).

Urobacterium aerophilum Rubentschik. (Cent. f. Bakt., II Abt., *66*, 1925, 175.) From salt water, Lake Liman near Odessa.

Urobacterium citrophilum Rubentschik. (Cent. f. Bakt., II Abt., *66*, 1925, 172.) From black mud and salt water, Lake Liman near Odessa.

Viscobacterium lactis foetidum Laxa. (Cent. f. Bakt., II Abt., *95*, 1936, 130.) From milk having a fetid odor.

APPENDIX TO SUBORDER EUBACTERIINEAE

Record of species and synonyms discovered too late to be entered in the main body of the text. Arranged alphabetically by genera.

Acetobacter aceti (Kützing) Beijerinck syn. *Bacterium aceticus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 77.

Acetobacter acetosum Bergey et al. syn. *Ulvina acetosa* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 75.

Acetobacter ascendens Bergey et al. syn. *Ulvina ascendens* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 75.

Acetobacter diversum Humm. (Duke Univ. Marine Lab., North Carolina, Bull. 3, 1946, 63.) From sea water, Beaufort, North Carolina and marine algae, Miami, Florida. Digests agar.

Acetobacter mobile Tŏsić and Walker. (Jour. of Brewing, *50*, 1944, 296.) From bottled ale.

Acetobacter pasteurianum (Hansen) Beijerinck syn. *Bacillus pasteurianum* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 314; not *Bacillus pasteurianus* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 82; *Ulvina pasteuriana* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 76.

Acetobacter potens Humm. (Duke Univ. Marine Lab., North Carolina, Bull. 3, 1946, 63.) From intertidal sand, Beaufort, North Carolina. Digests agar.

Acetobacter rancens Beijerinck syn. *Ulvina rancens* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 76.

Acetobacter singulare Humm. (Duke Univ. Marine Lab., North Carolina, Bull. 3, 1946, 62.) From sea water, Beaufort, North Carolina. Digests agar.

Acetobacter xylinum (Brown) Holland syn. *Bacillus xylinus* Trevisan, I generi e le specie delle Batteriacee, 1889, 16; *Ulvina xylina* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 76.

Achromobacter caseinicum Gahl. (Jour. Bact., *16*, 1928, 38.) From a solution of sodium caseinate. Polar flagellate. Possibly a strain of *Pseudomonas fluorescens* Migula that had lost the power of forming pigment.

Achromobacter nijibetsui Takeda. (Cent. f. Bakt., II Abt., *94*, 1936, 48.) From diseased salmon eggs. Not found to be virulent. A polar-flagellated, Gram-negative, yellow chromogen, presumably belonging in the genus *Xanthomonas*.

Actinobacillus actinomycetemcomitans Topley and Wilson syn. *Bacillus actinomycetemcomitans* Rosebury, Bact. Rev., *8*, 1944, 205.

Aerobacter liquefaciens Beijerinck. (Cent. f. Bakt., II Abt., *6*, 1900, 199; not *Aerobacter liquefaciens* Grimes and Hennerty, Sci. Proc. Roy. Dublin Soc., (N.S.) *20*, 1931, 93.) From mud and water in swamps. Monotrichous, otherwise like *Aerobacter cloacae*. This may have been a species of gas-forming *Pseudomonas*.

Aerobacter tartarivorum Nijdam. (Thesis, Leiden, 1907.) Decomposes d-tartrates. Probably identical with *Aerobacter aerogenes* (Vaughn, Marsh, Stadtman and Cantino, Jour. Bact., *52*, 1946, 324).

Alcaligenes marshallii Bergey et al. syn. *Bacterium marshalli* Buchanan and Hammer, Iowa Sta. Coll. Agr. Exp. Sta., Res. Bull. 22, 1915, 272.

Alcaligenes viscosum Weldin syn. *Plocamobacterium viscosum* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 79.

Ascococcus buccalis Miller. (Die Mikroorganismen der Mundhöhle, Leipzig, 1889, 65.) From the mouth.

Bacillus annulatus Wright Syn. *Bacterium annulatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 105.

Bacillus cubonianus Macchiati syn. *Bacterium cubonianus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 132.

Bacillus duplicatus Wright. (Wright, Mem. Nat. Acad. Sci., *7*, 1895, 457; *Bacterium duplicatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 90.) From Schuylkill River water. Monotrichous.

Bacillus fluorescens mutabilis Wright. (Wright, Mem. Nat. Acad. Sci., *7*, 1895, 449; *Bacterium fluorescens mutabilis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 120.) From Schuylkill River water.

Bacillus fluorescens nivalis Eisenberg syn. *Bacterium fluorescens nivalis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 120.

Bacillus haydocki Henneberg syn. *Plocamobacterium haydocki* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 77.

Bacillus influenzoides apis White. (Jour. Path. and Bact., *24*, 1921, 71.) From intestine of bee. Monotrichous.

Bacillus mesentericus aureus Winkler syn. *Bacillus winkleri* Chester, Man. Determ. Bact., 1901, 256.

Bacillus pabuli acidi II Weiss syn. *Plocamobacterium pabuli* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 78.

Bacillus vaginae Kruse syn. *Bacterium vaginae* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 67.

Bacillus viridi-luteus Trevisan. (Grüngelber Bacillus, Eisenberg, Bakt. Diag., 1 Aufl., 1886, 10; Trevisan, I generi e le specie delle Batteriacee, 1889, 19.) From water. This probably was the same as *Bacillus fluorescens* Trevisan, *ibid.*, 19 and *Pseudomonas fluorescens* Migula.

Bacillus wortmannii Henneberg syn. *Plocamobacterium wortmanni* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 79.

Bacterium granulosum Lehmann and Neumann syn. *Plocamobacterium granulosum* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 77.

Bacterium lipolyticum Huss syn. *Kurthia lipolyticum* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 75.

Bacterium orleanense Henneberg syn. *Ulvina orleanensis* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 75.

Bacterium xylinoides Henneberg syn. *Ulvina xylinoides* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 76.

Brucella byzantinea (Montsouris) Pribram. (*Coccobacterium byzantineum* Montsouris, quoted from Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 67; Pribram, *idem.*)

Brucella cocciformis (Jaiser) Pribram. (*Bacterium cocciforme* Jaiser, quoted from Pribram, Klassifikation der Schizomyceten, 1933, 67; *Coccobacterium thermophilum* Negre, Compt. rend. Soc. Biol., Paris, *75*, 1913, 814 and 867; Pribram, *idem.*) From sputum.

Chlorobacterium lactis Guillebeau. (Landw. Jahrb. d. Schweiz., *4*, 1890, 32.) From the udder of cows with mastitis. Produces a green pigment. Presumably identical with *Pseudomonas aeruginosa* Migula. The type species of the genus *Chlorobacterium* Guillebeau.

Chromobacterium chocolatum Knutsen. (Quoted from Lasseur, Dupaix-Lasseur and Melcion, Travaux du Lab. de Microbiol., Fac. Pharm. de Nancy, Fasc. XIII, 1942–43–44, 1944, 164, 187, 293, and 313.) Isolated by M. H. Knutsen, State Coll., Pennsylvania. Source not known. Dull violet with brown tinge. Disso-

ciates into a violet and an orange strain (*Chromobacterium orangium* Knutsen, *loc. cit.*, 294).

Chromobacterium iodinum Davis. (Davis, Cent. f. Bakt., II Abt., *100*, 1939, 273; also see Clemo and McIlwain, Jour. Chem. Soc., Pt. 1, 1938, 479; *Pseudomonas iodinum* Tobie and *Pseudomonas clemo* Tobie, Bull. Assoc. des Diplômés de Microbiol., Fac. Pharm. Nancy, No. 18, 1939, 16.) From plate inoculated with milk. This non-motile organism does not have the characters of *Chromobacterium* sensu stricto so that this species is retained with *Bacterium* for the present.

Coccus cumulus minor Black. (Trans. Ill. State Dental Soc., *22*, 1886, 192.) From the mouth.

Corynebacterium hemolyticum MacLean, Liebow and Rosenberg. (Jour. Inf. Dis., *79*, 1946, 69.) From infections among American soldiers and natives in the South and West Pacific. Similar in many ways to *Corynebacterium pyogenes* and *C. ovis*.

Corynebacterium piriforme Honing. (Cent. f. Bakt., II Abt., *37*, 1913, 383.) From tobacco plants in Sumatra.

Diplococcus aquatilis Vaughan. (Amer. Jour. Med. Sci., *104*, 1892, 184.) From water.

Diplococcus glycinophilus Cardon and Barker. (Jour. Bact., *52*, 1946, 629.) From marine mud.

Diplococcus luteus Adametz and Wichmann. (Adametz and Wichmann, Die Bakterien der Trink- und Nutzwässer, Mitt. Oest. Versuchsstat. f. Brauerei u. Mälzerei, Heft 1, 1888, 49; *Planococcus luteus* Migula, Syst. Bakt., *2*, 1900, 274.) From water.

Escherichia Castellani and Chalmers syn. *Colibacter* Pestana and Andrade, Ann. Paulistas de Med. e Cir., *39*, 1940, 462.

Escherichia coli Castellani and Chalmers syn. *Colibacter commune* Pestana and Andrade, *loc. cit.*

Flavobacterium harrisonii Bergey et al. syn. *Bacillus harrisonii* Buchanan and Hammer, Iowa Sta. Coll. Agr. Exp. Sta., Res. Bull. 22, 1915, 257.

Flavobacterium tabidum Kimata. (Cent. f. Bakt., II Abt., *105*, 1942, 120.) From spoiled semi-dried fish (*Trachurus japonicus*). Polar flagellate.

Fusiformis grandis Grassé. (Compt. rend. Soc. Biol., Paris, *94*, 1926, 1014; Arch. Zool. Expér. et Gén., *65*, 1926, 463.) From the surface of the body of a flagellate (*Polymastix melolonthae*), in the intestine of larvae of beetles and tipulids, possibly also free in the intestine of the insects.

Fusiformis legeri Grassé. (Compt. rend. Soc. Biol., Paris, *94*, 1926, 1014; Arch. Zool. Expér. et Gén., *65*, 1926, 467.) From the surface of the body of a flagellate (*Polymastix legeri*) and in the intestine of diplopods.

Fusiformis lophomonadis Grassé. (Compt. rend. Soc. Biol., Paris, *94*, 1926, 1015; Arch. Zool. Expér. et Gén., *65*, 1926, 468.) From the surface of the body of a flagellate (*Lophomonas striata*) and in the intestine of cockroaches.

Fusiformis melolonthae Grassé. (Compt. rend. Soc. Biol., Paris, *94*, 1926, 1014; Arch. Zool. Expér. et Gén., *65*, 1926, 465.) From the surface of the body of a flagellate (*Polymastix melolonthae*) and in the intestine of larvae of beetles and tipulids.

Gluconoacetobacter cerinus Takahashi and Asai. (Cent. f. Bakt., II Abt., *93*, 1936, 252.) From fruits.

Gluconoacetobacter liquefaciens Takahashi and Asai, *loc. cit.* From fruits.

Gluconoacetobacter roseus Takahashi and Asai. (*Bacterium industrium* var. *hoshigaki* Takahashi and Asai, Cent. f. Bakt., II Abt., *82*, 1930, 400; *Bacterium hoshigaki* var. *glucuronicum I* Takahashi and Asai, *ibid.*, *87*, 1933, 385; Takahashi and Asai, *ibid.*, *93*, 1936, 252.) From dried persimmons (hoshigaki).

Gluconobacter liquefaciens Asai. (Jour. Agr. Chem. Soc. Japan, *10*, 1934,

621 and *11*, 1935, 50; see Cent. f. Bakt., II Abt., *93*, 1936, 248.) From fruits.

Jodococcus magnus Miller. (Deutsche med. Wchnschr., *14*, 1888, 612.) From the mouth. The type species of the genus *Jodococcus* (syn. *Iodococcus*) Miller.

Jodococcus parvus Miller (*ibid.*, 612). From the mouth.

Lactobacillus bulgaricus Holland syn. *Bacterium bulgaricum* Buchanan and Hammer, Iowa Sta. Agr. Exp. Sta., Res. Bull. 22, 1915, 250.

Lactobacillus buchneri Bergey et al. syn. *Ulvina buchneri* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 75.

Lactobacillus delbrueckii Beijerinck syn. *Ulvina delbruecki* Pribram, *loc. cit.*, 75; *Plocamobacterium delbruecki* Pribram, *ibid.*, 77.

Lactobacillus helveticus Holland syn. *Plocamobacterium casei* Pribram, *loc. cit.*, 77; *Plocamobacterium helveticum* Pribram, *ibid.*, 78.

Lactobacillus pastorianus Bergey et al. syn. *Plocamobacterium pastorianum* Pribram, *loc. cit.*, 78.

Lactobacillus pentoaceticus Fred, Peterson and Davenport syn. *Plocamobacterium pentoaceticum* Pribram, *loc. cit.*, 78.

Lactobacillus plantarum Holland syn. *Ulvina cucumeris fermentati* Pribram, *loc. cit.*, 75.

Lactobacillus taette Olsen-Sopp. (Cent. f. Bakt., II Abt., *33*, 1912, 14.) From ropy milk.

Leptotrichia Trevisan partial syn. *Leucothrix* Oersted, De regionibus marinis, 1844, 44.

Listeria monocytogenes Pirie syn. *Brucella monocytogenes* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 68.

Mammococcus gorini. (Quoted from L. Gorini, Enzymologia, *10*, 1942, 102.) From the udder.

Micrococcus afermentans Castellani. (Proc. Soc. Exp. Biol. and Med., *25*, 1928, 536; also see Jour. Trop. Med. and Hyg., *35*, 1932, 372.) From an ulcerative lesion of the skin.

Micrococcus albus var. *maltigenes* Dumais and Albert. (Quebec Laitier, *5* (2), 1946, 19.) From Richelieu cheese. Regarded as an important ripening agent.

Micrococcus aquatilis Vaughan. (Vaughan, Amer. Jour. Med. Sci., *104*, 1892, 190; not *Micrococcus aquatilis* Chester, Man. Determ. Bact., 1901, 88; not *Micrococcus aquatilis* Bolton, Ztschr. f. Hyg., *1*, 1886, 94.) From water.

Micrococcus aquatilis albissimus von Rigler. (Hyg. Rund., *12*, 1902, 482.) From bottled mineral waters.

Micrococcus aquatilis albus Vaughan. (Vaughan, Amer. Jour. Med. Sci., *104*, 1892, 182; not *Micrococcus aquatilis albus* Toporoff, Cent. f. Bakt., *13*, 1893, 487.) From water.

Micrococcus aquatilis magnus Vaughan. (Amer. Jour. Med. Sci., *104*, 1892, 182.) From water.

Micrococcus aquivivus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 275.) From sea water.

Micrococcus cyaneus (Schroeter) Cohn syn. *Bacterium cyaneus* White, U. S. D.A., Bur. Entomol. Tech. Ser. Bull. 14, 1906, 16.

Micrococcus enteroideus Castellani. (Proc. Soc. Exp. Biol. and Med., *25*, 1928, 536; also see Jour. Trop. Med. and Hyg., *35*, 1932, 372.) From feces.

Micrococcus euryhalis ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 255.) From sea water.

Micrococcus griseus Winter syn. *Bacillus griseus* Trevisan, I generi e le specie delle Batteriacee, 1889, 18.

Micrococcus himonoi Kimata. (Cent. f. Bakt., II Abt., *105*, 1942, 116.) From spoiled semi-dried fishes (*Scomber japonicus* and *Trachurus japonicus*). Resembles *Micrococcus caseolyticus* and *M. mucofaciens*.

Micrococcus infimus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 262.) From marine bottom deposits.

Micrococcus laevulosinertis Castellani. (Proc. Soc. Exp. Biol. and Med., *25*, 1928, 536; also see Jour. Trop. Med. and Hyg., *35*, 1932, 372.) From a case of stomatitis.

Micrococcus maripuniceus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 264.) Sessile form found on slides submerged in sea water.

Micrococcus metentericus Castellani. (Quoted from Jour. Trop. Med. and Hyg., *35*, 1932, 372.) From case of ulcerative colitis.

Micrococcus moricolor Holmes and Wilson. (Jour. Bact., *49*, 1945, 311.) From contaminated wounds. Produces a mulberry pigment on potato.

Micrococcus myceticus Castellani. (Arch. Dermat. and Syphil., *18*, 1928, 857.) From cases of pseudomycosis.

Micrococcus nexifer Miller. (Miller, Die Mikroorganismen der Mundhöhle, Leipzig, 1889, 65.) From the mouth. Probably *Streptococcus brevis* according to Goadby (Mycology of the Mouth, London, 1903, 60).

Micrococcus putatus Ravenel. (Mem. Nat. Acad. Sci., *8*, 1896, 21.) From soil.

Micrococcus putneus Castellani. (Quoted from Jour. Trop. Med. and Hyg., *35*, 1932, 372.) From a case of glossitis.

Micrococcus rhodochrous Migula syn. *Bacillus rhodochrous* Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 362; *Bacterium rhodochrous* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 116.) Dyar had the original *Micrococcus rhodochrous* culture from Kràl and felt as have others who have examined this culture that it is not a true *Micrococcus*.

Micrococcus sedentarius ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 260.) Sessile form found on slides submerged in sea water.

Micrococcus sedimenteus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 265.) Sessile form found on slides submerged in sea water and in marine mud.

Micrococcus visicidus Castellani. (Proc. Soc. Exp. Biol. and Med., *25*, 1928, 536; also see Jour. Trop. Med. and Hyg., *35*, 1932, 372.) From an inflamed upper lip.

Microspira vacillans Gicklhorn. (Cent. f. Bakt., II Abt., *50*, 1920, 422.) From the pool in the Botanical Garden, Univ. Graz, Austria. Contains grains of sulfur.

Neisseria babesi Trevisan. (Bactérie de l'hémoglobinurie du boeuf, Babes, 1888; Trevisan, I generi e le specie delle Batteriacee, 1889, 32.)

Neisseria lutea (Adametz) Trevisan. (*Diplococcus luteus* Adametz, 1887; Trevisan, I generi e le specie delle Batteriacee, 1889, 32.)

Neisseria micheli Trevisan. (Trachomcoccus, Michel, 1886; Trevisan, I generi e le specie delle Batteriacee, 1889, 32.)

Neisseria pharyngis syn. *Micrococcus pharyngis* Cruikshank and Cruikshank, Med. Res. Council Syst. of Bact., *8*, 1931, 349.

Pacinia decipiens Trevisan. (*Spirillum* aus der Luft, Babes, Ztschr. f. Hyg., *5*, 1888, 183; Trevisan, I generi e le specie delle Batteriacee, 1889, 24.) From the air.

Pacinia rabida Trevisan. (Spirillum bei Rabies, Babes, Ztschr. f. Hyg., *5*, 1888, 181; Trevisan, I generi e le specie delle Batteriacee, 1889, 23.)

Pectobacterium delphinii Waldee. (Ark, Phytopath., *28*, 1938, 281; Waldee, Iowa State Coll. Jour. Sci., *19*, 1945, 471.) Causes larkspur bacterial blight.

Phytomonas asplenii Ark and Tompkins. (Phytopath., *36*, 1946, 760.) Causes leaf blight of bird's nest fern.

Phytomonas maculifolium-gardeniae

Ark. (Phytopath., *36*, 1946, 867.) From gardenia (*Gardenia jasminoides*). A xanthomonad.

Phytomonas syringae populans Smith. (Jour. Agr. Res., *68*, 1944, 269.) Considered the cause of blister spot, a disease of apple.

Phytomonas washingtoniae Pine. (Phytopath., *33*, 1943, 1203.) From the Washington palm, *Washingtonia filifera*. A pseudomonad.

Pneumococcus flavescens Arloing. (Compt. rend. Acad. Sci., *109*, 1889, 428 and 459.) From lesions of cattle having peripneumonia.

Pneumococcus gutta cerei Arloing, *loc. cit.* From lesions of cattle having peripneumonia.

Pneumococcus lichnoides Arloing, *loc. cit.* From lesions of cattle having peripneumonia.

Pseudomonas aestumarina ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 269.) A marine sedentary organism.

Pseudomonas allii (Griffiths) Migula syn. *Bacillus allii* Sternberg, Man. of Bact., 1893, 629.

Pseudomonas ambigua (Wright) Chester syn. *Bacterium ambiguus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 71.

Pseudomonas atlantica Humm. (Duke Univ. Marine Lab., North Carolina, Bull. 3, 1946, 58.) From seaweed (*Gracilaria blodgettii*) and beach sand. Digests agar.

Pseudomonas aurea Migula syn. *Bacterium fluorescens aureus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 109.

Pseudomonas azotogena ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 260.) From sea water and marine mud.

Pseudomonas beaufortensis Humm (*loc. cit.*, 58). From seawater, bottom mud and on algae. Digests agar.

Pseudomonas berolinensis Migula. (Indigoblauer Bacillus, Claessen, Cent. f. Bakt., *7*, 1890, 13; *Bacillus berolinensis indicus* Germano, Cent. f. Bakt., *12*, 1892, 517; *Bacillus indigoferus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *2*, 1894, 16, not indicated as being the same as *Bacillus indigoferus* Voges, Cent. f. Bakt., *14*, 1893, 307; *Bacillus indigonaceus* Schneider, Arb. bakt. Inst. Karlsruhe, *1*, Heft 2, 1894, 228; Migula, in Engler and Prantl, Die natürl. Pflanzenfam., *1*, 1a, 1895, 29; *Bacterium indigonaceum* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 267; *Bacterium berolinensis indicus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 118.) From Spree River water.

Pseudomonas butyri Migula syn. *Bacterium butyri fluorescens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 120.

Pseudomonas centrifugans (Wright) Chester. (*Bacillus centrifugans* Wright, Mem. Nat. Acad. Sci., *7*, 1895, 462; *Bacterium centrifugans* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 95; Chester, Man. Determ. Bact., 1901, 312.) From water.

Pseudomonas coadunata Chester syn. *Bacterium coadunatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 90.

Pseudomonas coenobios ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 272.) From film of marine fouling organisms.

Pseudomonas cohaerea (Wright) Chester, not *Bacillus cohaerens* Gottheil, Cent. f. Bakt., II Abt., *7*, 1901, 458; *Bacterium cohaereus* (sic) Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 93.

Pseudomonas coli communis Conn, Esten and Stocking. (Storrs Agri. Exp. Sta., Conn., 18th Ann. Rept. for 1906, 186.) From cheddar cheese. Like *Bacillus coli communis* except that it has a single, long flagellum.

Pseudomonas convexa Chester syn. *Bacterium fluorescens convexus* Chester,

Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 123.

Pseudomonas corallina Humm (*loc. cit.*, 59). From marine algae of all common species at Beaufort, Nor. Car. Digests agar.

Pseudomonas delabens (Wright) Chester syn. *Bacterium delabens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 97.

Pseudomonas eisenbergii Migula syn. *Bacterium fluorescens non-liquefaciens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 124.

Pseudomonas elongata Humm (*loc. cit.*, 60). From intertidal sand, Atlantic Beach, Nor. Car. Digests agar.

Pseudomonas enalia ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 254.) From sea water and marine mud.

Pseudomonas fairmountensis (Wright) Chester syn. *Bacterium fairmountensis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 90.

Pseudomonas felthami ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 267.) From marine mud.

Pseudomonas fimbriata (Wright) Chester syn. *Bacterium fimbriatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 95.

Pseudomonas floridana Humm (*loc. cit.*, 60). From algae and beach sand at Miami, Fla., and Beaufort, Nor. Car. Digests agar.

Pseudomonas fluorescens Migula syn. *Bacterium fluorescens liquefaciens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 120.

Pseudomonas foliacea Chester syn. *Bacterium fluorescens foliaceus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 122.

Pseudomonas geniculatus (Wright) Chester. *Bacillus geniculatus* Wright; not *Bacillus geniculatus* DeBary, Inaug. Diss., Strassburg, Leipzig, 1885; not *Bacillus geniculatus* Trevisan, I generi e le specie delle Batteriacee, 1889, 16; syn. *Bacterium geniculatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 95.

Pseudomonas humicola Bersteyn. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 97.) From soil.

Pseudomonas hypothermis ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 276.) From marine bottom deposits.

Pseudomonas incognita Chester syn. *Bacterium fluorescens incognitus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 122.

Pseudomonas indoloxidans Gray. (Proc. Roy. Soc. London, B, *102*, 1928, 263.) From soil from Italian Tyrol.

Pseudomonas indigoferus (Voges) Migula. (*Bacillus indigoferus* Voges, Cent. f. Bakt., *14*, 1893, 307; *Bacterium indigoferus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 118; Migula, Syst. d. Bakt., *2*, 1900, 950.) From Kiel tap water (Voges); from Delft ditch water, mud and garden soil (Elazari-Volcani, Arch. f. Mikrobiol., *10*, 1939, 357). Some authors regard Voges' organism as identical with Claessen's indigo blue bacillus, see *Pseudomonas berolinensis*.

Pseudomonas indigoferus var. *immobilis* Elazari-Volcani. (Arch. f. Mikrobiol., *10*, 1939, 350.) From ditch mud. See Lehmann and Neumann (Bakt. Diag., 1 Aufl., *2*, 1896, 267) who also had a non-motile strain (*Bacterium indigonaceum*) from Kràl which they considered identical with Claessen's indigo blue bacillus.

Pseudomonas inertia Humm (*loc. cit.*, 61). From intertidal sand, Atlantic Beach, Nor. Car. Digests agar.

Pseudomonas iris Migula syn. *Bacillus fluorescens crassus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 294; *Bacterium fluorescens crassus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 134; *Bacterium iris* Chester, *idem*, 137.) From sputum.

Pseudomonas jaegeri Migula syn. *Bac-*

terium proteus fluorescens Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 119; and *Bacillus urinae* Chester, Man. Determ. Bact., 1901, 263.

Pseudomonas javanica (Eijkmann) Migula syn. *Bacterium javaniensis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 111.

Pseudomonas liquida Chester. (*Bacillus liquidus* Frankland and Frankland, Ztschr. f. Hyg., *6*, 1889, 382; Chester, Man. Determ. Bact., 1901, 311; *Achromobacter liquidum* Bergey et al., Manual, 1st ed., 1923, 145.) From water. Originally described merely as motile; Chester recognizes the species as polar flagellate and lists *Bacillus liquefaciens communis* Sternberg and *Bacillus aquatilis communis* Kruse as synonyms.

Pseudomonas longa Migula syn. *Bacterium fluorescens longus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 124.

Pseudomonas macroselmis Migula syn. *Bacillus fluorescens putidus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 124.

Pseudomonas marinopersica ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 275.) From marine bottom deposits.

Pseudomonas melochlora (Winkler and Schrötter) Migula syn. *Bacterium melochlorus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 120; see abst. in Cent. f. Bakt., *9*, 1891, 700.

Pseudomonas membranula ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 270.) Sessile form found on slide submerged in sea.

Pseudomonas minutissima Migula syn. *Bacterium fluorescens minutissimus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 120.

Pseudomonas monadiformis (Kruse) Chester syn. *Bacterium monadiformis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 69; *Bacterium coli mobilis* Chester, *ibid.*, 69.

Pseudomonas multistriata (Wright) Chester syn. *Bacterium multistriatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 90.

Pseudomonas nebulosa (Wright) Chester syn. *Bacterium nebulosus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 93.

Pseudomonas neritica ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 255.) From sea water and marine mud.

Pseudomonas nexibilis (Wright) Chester syn. *Bacterium nexibilis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 74.

Pseudomonas obscura ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 274.) From marine bottom deposits.

Pseudomonas oceanica ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 266.) From marine mud.

Pseudomonas ochracea (Zimmermann) Chester syn. *Bacterium ochraceus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 104.

Pseudomonas ovalis Chester syn. *Bacterium fluorescens ovalis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 123.

Pseudomonas pallescens Migula syn. *Bacterium viridis pallescens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 124.

Pseudomonas perfectomarinus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 277.) From sea water and marine mud.

Pseudomonas periphyta ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 276.) Sessile form found in film of marine fouling organisms.

Pseudomonas phosphorescens (Fisher) Bergey et al. syn. *Pasteurella phosphorescens* Trevisan, I generi e le specie delle Batteriacee, 1889, 21; *Bacillus phosphorescens indicus* Eisenberg, Bakt.

Diag., 3 Aufl., 1891, 123; *Vibrio indicus* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 341; *Bacterium phosphorescens indicus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 120; *Photobacter indicum* Beijerinck, Proc. Sect. Sci., Kon. Akad. v. Wetensch., Amsterdam, *3*, 1900, 352; *Microspira phosphorescens* Chester, Man. Determ. Bact., 1901, 333; *Bacillus indicus* Beijerinck, Folia Mikrobiologica, Delft, I, 1912, 1. Beijerinck (*loc. cit.*, 1900) discusses two variants of this species: *Photobacter indicum* var. *obscurum* and *Photobacter indicum* var. *parvum*. Later, Beijerinck (*loc. cit.*, 1912), in discussing mutants of this species, proposes the species names *Bacillus indicus parvus*, *Bacillus indicus semiobscurus* and *Bacillus indicus obscurus*.

Pseudomonas piscova Hanzawa and Takeda. (Jozogaku Zasshi, Osaka, Japan (Jour. of Zymology), *9*, 1931, 571; quoted from Takeda, Cent. f. Bakt., II Abt., *94*, 1936, 46.) From diseased salmon eggs.

Pseudomonas pleomorpha ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 275.) From marine bottom deposits.

Pseudomonas pullulans (Wright) Chester syn. *Bacterium pullulans* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 105.

Pseudomonas puris Patrick and Werkman. (Proc. Iowa Acad. Sci., *37*, 1930, 57.) From a typhoid-like infection of snakes.

Pseudomonas ribicola Bohn. (Jour. Agr. Res., *73*, 1946, 288.) From the native currant, *Ribes aureum*.

Pseudomonas riboflavinus Foster. (Jour. Bact., *47*, 1944, 30.) Oxidizes riboflavin to lumichrome. From riboflavin-rich soil.

Pseudomonas roseola Humm (*loc. cit.*, 62). From intertidal sand, Atlantic Beach, Nor. Car. Digests agar.

Pseudomonas rugosa (Wright) Chester syn. *Bacterium rugosus* Chester. Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 122.

Pseudomonas schuylkilliensis Chester syn. *Bacterium fluorescens schuylkilliensis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 119.

Pseudomonas scissa (Frankland and Frankland) Migula syn. *Bacterium scissus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 143.

Pseudomonas sessilis ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 259.) Sessile form found on solid surfaces submerged in the sea.

Pseudomonas sinuosa (Wright) Chester syn. *Bacterium sinuosus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 69.

Pseudomonas smaragdina Migula syn. *Bacterium smaragdino foetidus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 119; and *Bacillus smaragdinus* Chester, Man. Determ. Bact., 1901, 263.

Pseudomonas sterotropis ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 272.) From a film of marine fouling organisms.

Pseudomonas striata Chester syn. *Bacterium striatus viridis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 123.

Pseudomonas syncyanea Migula syn. *Bacterium syncyanus* (sic) Schroeter, Beitr. z. Biol. d. Pflanz., *1*, Heft 2, 1872, 126 and *Bacterium cyanogenum* Zopf, Die Spaltpilze, 2 Aufl., 1884, 50; may be in 1 Aufl.

Pseudomonas synxantha (Ehrenberg) Holland. (*Vibrio synxanthus* Ehrenberg, Verhandl. d. Berl. Akad., 1840, 202; *Vibrio xanthogenes* Fuchs, Magazin f. d. ges. Tierheilk., I, 1841, 193; *Bacterium xanthinum* Schroeter, in Cohn, Beiträge z. Biol. d. Pflanzen, *1*, Heft 2, 1872, 120; *Bacillus synxanthus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 290; *Flavobacterium synxanthum* Bergey et al., Manual, 1st ed., 1923, 102; Holland, Jour. Bact., *5*, 1920, 220.) Bergey et al.

(Manual, 1st ed., 1923, 102) give *Bacterium xanthogenes* as a synonym. From milk and cream. Polar flagellate (Hammer, personal communication). See Hammer, Res. Bul. 20, Iowa Agr. Exp. Sta., 1915, for a description of this organism.

Pseudomonas tenuis Migula syn. *Bacterium fluorescens tenuis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 124.

Pseudomonas turcosa Migula syn. Türkisfarbener *Bacillus*, Tataroff, Inaug. Diss., Dorpat, 1891, 52.

Pseudomonas vadosa ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 263.) From sea water and marine bottom deposits.

Pseudomonas vendrelli Tobie. (*Pseudomonas vendralli* (*sic*), mentioned by Farrell and Wolff, Jour. Ind. and Eng. Chem., *33*, 1941, 1186; U. S. Patent 2,227,716, Mar. 1942, issued to Lockwood et al.; *Bacillus vendrelli* Lasseur, Dupaix-Lasseur and Melcion, Travaux Lab. Microbiol. Fac. Pharm. Nancy, Fasc. 13, 1942–43–44, 1944, 293.) Isolated by W. C. Tobie in 1938 from well near Ponce, Puerto Rico owned by Mr. Vendrell (Tobie, Jour. Bact., *52*, 1946, 685). Presumably *Pseudomonas aeruginosa.*

Pseudomonas virescens (Frick) Migula syn. *Bacterium virescens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 124.

Pseudomonas viscosa (Frankland and Frankland) Migula syn. *Bacterium viscosus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 145; not *Bacterium viscosum* Weldin and Levine, Abst. Bact., *7*, 1923, 16.

Pseudomonas xanthochrus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 279.) From marine bottom deposits.

Ramibacterium alactolyticum Prévot and Taffanel. (Ann. Inst. Past., *68*, 1942, 259.) From an osteophlegmon of the maxillary bone.

Salmonella atherton Ferris, Hertzberg and Atkinson. (Med. Jour. Australia, *32*, 1945, 368.) From 29 cases of gastroenteritis in an army hospital.

Salmonella typhosa (Zopf) White syn. *Bacillus typhicus* Cabral and Da Rocha, I. Trabalhos do Cabinette de Microbiologia; abst. in Ann. de Micrographie, *2*, 1889–1890, 295.

Sarcina pelagia ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 279.) From sea water and marine bottom deposits.

Serratia fuchsina Bergey et al. syn. *Proteus fuchsinus* Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 73.

Serratia indica (Eisenberg) Bergey et al. syn *Bacillus indicus ruber* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 285; *Bacterium indicum* Crookshank, Manual, 1887, 240.

Spirillum parvum Esmarch. (Cent. f. Bakt., I Abt., Orig., *32*, 1902, 565; also see Zettnow, *ibid.*, *78*, 1916, 1.) From decaying organic matter.

Spirillum sputigenum Flügge. (Lewis, Lancet, Sept. 20, 1884; Flügge, Die Mikroorganismen, 2 Aufl., 1886, 387; *Pacinia lewisi* Trevisan, I generi e le specie delle Batteriacee, 1889, 24.) From sputum.

Staphylococcus activus Prévot and Taffanel. (Ann. Inst. Past., *71*, 1945, 102.) From puerperal septicemia. Anaerobic.

Staphylococcus citreus duodenalis Gessner. (Arch. f. Hyg., *9*, 1889, 136.) From the human duodenum.

Staphylococcus magnus Black. (Trans. Ill. State Dental Soc., *22*, 1886, 188.) From the mouth.

Staphylococcus medius Black. (Trans. Ill. State Dental Soc., *22*, 1886, 190.) From the mouth.

Staphylococcus pyogenes bovis Lucet. (Ann. Inst. Past., *7*, 1893, 327.) From bovine abscesses.

Staphylococcus viscosus Goadby.

(Mycology of the mouth, London, 1903, 172.) From the mouth.

Streptobacterium dextranicum Perquin. (Jour. Microbiol. and Serol., *6*, 1940, 226.) Produces slime from sucrose solutions.

Streptococcus aquatilis Vaughan. (Amer. Jour. Med. Sci., *104*, 1892, 184.) From water.

Streptococcus liquefaciens Frankland and Frankland. (Phil. Trans. Roy. Soc. London, *178*, B, 1888, 264.) From air. After the section covering *Streptococcus liquefaciens* Sternberg *emend.* Orla-Jensen was in page proof, it was discovered that Frankland and Frankland had discovered and named a liquefying streptococcus earlier than Sternberg. The Franklands described this species as producing a yellow pigment.

Streptococcus pyogenes duodenalis Gessner. (Arch. f. Hyg., *9*, 1889, 132.) From the human duodenum.

Streptococcus taette (Olsen-Sopp) Buchanan and Hammer. (*Bacterium lactis longi* Troili-Petersson, Ztschr. f. Hyg., *32*, 1899, 361 and Milchzeitung, *28*, 1899, 438; *Streptobacillus taette* Olsen-Sopp, Cent. f. Bakt., II Abt., *33*, 1912, 9; Buchanan and Hammer, Iowa Sta. Coll. Agr. Exp. Sta., Res. Bull. 22, 1915, 277.) Probably the characteristic organism of Swedish ropy milk. Olsen-Sopp (*loc. cit.*) misquotes Troili-Petersson's name as *Bacillus acidi lactis longus* (see Troili-Petersson, Cent. f. Bakt., II Abt., *38*, 1913, 1).

Thiospira agilissima (Gicklhorn) Bavendamm. (*Spirillum agilissimum* Gicklhorn, Cent. f. Bakt., II Abt., *50*, 1920, 418; Bavendamm, Die farblosen und roten Schwefelbakterien, Pflanzenforschung, Heft 2, 1924, 116.) From the pond in the Annen Castle Park, Graz, Austria. Contains grains of sulfur.

Thiospira elongata Perfiljev. (Ber. d. Sapropel Komm. Petrograd, 1923, 56.) From mud containing H_2S.

Thiospira propera Hama. (Jour. Sci. Hiroshima Univ., Ser. B, Bot., *1*, 1933, 157; abst. in Cent. f. Bakt., II Abt., *91*, 1934, 200.)

Thiospira sulfurica Issatchenko. (Biological observations on the sulfur bacteria (Russian), about 1927, 16 pp.)

Vibrio adaptatus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 258.) From sea water and marine sediments.

Vibrio agarlyticus Cataldi. (Rev. d. Inst. Bact. (D.N.H.), Buenos Aires, *9*, 1940, 375.) From activated sludge. Digests agar.

Vibrio albensis Lehmann and Neumann syn. *Vibrio dunbari* Holland, Jour. Bact., *5*, 1920, 226; probably *Vibrio phosphorescens* Jermoljewa, Cent. f. Bakt., I Abt., Orig., *100*, 1926, 170; not *Vibrio phosphorescens* Holland, *loc. cit.*

Vibrio algosus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 257.) Associated with marine kelp.

Vibrio amphibolus Trevisan. (Babes, Ztschr. f. Hyg., *5*, 1888, 183; Trevisan, I generi e le specie delle Batteriacee, 1889, 23.) Anaerobe.

Vibrio avidus Humm. (Duke Univ. Marine Lab., North Carolina, Bull. 3, 1946, 54.) From intertidal sand, Beaufort, North Carolina. Digests agar.

Vibrio choleroides α and β Bujwid syn. *Bacterium choleroides* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 131.

Vibrio costicolus Smith and *Vibrio costicolus* var. *liquefaciens* Smith. (Roy. Soc. Queensland, Proc. for 1937, *49*, 1938, 29 and 32.) From tainted ribs of bacon and tank brines in bacon factories. Active growth in 4 to 15 per cent brines.

Vibrio euprima, *Vibrio yasakii*, *Coccobacillus tolega* and *Coccobacillus sepiola* Majima, Sci-i Kwai- Med. Jour. *50*, 1931, 41–67; see Warren, Jour. Bact., *49*, 1945, 548.) Phosphorescent bacteria.

Vibrio fortis Humm (*loc. cit.*, 55). From seaweed (*Gracilaria confervoides*). Digests agar.

Vibrio frequens Humm (*loc. cit.*, 56). From marine algae (*Cladophoropsis*, *Laurencia poitei*, etc.) Digests agar.

Vibrio halonitrificans Smith. (Roy. Soc. Queensland, Proc. for 1937, *49*, 1938, 29.) From tank brines in bacon factories. Active growth in 4 to 10 per cent brines.

Vibrio haloplanktis ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 261.) Sessile form found associated with marine phytoplankton.

Vibrio hyphalus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 277.) From marine bottom deposits.

Vibrio marinagilis ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 264.) From sea water and marine mud.

Vibrio marinoflavus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 258.) From sea water.

Vibrio marinofulvus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 262.) From sea water.

Vibrio marinopraesens ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 256.) From sea water.

Vibrio marinovulgaris ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 261.) From sea water.

Vibrio notus Humm (*loc. cit.*, 56). From intertidal sand, Atlantic Beach, North Carolina. Digests agar.

Vibrio perimastrix Alarie. (Alarie, Thesis, MacDonald Coll. McGill Univ., 1945; see Perlin and Michaelis, Sci., *103*, 1946, 673.) Will decompose cellulose only in presence of CO_2.

Vibrio phytoplanktis ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 261.) From sea water and marine phytoplankton.

Vibrio pieris Paillot. (Compt. rend. Soc. Biol., Paris, *94*, 1926, 68.) From caterpillars of the cabbage butterfly (*Pieris brassicae*) which had been parasitized by larvae of *Apanteles glomeratus*.

Vibrio ponticus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 259.) From sea water.

Vibrio rumpel Lode. (Cent. f. Bakt., I Abt., Orig., *35*, 1903, 526; see Ballner, Cent. f. Bakt., II Abt., *19*, 1907, 572.) From water. Phosphorescent.

Vibrio stanieri Humm (*loc. cit.*, 57). From seaweed (*Acanthophora spicifera*), Miami, Fla. Digests agar.

Vibrio turbidus Humm (*loc. cit.*, 57). From seaweed (*Gracilaria confervoides*). Digests agar.

Vibrio viridans Miller. (Quoted from Miller, Microorganisms of Human Mouth, Phila., 1890, 85; see Miller, Die Mikroorganismen der Mundhöhle, Leipzig, 1889.) From the mouth.

Xanthomonas translucens var. *phleipratensis* Wallin and Reddy. (Phytopathology, *35*, 1945, 939.) The cause of a bacterial streak disease on timothy grass (*Phleum pratense*).

Xanthomonas vignicola Burkholder. (Phytopath., *34*, 1944, 431.) From cowpea, *Vigna sinensis*.

Yersinia van Loghem (Ann. Past. Inst., *72*, 1946, 975), a genus proposed to include *Pasteurella pestis* and *P. pseudotuberculosis*.

Ein neuer für Thiere path. Mikroorg. aus dem Sputum eines Pneumoniekranken, Bunzel and Federn, Arch. f. Hyg., *19*, 1893; 326; *Bacillus dubius pneumoniae* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 419; *Bacterium subpneumonicum* Migula, Syst. d. Bakt., *2*, 1900, 376; *Bacterium dubium* Chester, Man. Determ. Bact., 1901, 142. From the sputum of a pneumonia patient.

FAMILY XIII. BACILLACEAE FISCHER.*

(Jahrb. f. wiss. Bot., *27*, 1895, 139.)

Rod-shaped cells, capable of producing spores, either with peritrichous flagella or non-motile; monotrichous flagellation has been reported but is doubtful. Endospores are cylindrical, ellipsoidal or spherical, and are located in the center of the cell, sub-terminally or terminally. Sporangia do not differ from the vegetative cells except when bulged by spores larger than the cell diameter. Such sporangia are spindle-shaped when spores are central, or wedge- or drumstick-shaped when spores are terminal. Usually Gram-positive. Pigment formation is rare. Aerobic, microaerophilic or anaerobic. Gelatin is frequently liquefied. Sugars are generally fermented, sometimes with the formation of visible gas. Some species are thermophilic, i.e., will grow readily at 55°C. Mostly saprophytes, commonly found in soil. A few are animal, especially insect, parasites or pathogens.

Key to the genera of family **Bacillaceae.**

I. Aerobic; catalase positive.
Genus I. *Bacillus*, p. 705.

II. Anaerobic or microaerophilic; catalase not known to be produced.
Genus II. *Clostridium*, p. 763.

INTRODUCTION TO THE GENUS BACILLUS.

In the fifth edition of the MANUAL, the late F. D. Chester stated: "It is difficult to offer a rational system of classification for the described forms of the genus *Bacillus* because of the incompleteness of the data". He prepared a splendid review of the literature but naturally could not supply the data that were missing. He stated further that "The majority of the so-called species in the genus have been imperfectly presented, . . . the net result being that there are comparatively few clearly and definitely described species among the many herein recorded. The development of a better knowledge will be a work of the future". He then discussed the type of work that should be done. A reading of his statement is recommended to anyone contemplating naming a new species.

During the past few years, the writer with the assistance of Francis E. Clark and Ruth E. Gordon has made a study of the genus *Bacillus* along the lines indicated by Chester. Representative cultures have been obtained from various laboratories, institutions, and private collections. Special mention should be made of the private collection of Prof. J. R. Porter, now at the Iowa State University. It contained about 200 named species and was invaluable for the work. As a result of this study, it appears that many species have been differentiated by such simple characters as mucoid, folded, adherent or rhizoid growth, pigment production, the fermentation of a specific carbohydrate, etc. Others have been grouped because of some special physiological activity such as the decomposition of calcium n-butyrate, xylan, cellulose, etc. Chester rightly considered that these physiological groups had no taxonomic value.

Species have been characterized upon a broad basis in the present arrangement on the assumption that one species should not dissociate into another species. Since certain characters are more stable than others, these have been used to establish a

---

* Revised by Mr. Nathan R. Smith, U. S. Bureau of Plant Industry Station, Beltsville, Maryland (*Bacillus*), August, 1943, and Prof. R. S. Spray, School of Medicine, West Virginia University, Morgantown, West Virginia (*Clostridium*), May, 1942.

species pattern. This has reduced the number of species of the mesophilic members of the genus from many poorly defined organisms to a few well characterized and delimited species. Intermediates occur between related species and have been treated as such. The report on which this arrangement is based has recently been published by Smith, Gordon and Clark (U. S. Dept. Agr. Misc. Pub. No. 559, 1946, 112 pp.).

Some workers may think that the cut in the number of species has been too drastic and that certain organisms listed as varieties, morphotypes, or biotypes should be retained as species. This would not be consistent with the newer knowledge of bacteriology that has been developed during the past two decades. No doubt other species occur in nature that are not included herein. But before jumping to the conclusion that a culture *is* a new species, closely related organisms as well as the isolate should be studied along the lines given by Chester in the fifth edition of the MANUAL.

The production of indole and the formation of H_2S have been omitted from the descriptions because these characters have no taxonomic value. Certain other properties, such as colony form, character of the growth on slants, in litmus milk, etc., have a very limited value. They are included for the sake of completeness.

Genus I. Bacillus *Cohn.**

(Beiträge z. Biol. d. Pflanzen, *1*, Heft 2, 1872, 146 and 175.) From Latin *bacillum*, a small stick.

forming a pellicle on broth. Usually oxidize carbohydrates or proteins more or less completely, often producing slight acidity, without pronounced accumulation of characteristic products. Soil is the most common habitat.

The internationally accepted (Jour. Bact., *33*, 1937, 445) type species is *Bacillus subtilis* Cohn *emend.* Prazmowski.

Key to the species of genus **Bacillus.**

I. Mesophilic (good growth at 30°C), aerobic (sometimes also grow at low concentrations of oxygen).
  A. Spores ellipsoidal to cylindrical, central to terminal, walls thin. Sporangia not distinctly bulged. Gram-positive.
    1. Diameter of rods less than 0.9 micron. Cells from glucose or glycerol nutrient agar stain uniformly.
      a. Growth at pH 6.0. Acetylmethylcarbinol produced.
        b. Gelatin hydrolyzed (Frazier method). Acid from xylose or arabinose with ammoniacal nitrogen.
          c. Starch hydrolyzed. Nitrites produced from nitrates.
            1. *Bacillus subtilis.*
            d. Black pigment on carbohydrate media only.
              1a. *Bacillus subtilis* var. *aterrimus.*
            dd. Black pigment on tyrosin media only.
              1b. *Bacillus subtilis* var. *niger.*
          cc. Starch not hydrolyzed. Nitrites not formed from nitrates.
            2. *Bacillus pumilus.*
        bb. Gelatin not hydrolyzed. No acid from xylose or arabinose.
          3. *Bacillus coagulans.*
      aa. No growth at pH 6.0. Acetylmethylcarbinol not formed.
        b. Casein digested. Urease not formed.
          4. *Bacillus firmus.*
        bb. Casein not digested. Urease produced.
          5. *Bacillus lentus.*
    2. Diameter of rods 0.9 micron or more. Cells from glucose or glycerol nutrient agar appear vacuolated if lightly stained.
      a. Acid from xylose or arabinose with ammoniacal nitrogen. Acetylmethylcarbinol not produced.
        6. *Bacillus megatherium.*
      aa. No acid from xylose or arabinose. Acetylmethylcarbinol produced.
        b. Saprophytic, sometimes pathogenic but not causing anthrax; usually motile.
          c. Growth on agar not rhizoid.
            7. *Bacillus cereus.*
          cc. Rhizoid growth on agar; usually non-motile.
            7a. *Bacillus cereus* var. *mycoides.*
        bb. Pathogenic. Causative agent of anthrax; non-motile.
          8. *Bacillus anthracis.*
  B. Spores ellipsoidal, central to terminal, walls thick, remnants of sporangium often adhering. Sporangia distinctly bulged, spindle and racket forms. Gram-variable.
    1. Acid and gas from carbohydrates.
      a. Acetylmethylcarbinol produced. Crystalline dextrins not formed from starch.

9. *Bacillus polymyxa.*

aa. Acetylmethylcarbinol not produced. Crystalline dextrins formed from starch.

10. *Bacillus macerans.*

2. No visible gas from carbohydrates.

a. Saprophytic. Growth on ordinary media.

b. pH of glucose, proteose-peptone broth cultures less than 8.0. Citrates not used as source of carbon.

c. Starch hydrolyzed. Acid from sucrose with ammoniacal nitrogen.

d. Acid from xylose or arabinose with ammoniacal nitrogen. Acetylmethylcarbinol not formed.

11. *Bacillus circulans.*

dd. No acid from xylose or arabinose. Acetylmethylcarbinol produced.

12. *Bacillus alvei.*

cc. Starch not hydrolyzed. No acid from sucrose.

13. *Bacillus laterosporus.*

bb. pH of glucose, proteose-peptone broth cultures 8.0 or higher. Citrates used as source of carbon.

14. *Bacillus brevis.*

aa. Parasitic. No growth on ordinary media.

b. Cause of American foulbrood of honey bees.

15. *Bacillus larvae.*

bb. Cause of the milky disease of Japanese beetles (*Popillia japonica* Newm.).

Type A. 16. *Bacillus popilliae.*

Type B. 17. *Bacillus lentimorbus.*

C. Spores spherical, central to terminal. Sporangia definitely bulged, drumsticks and spindles. Carbohydrates not attacked. Gram-variable.

1. Growth on nutrient agar without urea or free ammonia.

a. Urease not formed.

18. *Bacillus sphaericus.*

aa. Urease produced.

18a. *Bacillus sphaericus* var. *fusiformis.*

2. No growth on nutrient agar without urea or free ammonia. Urease formed.

19. *Bacillus pasteurii.*

II. Thermophilic, optimum temperatures 55°C or above; slight if any growth at 37°C. Aerobic.*

A. Spores ellipsoidal to cylindrical, central to terminal; sporangia not distinctly bulged.

1. Diameter of rods less than 0.8 micron.

a. Gas from carbohydrates.

20. *Bacillus thermoamylolyticus.*

aa. No gas from carbohydrates.

---

* The data on the species of this group are so meager that it is not possible to offer a rational system of classification. Many of the characters used for separating the various species are probably as variable in this group as they have been found to be in the mesophilic group. Lacking a knowledge of the limits of variability and lacking other pertinent data, the present arrangement is regarded as temporary only.

b. Growth below 50°C.
c. Nitrites from nitrates, often with liberation of nitrogen gas.
21. *Bacillus kaustophilus.*
21a. *Bacillus pepo.*
cc. No nitrites from nitrates.
22. *Bacillus thermoindifferens.*
bb. No growth below 50°C.
23. *Bacillus thermodiastaticus.*
2. Diameter of rods greater than 0.8 micron.
a. Growth on nutrient agar.
b. Remnants of sporangium adherent.
24. *Bacillus cylindricus.*
bb. Remnants of sporangium not adherent.
25. *Bacillus robustus.*
25a. *Bacillus losanitchii.*
aa. No growth on nutrient agar.
26. *Bacillus calidolactis.*
B. Spores ellipsoidal to cylindrical, central to terminal; sporangia distinctly bulged.
1. Diameter of rods less than 0.9 micron.
a. Starch hydrolyzed.
b. Nitrites from nitrates, sometimes with liberation of nitrogen gas.
27. *Bacillus michaelisii.*
27a. *Bacillus lobatus.*
27b. *Bacillus thermononliquefaciens.*
bb. No nitrites from nitrates.
c. Action on cellulose not recorded.
28. *Bacillus thermotranslucens.*
28a. *Bacillus stearothermophilus.*
28b. *Bacillus aerothermophilus.*
cc. Cellulose hydrolyzed.
29. *Bacillus thermocellulolyticus.*
aa. Starch not hydrolyzed.
b. Nitrites from nitrates, sometimes with gaseous nitrogen.
c. Milk unchanged.
30. *Bacillus thermoalimentophilus.*
cc. Milk acid, coagulated.
31. *Bacillus thermoliquefaciens.*
2. Diameter of rods greater than 0.9 micron.
a. Starch hydrolyzed.
b. No nitrites from nitrates.
32. *Bacillus tostus.*
C. Spores spherical, central to terminal; sporangium not distinctly bulged.
33. *Bacillus viridulus.*

1. **Bacillus subtilis** Cohn *emend.* Prazmowski. (Cohn, Beitr. z. Biol. d. Pflanzen, *1*, Heft 2, 1872, 174; Heft 3, 1875, 188; *2*, Heft 2, 1876, 249; Prazmowski, Untersuchungen über die Entwicklungsgeschichte und Fermentwirkung einigen Bakterien-Arten. Inaug. Diss., Leipzig, 1880.) From Latin *subtilis*, thin, slender.

The identity of this species has been

the subject of some controversy owing to the indefiniteness of the original descriptions, to the distribution of cultures under the name *Bacillus subtilis* that were incorrectly identified, to variations in the forms of growth that may be observed, and to confusion with *Bacillus cereus*. In cases where *Bacillus subtilis* is said to be "anthrax-like," or "similar to the anthrax bacillus," it should be remembered that these terms apply to *Bacillus cereus* and not to *Bacillus subtilis*. Conn (Jour. Inf. Dis., *46*, 1930, 341) concluded that the so-called Marburg strain fitted the earliest recognizable description of this species which is that given by Prazmowski (*loc. cit.*), and his view was accepted after a study of cultures by the International Committee on Bacteriological Nomenclature (Jour. Bact., *33*, 1937, 445).

During the past two decades much progress has been made in the study of variations in the stages of growth of bacteria, the rough, smooth, mucoid, etc., and in the variability in physiology as well. From the recent work of Smith, Gordon, and Clark (*loc. cit.*) it appears that many species have been characterized on such simple grounds as growth folded, mucoid, adherent, colored, rhizoid, etc., all of which are subject to variation, either induced or spontaneous. The present arrangement of this species is the result of their work combined with data supplied by the work of Conn and others.

Species probably identical with or variants of *Bacillus subtilis:*

Bacillus geniculatus de Bary, Beitrag zur Kenntnis der niederen Organismen im Mageninhalt, Inaug. Diss., Strassburg, Leipzig, 1885; *Bacillus mesentericus fuscus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 321 (*Bacillus mesentericus* Trevisan, I generi e le specie delle Batteriacee, 1889, 19; not *Bacillus mesentericus* as interpreted by Chester, Del. Agr. Exp. Station 15th Ann. Report, 1903, 86; not *Bacillus mesentericus* as given by Lawrence and Ford, Jour. Bact., *1*, 1916, 295);* *Bacillus mesentericus vulgatus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 322 (*Bacillus vulgatus* Trevisan, I generi e le specie delle Batteriacee, 1889, 19); *Bacillus liodermos* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 323 (Bacillus No. X, Flügge, Ztschr. f. Hyg., *17*, 1894, 296; *Bacillus lactis* No. X, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 209; *Bacillus intermedius* Migula, Syst. d. London, *178*, B, 1887, 278 (not *Bacillus laevis* Distaso, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 444); *Tyrothrix tenuis* Duclaux, Ann. Inst. Nat. Agron., *4*, 1882, 23 (*Bacillus tenuis* Trevisan, I generi e le specie delle Batteriacee, 1889, 16); Kartoffelbacillus, Globig, Ztschr. f. Hyg., *3*, 1888, 294 (*Bacillus roseus* Trevisan, *loc. cit.*, 19; *Bacillus mesentericus ruber* Kruse, in Flügge, Die

*T. Gibson, University of Edinburgh (personal communication), has found that the European and supposedly the original strains of *Bacillus mesentericus* hydrolyze starch and reduce nitrates to nitrites, whereas the American strains are negative in both of these characters. Furthermore, the latter are usually smooth and when the rough stage exists, it does not resemble a mesentery from which the organism derived its name. This term, however, can still be applied to the European strains. Since the American strains are identical with *Bacillus pumilus* (Chester, Del. Agr. Exp. Station, 15th Ann. Report, 1903, 87; Lawrence and Ford, Jour. Bact., *1*, 1916, 300), it has been recommended (Smith, Gordon, and Clark, *loc. cit.*) that they be designated as *Bacillus pumilus* to avoid ambiguity. Since the European *Bacillus mesentericus* is only a stage of growth of *Bacillus subtilis*, the former name should be dropped.

Bakt., II Abt., *19*, 1907, 117); *Bacillus truffauti* Truffaut and Bezssonoff, Compt. rend. Acad. Sci., Paris, *175*, 1922, 544; *Bacillus mesentericus hydrolyticus* Hermann and Neuschul, Biochem. Ztschr., *281*, 1935, 219.

The name *Vibrio subtilis* Ehrenberg (Infusionsthierchen als vollkommene Organismen, Leipzig, 1838) seems to have given rise to the species name.

Spores: 0.6 to 0.9 by 1.0 to 1.5 microns, ellipsoidal to cylindrical, central or paracentral. Germination prevailingly equatorial.

Sporangia: Ovoid to cylindrical, only slightly bulged if at all.

Rods: 0.7 to 0.8 by 2.0 to 3.0 microns, single or in short chains, rounded ends, stain uniformly. Motile. Gram-positive. The following variations have been observed: Smaller or larger rods, filaments, encapsulated cells (the slimy bread organisms), few shadow forms, non-motile and Gram-variable. Rods on glucose nutrient agar store small amount of fat.

Gelatin stab: Liquefaction.

Agar colonies: Usually rough, finely wrinkled, opaque, dull, adherent, slightly spreading, brownish tinge. Variations may be smooth, soft, thin, translucent, non-adherent, dendroid, coarsely wrinkled, creamy-white to yellowish to orange.

Agar slants: Growth abundant, flat, spreading, usually has a dull mat surface, finely wrinkled, adherent, becoming slightly brownish. Variations may be coarsely wrinkled or folded, non-adherent, smooth, thin, translucent, dendroid, creamy-white to yellow to orange. Some strains show a greenish fluorescence when grown at 45°C on nutrient agar.

Broth: Turbid becoming clear with formation of a tough, wrinkled pellicle.

Milk: Slowly peptonized, becoming alkaline.

** There has been confusion about the identity of the so-called slimy bread bacteria. Lehmann and Neumann (Bakt. Diag., 7 Aufl., *2*, 1927, 616) stated that they were interrelated and also more or less closely related to *Bacillus mesentericus* and to *Bacillus vulgatus*. Laubach (Jour. Bact., *1*, 1916, 501) isolated a strain of *Bacillus panis* that lost its capsules on artificial media, although it still remained slimy. From this and the work of Smith, Gordon and Clark (*loc. cit.*) it is apparent that the slimy bread organisms are mucoid variants of *Bacillus subtilis*, which may or may not be encapsulated, and motile or non-motile (see also *Bacillus subtilis* var. *viscosus* Chester, Del. Agr. Exp. Station, 15th Ann. Report, 1903, 84).

Milk agar plate: Casein hydrolyzed.

Potato: Growth luxuriant, warty or wrinkled to coarsely folded, whitish to pink or yellow, becoming brownish with age.

Nitrites formed from nitrates.

Starch is hydrolyzed.

Acid with ammoniacal nitrogen from xylose, arabinose, glucose, fructose, galactose, mannose, maltose, sucrose, salicin, glycerol, and mannitol. Usually acid from dextrin. Variable reactions on rhamnose, raffinose, and inulin. Usually no action on lactose.

Acetylmethycarbinol produced.

Citrates utilized.

Optimum temperature 30° to 37°C. Will usually grow from 50° to 56°C.

Aerobic, facultative.

Source: Original cultures isolated by Cohn from an infusion of lentils (1872), from a boiled infusion of cheese and white beets (1875), and from boiled hay infusions (1876). Hence, frequently called the hay bacillus. The folded, non-adherent stage of growth (*Bacillus vulgatus* and the European strain of *Bacillus mesentericus*) is often called the potato bacillus. Manner of germination of spores established by Prazmowski (*loc. cit.*).

Habitat: Widely distributed in soil and in decomposing organic matter.

Note: *Bacillus vulgatus* has long been separated from *Bacillus subtilis* by the folded character and the non-adherence of its growth. Recently Lamanna (Jour. Bact., *44*, 1942, 611) has attempted to separate this species from *Bacillus subtilis* by the splitting of the spore sheath along the transverse axis upon germination. Since the two species are otherwise morphologically and physiologically alike and since these characters are subject to much variation, there seems to be no valid reason for this separation. One can, if he desires, indicate the different stages of growth; for instance, *Bacillus subtilis* morphotype *vulgatus* (or *mesentericus*) for the folded growth, *Bacillus subtilus* morphotype *panis* for the slimy growth, and *Bacillus subtilis* morphotype *globigii* for those that produce a red or orange pigment. These terms would apply to the present condition of the culture and would have to be changed if the character of the growth changed.

1a. *Bacillus subtilis* var. *aterrimus* *comb. nov.* (Potato bacillus, Biel, Cent. f. Bakt., II Abt., *2*, 1896, 137; *Bacillus aterrimus* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 303; *Bacillus mesentericus niger* Lunt, Cent. f. Bakt., II Abt., *2*, 1896, 572; *Bacillus niger* Chester, Man. Determ. Bact., 1901, 306.) From Latin *aterrimus*, very black.

Synonyms: *Bacillus nigrificans* Fabian and Nienhuis, Mich. Agric. Exp. Station, Tech. Bull. 140, 1934, 24; *Bacillus tyrosinogenes* Rusconi, as referred to by Carbone et al., Instit. Sierot. Milan., *2*, 1921–1922, 29; not *Bacillus tyrosinogenes* Hall and Finnerud, Proc. Soc. Expl. Biol. and Med., *19*, 1921, 48 and Hall, Abstr. Bact., *6*, 1922, 6.

In the early accounts the production of a blue-black to black pigment on potato was stressed. It was also said to resemble *Bacillus subtilis* and *Bacillus vulgatus* on gelatin plates. Recent work (Clark and Smith, Jour. Bact., *37*, 1939, 280) has shown that pigmentation occurs only in the presence of a carbohydrate. In addition (Gordon and Smith, Jour Bact., *43*, 1942, 55), it was established that the ability to form the pigment could be lost through serial transfers and colony selection and that the resultant dissociants could not be differentiated from *Bacillus subtilis*.

Source: Isolated from rye bread in moist chamber used for growing some aspergilli (Biel).

Habitat: Widely distributed in soil.

1b. *Bacillus subtilis* var. *niger* *comb. nov.* (*Bacillus lactis niger* Gorini, Gior. d. Reale Soc. Ital. Ig., *16*, 1894, 9; *Bacil-*

lus niger Migula, Syst. der Bakt., *2*, 1900, 636.) From Latin *niger*, black.

The black pigment characterizing this organism is formed only in media containing tyrosine (Clark and Smith, Jour. Bact., *37*, 1939, 279). The ability to form the pigment may be lost through serial transfer and colony selection. It then cannot be separated from *Bacillus subtilis* (Gordon and Smith, *loc. cit.*).

Source: First isolated from milk.

Habitat: Widely distributed in soil.

2. **Bacillus pumilus** Gottheil. (Cent. f. Bakt., II Abt., 7, 1901, 681.) From Latin *pumilus*, dwarfish, little.

Synonyms: *Bacillus mesentericus* as interpreted by Chester, Del. Agric. Exp. Station, 15th Ann. Report, 1903, 87; *Bacillus mesentericus* as given by Lawrence and Ford, Jour. Bact., *1*, 1916, 295 and 300; *Bacillus mesentericus* var. *flavus* Laubach, Jour. Bact., *1*, 1916, 497; perhaps also *Bacillus parvus* Neide, Cent. f. Bakt., II Abt., *12*, 1904, 344; *Bacillus leptodermis* Burchard, Arb. a. d. bakt. Inst. d. techn. Hochschule zu Karlsruhe, *2*, 1898, 33.

Spores: Ellipsoidal to cylindrical, thin walled, naked, central or paracentral, usually about 0.5 by 1.0 micron although some may approach the size of those of *Bacillus subtilis*.

Sporangia: Ellipsoidal to cylindrical, not bulged.

Rods: 0.6 to 0.7 by 2.0 to 3.0 microns, usually occurring singly or in pairs. Chains, filaments and shadow forms may be found in some strains. Cells grown on glucose nutrient agar have few small fat globules. Motile with peritrichous flagella. Gram-positive.

Gelatin stab: Slow liquefaction.

Agar colonies: Thin, flat, spreading, dendroid, smooth, translucent. The rough stage also occurs.

Agar slants: Growth moderate, smooth, soft, thin, glistening, non-adherent, spreading, usually whitish although it may be yellowish. The rough stage is tough and finely wrinkled, sometimes resembling certain strains of *Bacillus subtilis*.

Broth: Uniform turbidity, with or without a ring or half-formed pellicle. The rough stage forms a pellicle.

Milk: Peptonized, sometimes coagulated.

Milk agar plate: Casein hydrolyzed.

Potato: Growth is smooth, thin, spreading, moist to slimy, yellowish, turning somewhat brown. The rough stage is dry and finely wrinkled.

Nitrites not produced from nitrates.

Starch not hydrolyzed.

Acid with ammoniacal nitrogen from arabinose, xylose, glucose, fructose, galactose, mannose, sucrose, salicin, glycerol and mannitol; usually also from maltose and raffinose. Reaction variable with dextrin. Usually no acid from rhamnose, lactose, and inulin.

Acetylmethylcarbinol produced.

Citrates utilized as sole source of carbon.

Optimum temperature about 30°C. Maximum temperature allowing growth usually about 50°C.

Aerobic.

Source: Isolated from plants, cheese, dust, and as a contaminant of media.

Habitat: Widely distributed in nature.

3. **Bacillus coagulans** Hammer. (Iowa Agric. Exp. Station, Research Bull. 19, 1915, 129; Sarles and Hammer, Jour. Bact., *23*, 1932, 301.) From Latin *coagulans*, curdling, coagulating.

Synonyms: *Bacillus thermoacidurans* Berry, Jour. Bact., *25*, 1933, 72; *Bacillus dextrolacticus* Andersen and Werkman, Iowa State Coll. Jour. of Sci., *14*, 1940, 187.

Spores: Ellipsoidal to cylindrical, terminal or subterminal, thin walled, 0.6 to 0.9 by 1.0 to 1.5 microns. Sporulation better on acid proteose peptone agar (Stern, Hegarty, and Williams, Food Research, 7, 1942, 186).

Sporangia: Only slightly swollen, if at all.

Rods: 0.5 to 0.9 by 2.5 to 3 microns, singly or in short chains, resemble *Bacillus subtilis*. Cells from glucose agar contain few small fat globules. Motile. Gram-positive.

Gelatin: No growth at 20°C. No change in gelatin by Frazier method at 45°C.

Agar colonies: Small, entire, raised, not characteristic.

Agar slants: Growth scant to moderate, thin, flat. On acid proteose peptone agar growth is more abundant and microscopically the cells appear healthier.

Broth: Moderate uniform turbidity, followed by clearing. Glucose broth attains a pH of 4.0 to 4.4.

Milk: Coagulated.

Milk agar plate: Weak hydrolysis of casein.

Potato: Growth scant to moderate, thin, spreading, white to cream-colored. May have a sour odor.

Nitrites usually not formed from nitrates.

Starch is hydrolyzed.

Acid from glucose, galactose, fructose, lactose, maltose, sucrose, dextrin, and glycerol. Usually no acid from arabinose and sorbitol. No acid from xylose and mannitol. Organic nitrogen preferable to inorganic.

Acetylmethylcarbinol produced.

Citrates not used as sole source of carbon.

Optimum temperature about 45°C (Hammer, 55°C). Maximum temperature allowing growth 54°C to 60°C. Slow growth, if any, at 25°C.

Aerobic, facultative.

Source: Isolated from evaporated milk (Hammer) and tomato juice (Berry).

Habitat: Canned goods; probably widely distributed in nature.

4. **Bacillus firmus** Werner. (Cent. f. Bakt., II Abt., *87*, 1932, 470.) From Latin *firmus*, firm, strong.

Spores: Usually ellipsoidal, central to subterminal, 0.6 to 0.7 by 1.0 to 1.2 microns on Ca-n-butyrate agar (Werner); 0.7 to 0.9 by 1.0 to 1.4 microns on nutrient agar. Sporulation better on plain peptone agar than on nutrient agar.

Sporangia: Ellipsoidal to cylindrical, sometimes slightly bulged.

Rods: 0.6 to 0.9 by 1.5 to 4.0 microns, single or in short chains, few filaments. On glucose nutrient agar there are swollen, shadow, and other abnormal forms, few small fat globules. Motile with peritrichous flagella. Gram-positive.

Gelatin stab: Slow liquefaction. Gelatin plate shows wide zone of hydrolysis.

Agar colonies: Small, smooth, dense, entire, white to pink.

Agar slants: Growth moderate, smooth, opaque, not spreading, whitish. Pink variations may occur. Growth inhibited when glucose is added, because of the production of acid. No growth at pH 6.0 or below.

Broth: Scant uniform turbidity or a flocculent growth.

Milk agar plate: Weak to strong casein hydrolysis.

Potato: No growth.

Nitrites produced from nitrates.

Starch is hydrolyzed.

Acid from glucose. No acid from arabinose and xylose. Ammonium salts not used as sole source of nitrogen.

Acetylmethylcarbinol not produced.

Citrates usually not utilized.

Urease not produced.

Salt tolerance: Will grow in nutrient broth containing 4 to 7 per cent NaCl.

Optimum temperature about 28°C. Maximum temperature allowing growth 37°C to 45°C.

Source: Seven strains isolated from soils in Central Europe and Egypt.

Habitat: Widely distributed in soil.

5. **Bacillus lentus** Gibson. (Cent. f. Bakt., II Abt., *92*, 1935, 368.) From Latin *lentus*, slow.

Spores: Ellipsoidal, central to subterminal, 0.7 to 0.8 by 1.0 to 1.3 microns.

Sporangia: Ellipsoidal to cylindrical, may be slightly swollen.

Rods: 0.6 to 0.7 by 2.0 to 3.0 microns, occurring singly or in pairs. Motile with peritrichous flagella. Gram-positive.

Gelatin stab: No liquefaction. No change in gelatin by Frazier method.

Agar colonies: Small, smooth, entire, glistening, white, opaque.

Agar slants: Growth only moderate, slow, thin, gray to white, opaque, not spreading. No growth at pH 6.0 or below. Growth inhibited by glucose because of the change to acid reaction.

Broth: Faint uniform turbidity, granular sediment.

Milk: Unchanged.

Milk agar plate: Casein not hydrolyzed.

Potato: No growth.

Nitrites not produced from nitrates.

Starch is hydrolyzed.

Acid from arabinose, xylose, glucose, sucrose, and lactose. Inorganic nitrogen not utilized.

Acetylmethylcarbinol not formed.

Citrates not used as sole source of carbon.

Urease produced. Urea decomposed at room temperature, feebly at 37°C.

Salt tolerance: Will grow in nutrient broth containing 4 per cent NaCl.

Optimum temperature about 25°C. Maximum temperature allowing growth 37°C.

Growth on most media is increased by the addition of urea.

Aerobic.

Source: Nine strains isolated from soils.

Habitat: Common in soils.

6. **Bacillus megatherium** De Bary. (*Bacillus megaterium* (sic) De Bary, Vergleichende Morph. und Biol. der Pilze, 1884, 499.) Generally assumed that the original spelling was a typographical error and that the later spelling *megatherium* comes from Greek roots meaning big animal (Breed, Science, *70*, 1929, 480). Rippel (Arch. Mikrobiol., *11*, 1940, 470) holds that the original spelling meaning big rod is the correct form.

Synonyms as given by Smith, Gordon, and Clark (*loc. cit.*): *Bacillus capri* Stapp, Cent. f. Bakt., II Abt., *51*, 1920, 19; *Bacillus carotarum* Koch, Bot. Zeit., *18*, 1888, 277 (*Bacterium carotarum* Migula, Syst. d. Bakt., *2*, 1900, 293); *Bacillus cobayae* Stapp, Cent. f. Bakt., II Abt., *51*, 1920, 10; *Bacillus danicus* Löhnis and Westermann, Cent. f. Bakt., II Abt., *22*, 1908, 253; *Bacillus graveolens* Gottheil, Cent. f. Bakt., II Abt., *7*, 1901, 496 and 535; *Bacillus malabarensis* Löhnis and Pillai, Cent. f. Bakt., II Abt., *19*, 1907, 91; *Bacillus musculi* Stapp, Cent. f. Bakt., II Abt., *51*, 1920, 39; *Bacillus oxalaticus* Migula, Arb. a. d. bakt. Inst. d. Tech. Hochschule z. Karlsruhe, *1*, Heft, 1, 1894, 139; *Bacillus petasites* Gottheil, Cent. f. Bakt., II Abt., *7*, 1901, 535 (Lawrence and Ford, Jour. Bact., *1*, 1916, 273); *Bacillus ruminatus* Gottheil, *ibid.*, 496; *Bacillus silvaticus* Neide, Cent. f. Bakt., II Abt., *12*, 1904, 32; *Bacillus tumescens* Zopf, Die Spaltpilze, 1 Aufl., 1883, 66 (*Zopfiella tumescens* Trevisan, Car. d. alc. nuov. gen. di Batter., 1885, 4).

Other possible synonyms given by Neide (*loc. cit.*, 11): *Bacterium hirtum* Henrici, Arb. bakt. Inst. Karlsruhe, *1*, 1894, 44 (*Pseudomonas hirtum* Ellis, Cent. f. Bakt., II Abt., *11*, 1903, 243; *Bacillus hirtus* Ellis, Ann. Bot., *20*, 1906, 233); *Bacillus brassicae* Pommer, Mitt. botan. Inst. Graz, *1*, 1886, 95 (*Bacterium brassicae* Migula, Syst. d. Bakt., *2*, 1900, 296).

Although the name *Bacillus tumescens* Zopf (which is here regarded as a probable synonym) has priority over *Bacillus megatherium*, the latter name is preferred because of general usage. Neither of the original descriptions is sufficiently detailed to characterize adequately the

species named, and Zopf (Die Spaltpilze, 3 Aufl., 1885, 82–83) regarded the two species as distinct. The modern work on which the present description of *Bacillus megatherium* is based has been largely carried out with cultures identified as *Bacillus megatherium*, and the true nature of the species is really fixed by the informal emendations made in these more recent descriptions. The emended descriptions give this name a more certain meaning than is given *Bacillus tumescens* by the descriptions existent in the literature.

Spores: Ellipsoidal, sometimes nearly round, central to paracentral, 1.0 to 1.5 by 1.5 to 2.0 microns (larger dimensions have been reported).

Sporangia: Ellipsoidal to cylindrical, often in short chains; not swollen.

Rods: 1.2 to 1.5 by 2.0 to 4.0 microns, occurring singly and in short chains. Larger and smaller cells, irregular, twisted, and shadow forms are present in some strains, depending upon the substrate. Cells from glucose or glycerol nutrient agar usually store much fat and stain unevenly (vacuolated) with dilute stains. Motility with peritrichous flagella, usually slow, although some strains may show active motility. Gram-positive.

Gelatin stab: Slow liquefaction.

Agar colonies: Large, smooth, soft, convex, entire, opaque, creamy-white to yellow. The rough stage is usually concentrically ridged with a thin edge.

Agar slants: Growth abundant, soft, butyrous, creamy-white to yellow with pellucid dots. Browning with age; a few strains become black if the medium contains tyrosine.

Broth: Medium to heavy uniform turbidity.

Milk: Peptonized.

Milk agar plate: Casein hydrolyzed.

Potato: Growth abundant, smooth, soft to slimy, spreading, creamy-white, pale to lemon-yellow or pink. A few strains are orange-colored, some blacken the potato. The rough stage is wrinkled.

Nitrites usually not produced from nitrates.

Starch is hydrolyzed.

Acid with ammoniacal nitrogen from arabinose, glucose, fructose, sucrose, maltose, dextrin, inulin, salicin, glycerol and mannitol. Usually acid from xylose, galactose, mannose, and raffinose; variable from lactose. Generally no acid from rhamnose.

Acetylmethylcarbinol not formed.

Citrates used as sole source of carbon.

Uric acid hydrolysis: Variable.

Optimum temperature 28°C to 35°C. Maximum temperature allowing growth usually between 40°C and 45°C.

Source: Originally isolated from cooked cabbage.

Habitat: Widely distributed in soil, water, and decomposing materials.

NOTE: A description of *Bacillus megatherium—Bacillus cereus* intermediates follows the description of *Bacillus cereus*.

7. **Bacillus cereus** Frankland and Frankland. (Philosoph. Transact. Roy. Soc. London, *178*, B, 1887, 279.) From Latin *cereus*, waxy.

Synonyms: *Bacillus ellenbachensis alpha* Stutzer and Hartleb, Cent. f. Bakt., II Abt., *4*, 1898, 31; *Bacillus ellenbachensis* Gottheil, Cent. f. Bakt., II Abt., *7*, 1901, 540; *Bacterium petroselini* Burchard, Arb. bakt. Inst. Karlsruhe, *2*, 1898, 39 (*Bacillus petroselini* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 414).

The following are given as possible synonyms by Gottheil, Cent. f. Bakt., II Abt., 7, 1901, 540: *Bacillus ramosus liquefaciens* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 342; *Bacillus stoloniferus* Pohl, Cent. f. Bakt., *11*, 1892, 142 (*Bacterium stoloniferus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 91; *Achromobacter stoloniferum* Bergey et al., Manual, 1st ed., 1923, 136); *Bacillus limosus* Russell, Ztschr. f. Hyg., *11*,

1892, 196 (not *Bacillus limosus* Klein, Ber. d. deutsch. bot. Gesellsch., *7*, 1889, 65; *Bacillus limophilus* Migula, Syst. d. Bakt., *2*, 1900, 550); *Bacillus brevis o* Flügge, Ztschr. f. Hyg., *17*, 1894, 294; *Bacillus lutulentus* Kern, Arb. bakt. Inst. Karlsruhe, *1*, 1897, 402; *Bacillus goniosporus* Burchard, Arb. bakt. Inst. Karlsruhe, *2*, 1898, 14; *Bacterium turgescens* Burchard, *ibid.*, 18; *Bacillus cursor* Burchard, *ibid.*, 25; *Bacillus loxosus* Burchard, *ibid.*, 37.

The following are also listed as synonyms or biotypes of *Bacillus cereus* by Smith, Gordon and Clark: *Bacillus sessilis* Klein, Cent. f. Bakt., *6*, 1889, 349 and 377 (*Bacterium sessile* Migula, Syst. d. Bakt., *2*, 1900, 290); *Bacillus albolactis* Migula, *ibid.*, 577 (*Bacillus lactis albus* Loeffler, Berlin. klin. Wchnschr., 1887, 630); *Bacillus lacticola* Neide, Cent. f. Bakt., II Abt., *12*, 1904, 168 (Bacillus No. V, Flügge, Ztschr. f. Hyg., *17*, 1894, 294; *Bacillus lactis* No. V, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 208; *Bacterium lacticola* Migula, Syst. d. Bakt., *2*, 1900, 305; *Bacillus excurrens* Migula, *ibid.*, 582; *Bacillus cereus* Chester, Man. Determ. Bact., 1901, 278; not *Bacillus cereus* Frankland and Frankland, Philos. Trans. Roy. Soc. London, *178*, B, 1887, 279); *Bacillus lactis* Neide, Cent. f. Bakt., II Abt., *12*, 1904, 337 (*Bacillus No. I*, Flügge, Ztschr. f. Hyg., *17*, 1894, 294; *Bacillus flüggei* Chester, Manual Determ. Bact., 1901, 281); *Bacillus robur* Neide, Cent. f. Bakt., II Abt., *12*, 1904, 18; *Bacillus thuringiensis* Berliner, Zeit. f. angew. Entomol., *2*, 1915, 29 (see also Mattes, Gesellschaft zur Beförd. der Gesam. Naturw., *62*, 1927, 381; *Bacterium thuringiensis* Chorine, Internat. Corn Borer Invest., *2*, 1929, 50); *Bacillus cereus* var. *fluorescens* Laubach, Jour. Bact., *1*, 1916, 508 (*Bacillus fluorescens* Bergey et al., Manual, 1st ed., 1923, 298; not *Bacillus fluorescens* Trevisan, I generi e le specie delle Batteriacee, 1889, 18); *Bacillus subtilis* Michigan strain, Conn., Jour. Inf. Dis., *46*, 1930, 341; *Bacillus undulatus* den Dooren de Jong, Cent. f. Bakt., I Abt., Orig., *122*, 1931, 277 (see also den Dooren de Jong, Arch. f. Mikrobiol., *4*, 1933, 36); *Bacillus siamensis* Siribaed, Jour. Inf. Dis., *57*, 1935, 143 (see also *Bacillus cereus* var. *siamensis* Clark, Jour. Bact., *33*, 1937, 435); *Bacillus metiens* Charlton and Levine, Iowa Eng. Exp. Station, Bull. 132, 1937, 18; (see also Levine, Buchanan and Lease, Iowa State Coll. Jour. Sci., *1*, 1927, 379); *Bacillus tropicus* Heaslip, Med. Jour. Australia, *28*, 1941, 536.

Neide (*loc. cit.*) gave the following as possible synonyms of *Bacillus lacticola: Bacillus butyricus* Hueppe, Mitteil. a. d. kaiserl. Gesundheitsamte, *2*, 1884, 309; not *Bacillus butyricus* Macé, Traité de Bact., 1st ed., 1888 (*Clostridium butyricum* Prazmowski, Untersuchungen über die Entwickelungsgeschichte und Fermentwirkung einiger Bacterien-Arten. Inaug. Diss., Leipzig, 1880, 23); *Bacillus aureus* Pansini, Arch. f. pathol. Anat. u. Physiol., *122*, 1890, 436 (not *Bacillus aureus* Frankland and Frankland, Philos. Trans. Roy. Soc. London, *178*, B, 1887, 272); *Bacillus lacteus* Migula, Syst. d. Bakt., *2*, 1900, 571 (No. 17, Lembke, Arch. f. Hyg., *29*, 1897, 323); *Bacillus goniosporus* Burchard, *loc. cit.*

Neide also gave the following as possible synonyms of *Bacillus lactis: Bacillus lutulentus* Kern, *loc. cit.*; *Bacillus agglomeratus* Migula, Syst. der Bakt., *2*, 1900, 557; *Bacillus amarificans* Migula, *ibid.*, 584; *Bacillus cylindrosporus* Burchard, Arb. bakt. Inst. Karlsruhe, *2* 1898, 31.

Other possible synonyms of *Bacillus cereus* are: *Bacillus anthracoides* Hüppe and Wood, Ber. klin. Wchnschr., *16*, 1889, 347 (Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 232; *Bacterium anthracoides* Migula, Syst. der Bakt., *2*, 1900, 281; not *Bacterium anthracoides* Trevisan, I generi e le specie delle Batteriacee, 1889, 20); *Bacillus pseudanthracis* Wahrlich, Bakteriol. Studien, Petersburg, 1890–91, 26 (not

Bacillus pseudanthracis Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 233; *Bacterium pseudoanthracis* Migula, *loc. cit.*, 282); *Bacterium flexile* Burchard, Inaug. Diss., Karlsruhe, 1897 and Arb. bakt. Inst. Karlsruhe, *2*, 1898, 16; *Bacillus ellenbachi* Sawamura, Tokyo Imp. Univ. Coll. Agr. Bull. *7*, 1906, 105; *Bacillus hoplosternus* Paillot, Compt. rend. Acad. Sci., Paris, *163*, 1916, 772; *Bacillus fulminans* Schrire and Greenfield, Trans. Roy. Soc. So. Africa, *17*, 1929, 309.

Spores: Ellipsoidal, average size 1.0 by 1.5 microns (considerable variation has been noted by various writers), central or paracentral, usually freely formed in 24 hours. Germination prevailingly polar.

Sporangia: Ellipsoidal or cylindrical, only slightly swollen, if at all. In short to long chains.

Rods: 1.0 to 1.2 by 3.0 to 5.0 microns, occurring in long chains, ends square. Cells appear granular or foamy if lightly stained, especially if grown on glucose or glycerol nutrient agar; fat usually stored. Smooth strains are motile with many peritrichous flagella, rough strains weakly motile or non-motile. Gram-positive.

Gelatin stab: Rapid liquefaction.

Agar colonies: Large, flat, entire or irregular, whitish with characteristic appearance by transmitted light described by various observers as ground glass, moire silk, or galvanized iron. All stages occur from the thin, spreading, very rough and arborescent, to the smooth dense form of colony.

Agar slant: Growth abundant, usually non-adherent, spreading, dense, whitish to slightly yellowish. Old slants show characteristic whip-like outgrowths. Some strains produce a yellowish-green fluorescence.

Broth: Heavy uniform turbidity, with or without a fragile pellicle.

Milk: Rapid peptonization, with or without slight coagulation.

Blood serum: Partially liquefied. Hemolysis on blood agar.

Potato: Growth abundant, thick, soft, creamy-white to pinkish, spreading over the potato. Rough strains may be folded and more pigmented.

Nitrites usually produced from nitrates.

Starch is hydrolyzed.

Acid (with ammoniacal nitrogen) from glucose, fructose, maltose, dextrin, and glycerol. Acid usually from sucrose and salicin. Usually no acid from mannose and lactose. No acid from arabinose, rhamnose, xylose, raffinose, inulin, and mannitol.

Acetylmethylcarbinol produced.

Citrates usually utilized as sole source of carbon.

Optimum temperature about 30°C. Maximum temperature allowing growth varies from 37°C to 48°C, usually about 43°C.

Aerobic.

Source: From soil, dust, milk, plants, and as contaminant of media.

Habitat: Widely distributed. Occurs more often in soil than any other member of the genus. See Chester, Del. Agr. Exp. Station, 15th Ann. Report, 1903, 73; Lawrence and Ford, Jour. Bact., *1*, 1916, 284; Conn, N. Y. Exp. Station, Tech. Bull. 58, 1917; Conn and Breed, Jour. Bact., *4*, 1919, 273; Soriano, Thesis, Univ. Buenos Aires, 1935, 569.

Bacillus megatherium—Bacillus cereus intermediates.

According to Smith, Gordon, and Clark (*loc. cit.*) intermediate forms occur between *Bacillus megatherium* and *Bacillus cereus* which cannot be represented by a distinct species. These intermediates are characterized morphologically by the early appearance on agar of shadow or distorted forms, long filaments, and generally only a few spores. Fat globules are smaller and less numerous. Physiologically the group is erratic, showing a progression of characters from *Bacillus megatherium* on the one hand to *Bacillus cereus* on the other. Acetylmethylcarbi-

nol and nitrites are not usually formed. Fermentation of the pentoses and mannitol, the ability to grow well on glucose nitrate agar, susceptibility to the bacteriophage active against *Bacillus megatherium* or *Bacillus cereus* and the general character of the growth determines whether the intermediate is more closely related to *Bacillus megatherium* or to *Bacillus cereus*.

Bacillus cohaerens Gottheil (Cent. f. Bakt., II Abt., *7*, 1901, 458 and 689) may be taken as a representative of this intermediate group resembling *Bacillus megatherium* more closely than *Bacillus cereus*. Gottheil gave as possible synonyms: *Bacillus vermicularis* Frankland and Frankland, Ztschr. f. Hyg., *6*, 1889, 384 (*Bacterium vermiculare* Migula, Syst. d. Bakt., *2*, 1900, 302); *Bacillus filiformis* Tils, Ztschr. f. Hyg., *9*, 1890, 293; *Bacillus lactis albus* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 110; *Bacillus virgatus* Kern, Arb. bakt. Inst. Karlsruhe, *1*, 1897, 416; *Bacillus cylindrosporus* Burchard, Arb. bakt. Inst. Karlsruhe, *2*, 1898, 31; *Bacillus bipolaris* Burchard, *ibid.*, 34.

Other strains which apparently belong to this same group are: *Bacterium pansinii* Migula, Syst. d. Bakt., *2*, 1900, 303 (Bacillus No. 3, Pansini, Arch. f. path. Anat., *122*, 1890, 439; *Bacterium granulatum* Chester, Man. Determ. Bact., 1901, 189); *Bacterium tomentosum* Henrici, Arb. bakt. Inst. Karlsruhe, *1*, 1897, 40; *Bacillus teres* Neide, Cent. f. Bakt., II Abt., *12*, 1904, 161.

Representing those strains in this intermediate group more closely related to *Bacillus cereus* is *Bacillus simplex* Gottheil (*loc. cit.*, 685). Gottheil gave the following as possible synonyms: *Bacillus vacuolosis* Sternberg, Manual of Bact., 1893, 717; *Bacillus natans* Kern, Arb. bakt. Inst. Karlsruhe, *1*, 1897, 413; *Bacillus loxosporus* Burchard, Arb. bakt. Inst. Karlsruhe, *2*, 1898, 49.

7a. *Bacillus cereus* var. *mycoides* (Flügge) *comb. nov.* (*Bacillus mycoides* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 324.) From Greek *mykes*, fungus; *eidos*, form, shape, i.e., fungus-like.

Gottheil, Cent. f. Bakt., II Abt., *7*, 1901, 589, gave the following as probable synonyms: Wurzelbacillus, Eisenberg, Bakt. Diag., 1st ed., 1886, 4; *Bacillus figurans* Crookshank, Manual, 1st ed., 1886 (*Bacterium figurans* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 134); *Bacillus brassicae* Pommer, Mitt. a. d. botan. Inst. zu Graf, *1*, 1886, 95 (*Bacterium brassicae* Migula, Syst. d. Bakt., *2*, 1900, 296); *Bacterium casei* Migula, Syst. d. Bakt., *2*, 1900, 304 (Bacillus No. XVI, Adametz, Landw. Jahrb., *18*, 1889, 248; *Bacterium proteum* Chester, Man. Determ. Bact., 1901, 195); *Bacillus ramosus* Frankland and Frankland, Ztschr. f. Hyg., *6*, 1889, 388 (not *Bacillus ramosus* Veillon and Zuber, Arch. Méd. Exp. et Anat. Path., *10*, 1898, 542); *Bacillus radicosus* Zimmermann, Die Bakterien unserer Trink- u. Nutzwässer, etc., I Reihe, 1890, 30 (*Bacterium radicosum* Migula, Syst. d. Bakt., *2*, 1900, 283); *Bacillus implexus* Zimmermann, *ibid.* (*Bacterium implexum* Migula, *ibid.*, 298); *Bacillus intricatus* Migula, *ibid.*, 546 (*Cladothrix intricata* Russell, Ztschr. f. Hyg., *11*, 1892, 191).

Another possible synonym is *Bacillus praussnitzii* Trevisan (I generi e le specie delle Batteriacee, 1889, 20). Laubach, Jour. Bact., *1*, 1916, 495, found that this differed from *Bacillus mycoides* only in the fermentation of lactose. This has been substantiated by later work.

Holzmüller (Cent. f. Bakt., II Abt., *23*, 1909, 304) described four varieties of *Bacillus mycoides* which he designated by Greek letters and in addition named four new species which were apparently only variations of *Bacillus mycoides*: *Bacillus effusus*, *Bacillus olfactorius*, *Bacillus nanus* and *Bacillus dendroides* (not *Bacillus dendroides* Thornton, Ann. Appl. Biol., *9*, 1922, 247).

Bacillus cereus var. *mycoides* is identi-

cal in all respects with *Bacillus cereus* except in the following characters:

Agar colonies: Grayish, thin, widely spreading by means of long twisted chains of cells, turning to the right or left.

Agar slants: Growth thin, rhizoid, grayish, widely spreading, adhering to or growing into the agar. Later, growth becomes thicker and softer.

The physiological similarity between *Bacillus cereus* and *Bacillus mycoides* has often been noted. Gordon (Jour. Bact., *39*, 1940, 98) showed that the rhizoid character of the growth of *Bacillus mycoides* was readily lost by cultivation in flasks containing 100 ml of broth and that the resulting dissociants could not be differentiated from *Bacillus cereus*. It is, therefore, a question whether *Bacillus mycoides* should be given the dignity of a variety of *Bacillus cereus* or merely designated as a stage of growth (morphotype).

Source: Isolated from soil.

Habitat: Widely distributed in soil.

8. **Bacillus anthracis** Cohn *emend.* Koch. (Les infusories de la maladie charbonneuse, Davaine, Compt. rend. Acad. Sci., Paris, *69*, 1864, 393; Cohn, Beiträge z. Biol. d. Pflanzen, *1*, Heft 2, 1872, 177; Koch, *ibid.*, *2*, Heft 2, 1876, 279; Bactéridie des charbon, Pasteur and Joubert, Compt. rend. Acad. Sci., Paris, *84*, 1877, 900; *Bacterium anthracis* Zopf, Die Spaltpilze, 2 Aufl., 1884, 45; *Bacillus (Streptobacter) anthracis* Schroeter, Kryptogamen Flora v. Schlesien, *3*, 1, 1886, 163; *Pollendera anthracis* Trevisan, 1884, see Trevisan, I generi e le specie delle Batteriacee, 1889, 13; *Bacterium anthracis* Migula, in Engler and Prantl, Die natürlichen Pflanzenfam., *1*, 1a, 1895, 21; *Aplanobacter anthracis* Erw. Smith, Bacteria in Relation to Plant Diseases, 1905, 171; *Bacillus (Bacteridium) anthracis* Buchanan, Jour. Bact., *3*, 1918, 37.) From Greek, gen. of *anthrax*, charcoal, a carbuncle, the disease anthrax.

According to Smith, Gordon, and Clark (*loc. cit.*) this species is a pathogenic variety of *Bacillus cereus*. They worked extensively with the latter but not with many strains of *Bacillus anthracis*. The only difference between the two seemed to be pathogenicity and motility, and some strains of *Bacillus cereus* are weakly pathogenic and some practically non-motile. It would appear that *Bacillus cereus* is a so-called *parent species* from which two varieties (var. *anthracis* and var. *mycoides*) and several morpho- and biotypes have sprung.

Spores: Ellipsoidal, 0.8 to 1.0 by 1.3 to 1.5 microns, central or paracentral, often in chains. Germination polar.

Sporangia: Ellipsoidal to cylindrical, not swollen, in chains.

Rods: 1.0 to 1.3 by 3 to 10 microns with square or concave ends, occurring in long chains, resemble *Bacillus cereus*. Cells from glucose or glycerol nutrient agar appear granular (vacuolated) if stained lightly; many fat globules present. Non-motile. Gram-positive.

Gelatin stab: Arborescent in depth, inverted pine tree. Liquefaction crateriform becoming stratiform.

Agar colonies: Large, irregular, dense, curled structure composed of parallel chains, similar to certain strains of *Bacillus cereus*.

Agar slant: Growth abundant, grayish, dense, spreading, with fimbriate borders.

Broth: Little or no turbidity, thick pellicle.

Milk: Coagulated, slightly acid, peptonized.

Potato: Growth abundant, spreading, white to creamy.

Nitrites formed from nitrates.

Starch is hydrolyzed.

Acid from glucose, fructose, sucrose, maltose, trehalose, and dextrin. Some strains produce late and slight acidity in glycerol and salicin. No definite fermentation occurs in arabinose, rhamnose, mannose, galactose, lactose, raffinose, inulin, mannitol, dulcitol, sorbitol, inosi-

tol, and adonitol (Stein, Vet. Med., *38*, 1943).

Acetylmethylcarbinol produced.

Optimum temperature about 35°C. Maximum temperature allowing growth about 43°C.

Aerobic, facultative.

Pathogenic for man, cattle, swine, sheep, rabbits, guinea pigs, mice, etc.

Source: From blood of infected animals.

Habitat. The cause of anthrax in man, cattle, sheep and swine.

9. **Bacillus polymyxa** (Prazmowski) Migula. (*Clostridium polymyxa* Prazmowski, Inaug. Diss., Leipzig, 1880, 37; Migula, Syst. der Bakt., *2*, 1900, 638; *Granulobacter polymyxa* Beijerinck, K. Akad. Wetenschap., Amsterdam, Sec. 2, *1*, 1903, No. 10; *Granulobacter polymyxa* var. *mucosum* and var. *tenax* Beijerinck and Van Delden, Cent. f. Bakt., II Abt., *9*, 1902, 13; further description by Gruber, Cent. f. Bakt., II Abt., *14*, 1905, 353; *Aerobacillus polymyxa* Donkèr, *loc. cit.*, 138.) From Greek *poly*, many or much; *myxa*, slime or mucus.

This and the species immediately following (*Bacillus macerans*) are sometimes placed in the sub-genus *Aerobacillus* Donker *emend.* Kluyver and Van Neil (Donker, Inaug. Diss., Delft, 1926, 138; Kluyver and Van Neil, Cent. f. Bakt., II Abt., *94*, 1936, 402; not *Aerobacillus* Pribram, Jour. Bact., *18*, 1929, 374; not *Aerobacillus* Janke, Cent. f. Bakt., II Abt., *80*, 1930, 481).

For a study of this group and a review of the literature see Porter, McCleskey and Levine, Jour. Bact., *33*, 1937, 163. They give the following as synonyms of *Bacillus polymyxa: Bacillus asterosporus* Migula (*Astasia asterospora* Meyer, Flora, Erg. Bd., *84*, 1897, 185; Migula, Syst. der Bakt., *2*, 1900, 528; *Aerobacillus asterosporus* Donker, *loc. cit.*, 141); *Bacillus ovoaethylicus* Pribram (*Bacillus mycoides* var. *ovoaethylicus* Wagner, Ztschr. f. Untersuch. d. Nahrungs- u. Genussmittel, *31*, 1916, 234; Pribram, Klassifikation der Schizomyceten, Leipzig und Wien, 1933, 86); *Bacillus aerosporus* Greer, Jour. Inf. Dis., *42*, 1928, 508.

Gottheil (Cent. f. Bakt., II Abt., *7*, 1901, 727) regarded the following as synonyms: *Bacillus thalassophilus* Russell, Ztschr. f. Hyg., *11*, 1892, 190; *Bacillus subanaerobius* Migula, Syst. der Bakt., *2*, 1900, 600.

Bredemann (Cent. f. Bakt., II Abt., *23*, 1909, 45) admitted that the organisms, *Bacillus asterosporus alpha*, *Bacillus dilaboides*, and *Bacillus clostridioides*, named by Haselhoff and himself in an earlier article (Landwirtsch. Jahrb., *35*, 1906, 420, 426, 432) were merely variants of *Bacillus asterosporus*.

The following is usually considered a variety or strain of *Bacillus polymyxa* differing from the latter mainly in the production of a violet pigment on potato and agar in the presence of peptone: *Bacillus violarius acetonicus* Bréaudat, Ann. Inst. Pasteur, *20*, 1906, 874 (*Aerobacillus violarius* Donker, Inaug. Diss., Delft, 1926, 141).

Also a probable synonym of *Bacillus polymyxa* is *Bacillus amaracrylus* Voisenet (Bacille de l'amertume, Voisenet, Compt. rend. Acad. Sci., Paris, *153*, 1911, 363; Voisenet, Ann. Inst. Pasteur, *32*, 1918, 477; *Aerobacillus amaracrylus* Donker, *loc. cit.*, 141). The chief character in which it differs from *Bacillus polymyxa* is its ability to dehydrate glycerol with the formation of acrolein.

Also a probable variant of *Bacillus polymyxa* is *Bacillus pandora* Corbet (Jour. Bact., *19*, 1930, 321). The chief characters in which the latter differs from the former are the production of acid without gas from glucose and the lack of diastatic action.

Spores: Ellipsoidal, 1.0 to 1.5 by 1.5 to 2.5 microns, central to subterminal, wall usually thick and stainable. Freely formed.

Sporangia: Swollen, spindle-shaped (clostridia), sometimes clavate.

Rods: 0.6 to 1.0 by 2.5 to 6.0 microns,

occurring singly or in short chains. Cells contain small fat globules when grown on glucose nutrient agar. Motile with peritrichous flagella. Gram-variable.

Gelatin stab: Slow liquefaction. Hydrolysis of gelatin always positive by Frazier technic.

Agar colonies: Thin, inconspicuous, lobed, spreading over entire plate. Rough forms are round, whitish, and sometimes tough.

Agar slant: Growth scant to moderate, indistinct to whitish. On glucose agar, the growth is much heavier, raised, gummy, glistening; gas is formed.

Broth: Uniform to granular turbidity, flocculent to slimy sediment. Rough stage forms pellicle. Final pH of glucose broth cultures 5.2 to 6.8.

Milk: Not coagulated, gas usually formed.

Milk agar plate: Casein hydrolyzed.

Potato: Growth moderate to abundant, whitish to light tan, potato decomposed with formation of gas. Growth of rough stains is denser and heaped up.

Nitrites are produced from nitrates.

Starch is hydrolyzed. Crystalline dextrins are not produced.

Acid and gas (with ammoniacal nitrogen) from arabinose, xylose, glucose, fructose, galactose, mannose, maltose, sucrose, lactose, trehalose, cellobiose, raffinose, melezitose, dextrin, inulin, salicin, glycerol, and mannitol. Gum is also usually formed. Erythritol, adonitol, dulcitol and inositol not fermented. With organic nitrogen no acid or gas from rhamnose or sorbitol (Porter, McCleskey, and Levine, *loc. cit.*, also Tilden and Hudson, Jour. Bact., *43*, 1942, 530). This, however, could not be confirmed by Smith, Gordon, and Clark (*loc. cit.*) who found that acid and gas were produced from both carbohydrates.

Hemicellulose and pectin are attacked (Ankersmit, Cent. f. Bakt., I Abt., Orig., *40*, 1905, 100). In glucose broth, ethyl alcohol and butylene-glycol are produced also small amounts of acetone and butyl alcohol.

Acetylmethylcarbinol is produced.

Citrates usually not utilized as sole source of carbon.

Optimum temperature about 30°C. No growth at 42°C to 45°C; good growth at 20°C, slow at 13°C.

Not agglutinated by *Bacillus macerans* sera, results with homologous sera irregular (Porter, McCleskey, and Levine, *loc. cit.*).

Aerobic, facultative.

Source: First isolations were from grain, soil, and pasteurized milk.

Habitat: Widely distributed in water, soil, milk, feces, decaying vegetables, etc.

In addition see: Chester, Del. Agr. Exp. Station, 15th Ann. Report, 1903, 65; Wund, Cent. f. Bakt., I Abt., Orig., *42*, 1906, 193, 289, 385; Wahl, Cent. f. Bakt., II Abt., *16*, 1906, 489; Ritter, Cent. f. Bakt., II Abt., *20*, 1908, 21; Meyer, Cent. f. Bakt., I Abt., Orig., *49*, 1909, 305; Bredemann, Cent. f. Bakt., II Abt., *23*, 1909, 41; Virtanen and Kurstom, Biochem. Ztschr., *161*, 1925, 9; Stapp and Zycha, Arch. f. Mikrobiol., *2*, 1931, 493; Zycha, Arch. f. Mikrobiol., *3*, 1932, 194; Patrick, Iowa State Coll. Jour. Sci., *7*, 1933, 407.

10. **Bacillus macerans** Schardinger. (Rottebazillus 1, Schardinger, Wiener klin. Wochenschr., *17*, 1904, 207; Schardinger, Cent. f. Bakt., II Abt., *14*, 1905, 772; *Aerobacillus macerans* Donker, Inaug. Diss., Delft, 1926, 139; *Zymobacillus macerans* Kluyver and Van Niel, Cent. f. Bakt., II Abt., *94*, 1936, 402.) From Latin *macerans*, softening, macerating or retting.

Porter, McCleskey, and Levine, Jour. Bact., *33*, 1937, 163, regard the following as a synonym of *Bacillus macerans*: *Bacillus acetoethylicum* Northrup, Ashe, and Senior, Jour. Biol. Chem., *39*, 1919, 1 (*Aerobacillus acetoethylicus* Donker, *loc. cit.*).

The following is probably a variant of

Bacillus macerans: *Aerobacillus schuylkilliensis* Eisenberg, Jour. Amer. Water Works Assoc., *34*, 1942, 365. It is said to differ from *Bacillus macerans* in that sorbitol is not fermented, hydrogen sulfide is produced and gelatin is liquefied.

Spores: Ellipsoidal, 1.0 to 1.5 by 1.5 to 2.5 microns, terminal to subterminal; wall thick and stainable.

Sporangia: Swollen terminally, clavate.

Rods: 0.6 to 1.0 by 2.5 to 6.0 microns, occurring singly or in pairs, cells are larger on sugar media than on sugar-free media, and contain a few small fat globules. Motile. Gram-variable.

Gelatin stab: Liquefaction variable (see optimum temperature). Gelatin is hydrolyzed as determined by the Frazier technic (30°C).

Agar colonies: Small, thin, transparent to whitish, irregular, usually smooth.

Agar slant: Growth moderate, spreading, inconspicuous.

Broth: Turbid, slight sediment. In sugar broths some strains produce slime. Glucose broth cultures, pH 5.0 to 5.5.

Milk: Acid and gas. No visible peptonization.

Milk agar plate: Casein not hydrolyzed in one week; later usually slight hydrolysis.

Potato: Growth indistinct, gas is formed and the potato is digested. Fruity odor sometimes produced.

Nitrites produced from nitrates.

Starch is hydrolyzed.

Acid and gas from arabinose, rhamnose, xylose, glucose, fructose, galactose, mannose, sucrose, maltose, lactose, trehalose, cellobiose, raffinose, melezitose, dextrin, inulin, salicin, pectin, xylan, glycerol, mannitol, and sorbitol. Erythritol, adonitol, dulcitol, and inositol not fermented (Porter, McCleskey, and Levine, *loc. cit.*).

Produces acetone and ethyl but never butyl alcohol; ratio acetone to alcohol is 1:2.

Acetylmethylcarbinol not produced.

Citrates not utilized as sole source of carbon.

Optimum temperature about 37°C. Good growth at 42° to 45°C and sometimes slightly higher; poor growth, if any, at 20°C.

Differentiated from *Bacillus polymyxa* by the production of crystalline dextrins from starch, lack of formation of acetylmethylcarbinol, and by growth at 42°C to 45°C.

All strains agglutinated by homologous sera but not by *Bacillus polymyxa* serum.

Aerobic, facultative.

For additional literature, see Porter, McCleskey and Levine, Jour. Bact., *33*, 1937, 180.

Source: Originally isolated from vats in which flax was retting.

Habitat: Widely distributed in soil, water, decomposing starchy materials, retting flax, etc.

11. **Bacillus circulans** Jordan. (Jordan, Exp. Inv., Mass. State Board Health, Part II, 1890, 831; *Bacterium circulans* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 92; also see Ford, Jour. Bact., *1*, 1916, 519.) From Latin *circulans*, making round or circular.

Smith, Gordon, and Clark (*loc. cit.*) consider *Bacillus circulans* as a complex (see also Gibson and Topping, Soc. Agric. Bact. (British), Abstr. Proc., 1938, 43) because of the variations in the character of the growth and quantitative differences in physiology. All stages of growth may be found from the smooth actively motile strains that have motile colonies to the mucoid, non-spreading strains. The species is more saccharolytic than proteolytic, considerable variation being found in its action on gelatin and casein. The following are regarded as variants: *Bacillus closteroides* Gray and Thornton, Cent. f. Bakt., II Abt., *73*, 1928, 93; Bewegungstypus schwarmender Bakterien, Russ-Munger, Cent. f. Bakt., I Abt., Orig., *142*, 1938, 175; *Bacillus krzemieniewski*

Kleczkowska, Norman and Snieszko, Soil Sci., *49*, 1940, 185 (a mucoid variant).

Also probable variants: *Bacillus platus* Soriano, Thesis, Univ. Buenos Aires, 1935, 572; *Bacillus naviformis* Soriano, *ibid.*, 574 (not *Bacillus naviformis* Jungano, Comp. rend. Soc. Biol., Paris, *1*, 1909, 122).

Spores: Ellipsoidal, 0.8 to 1.2 by 1.1 to 2.0 microns, terminal or subterminal. Spore wall thick and stainable. In some strains spores may be kidney-shaped and remnants of sporangium may adhere.

Sporangia: Swollen terminally, clavate.

Rods: 0.5 to 0.9 by 2.0 to 5.0 microns, sometimes curved, usually occurring singly. Cells contain small fat globules when grown on glucose agar. Motile, some strains exceedingly so. Gram-variable, usually negative.

Gelatin stab: Slow cone-shaped liquefaction, liquefied portion evaporating (Jordan); no liquefaction (Ford). Gelatin hydrolyzed if tested by the Frazier method.

Agar colonies: Thin, transparent, spreading over entire surface of plate. Often nearly invisible. The colonies of the rougher or mucoid strains are small, entire, whitish, non-spreading.

Giant agar colonies: If the surfaces of agar plates are dried before inoculation with very motile strains, instead of spreading as a thin layer of individual cells, minute rotating colonies proceed out from the edge of the colony, sometimes becoming entirely disconnected from it. In moving out across the agar surface, non-motile cells are left behind. These may grow later. Eventually the whole plate is covered.

Agar slant: Growth thin, transparent, spreading, becoming denser. Mucoid strains are dense, non-spreading, entire, gummy and adherent.

Broth: Light to fair turbidity with flocculent to slimy sediment. Some strains do not grow perceptibly. In glucose broth cultures the final pH is usually 5.0 to 5.8.

Milk: Usually acid, slowly coagulated.

Milk agar plate: Casein not hydrolyzed. Weak hydrolysis with some strains.

Potato: Growth is very variable, from none to good growth, from colorless to yellowish, pink, or brownish.

Nitrites usually produced from nitrates.

Starch is hydrolyzed. Crystalline dextrins usually not formed.

Acid without gas (with ammoniacal nitrogen) from glucose, fructose, mannose, galactose, sucrose, maltose, raffinose, salicin, and dextrin. Usually acid from arabinose, xylose, lactose, glycerol, and mannitol. Reaction variable with rhamnose and inulin.

Acetylmethylcarbinol not produced.

Citrates usually not utilized.

Methylene blue reduced and then reoxidized.

Urease produced by some strains.

Optimum temperature about 30°C. Maximum temperature allowing growth, 40°C to 48°C. A few strains will grow up to 52°C.

This species is closely related to *Bacillus macerans* from which it is distinguished by the lack of gas formation from carbohydrates and the lack of crystalline dextrins from starch. It is also close to *Bacillus alvei* as indicated by the key.

Source: Found occasionally in tap water, Lawrence, Mass. (Jordan).

Habitat: Widely distributed in soil, water, and dust.

12. **Bacillus alvei** Cheshire and Cheyne. (Jour. Roy. Mic. Soc., Ser. II, *5*, 1885, 592.) From Latin *alveus*, beehive.

Probably identical with the above: *Bacillus paraalvei* Burnside, Amer. Bee Jour., *72*, 1932, 433; Burnside and Foster, Jour. Econ. Entomol., *28*, 1935, 578.

Spores: Ellipsoidal, 0.7 to 1.0 by 1.5 to 2.5 microns, central to terminal. Free spores frequently lie in parallel arrangement like the rods.

Sporangia: Swollen, spindle-shaped to clavate.

Rods: 0.5 to 0.8 by 2 to 5.0 microns. Cells frequently lie parallel, side by side, like cartridges in a clip. Usually non-capsulated and very motile. Few small fat globules in cells from glucose agar. Gram-variable (young cells Gram-positive, becoming Gram-negative).

Gelatin stab: Slow liquefaction.

Agar colonies: Thin, translucent, smooth, quickly spreading as a thin layer over entire plate. The growth thickens with age. Rough and mucoid strains do not spread.

Giant agar colonies: If the surfaces of agar plates are dried before inoculation with the motile strains, instead of spreading as a thin layer, minute bullet-shaped colonies proceed out from the edge of the colony and move across the sterile agar. Non-motile and sometimes motile cells are left behind along the path made by the motile colony (Smith and Clark, Jour. Bact., *35*, 1938, 59). Eventually the whole plate is covered.

Agar slant: Growth thin, inconspicuous, spreading, becoming thicker. Rough and mucoid strains do not spread, growth is heaped, and sometimes gummy.

Broth: Uniform turbidity. Rough strains may form a pellicle. Glucose broth cultures have a pH of 5.0 to 6.0.

Milk: Usually coagulated, little or no acid, peptonized.

Milk agar plate: Casein hydrolyzed.

Potato: Growth scant to moderate, soft, spreading, usually creamy yellow.

Nitrites not produced from nitrates.

Starch is hydrolyzed.

Acid (with ammoniacal nitrogen) from glucose, fructose, galactose, sucrose, maltose, dextrin and glycerol. Reaction variable on mannose, lactose, raffinose, salicin, and mannitol. No acid from arabinose, rhamnose, xylose, and inulin.

Acetylmethylcarbinol is produced.

Citrates not utilized.

Optimum temperature about 30°C. Maximum temperature allowing growth 43°C to 45°C.

Putrefactive odor on media rich in proteins (egg).

Aerobic.

Source: Isolated from diseased brood of bees.

Habitat: Associated with European foulbrood of honey bees; widely distributed in soil.

NOTE: The following must be considered in connection with *Bacillus alvei*:

Bacillus pluton White. (U. S. Dept. of Agric., Bur. Entomol., Circ. 157, 1912; *Diplococcus pluton* Bergey et al., Manual, 2nd ed., 1925, 45.)

See also Lochhead, Science, *67*, 1928, 159 and Proc. IV Intern. Congr. Entomol., *2*, 1929, 1005; Burnside, Jour. Econ. Entomol., *27*, 1934, 656; Tarr, Ann. Appl. Biol., *24*, 1935, 614; Burri, Beihefte z. schweiz. Beinenz., *1*, Heft 1, 1941.

White considered *Bacillus pluton* to be the cause of European foulbrood though the evidence was indirect since the organism was not cultivated. Lochhead suggested that *Bacillus pluton* and *Streptococcus apis* are variants or stages in the life history of *Bacillus alvei*, a hypothesis supported by Burnside who included, in addition, *Bacterium eurydice*. According to Burri, rod forms identical with *Bacterium eurydice* give rise to *Bacillus pluton* which is not directly cultivable. Tarr considers European foulbrood to be caused by *Bacillus pluton*, distinct from *Bacillus alvei*, and considers it a strict parasite able to multiply only in the intestines of young larvae.

Source: Larvae of the honey bee infected with European foulbrood.

13. **Bacillus laterosporus** Laubach. (Jour. Bact., *1*, 1916, 511.) From Latin *latus*, *lateris*, the side; Greek *sporus*, seed; M.L., spore.

Synonym: *Bacillus orpheus* White. (U. S. Dept. of Agric., Bur. Entomol., Circ. 157, 1912, 3.) Although named by White, the organism was not described

until 1917 (McCray, Jour. Agr. Research, 8, 1917, 410). Resembles *Bacillus laterosporus* (White, U. S. Dept. Agric. Bull. 810, 1920, 14). According to the rules of priority, the name to be used is *Bacillus laterosporus*.

Spores: Ellipsoidal, 1.0 to 1.3 by 1.2 to 1.5 microns, central to subterminal, formed close to one side, remnants of the sporangium adhering to the other side.

Sporangia: Swollen, spindle-shaped.

Rods: 0.5 to 0.8 by 2.0 to 5.0 microns, occurring singly and in pairs. Ends pointed or poorly rounded. Cells from glucose nutrient agar may have few small fat globules. Motile. Gram-variable.

Gelatin stab: Slow liquefaction.

Agar colonies: Thin, transparent, irregular, spreading. Colonies of rough strains are small, round, convex, non-spreading.

Agar slant: Growth moderate, flat, translucent to opaque, moist, sometimes with a silvery sheen.

Broth: Uniform to granular turbidity; usually no pellicle. Glucose broth cultures, pH 6.0 to 6.4.

Milk: Usually curdled, peptonized.

Milk agar plate: Occasionally weak hydrolysis of casein.

Potato: Growth thin, spreading, grayish to pinkish, turning light brown with age. Sometimes finely wrinkled.

Nitrites produced from nitrates.

Starch is not hydrolyzed.

Acid (with ammoniacal nitrogen) from glucose, fructose, maltose, glycerol, and mannitol. Reaction variable on galactose, mannose, and salicin. No acid from arabinose, rhamnose, xylose, sucrose, lactose, raffinose, inulin, and dextrin.

Acetylmethylcarbinol not produced.

Citrates not utilized as sole source of carbon.

Optimum temperature about 28°C. Maximum temperature allowing growth 37°C to 45°C.

Aerobic.

Source: Isolated from water.

Habitat: Widely distributed in soil, water and dust.

14. **Bacillus brevis** Migula *emend.* Ford. (Bacillus No. I, Flügge, Ztschr. f. Hyg., *17*, 1894, 294; *Bacillus lactis* No. I, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 208; Migula, Syst. d. Bakt., *2*, 1900, 583; not *Bacillus brevis* Frankland and Frankland, Microorganisms in Water, 1894, 429; *Bacillus flüggei* Chester, Man. Determ. Bact., 1901, 281; Ford, Jour. Bact., *1*, 1916, 522.) From Latin *brevis*, short.

Synonym: *Bacillus centrosporus* Ford, Jour. Bact., *1*, 1916, 524.

There is some doubt as to the identity of Migula's *Bacillus brevis* which originally was Flügge's Bacillus No. I. Neide (Cent. f. Bakt., II Abt., *12*, 1904, 337) also renamed Flügge's organism. He called it *Bacillus lactis* and described it sufficiently that it may be recognized as a strain of *Bacillus cereus*. Ford believed that his isolations from milk, soil and dust conformed to Migula's description of *Bacillus brevis*. Ford's interpretation has been accepted. The species has apparently become well established in Europe (Gibson and Topping, Soc. Agric. Bact. (British), Abstr. Proc., 1938, 43) as well as in America.

Description from Ford and from Smith, Gordon, and Clark (*loc. cit.*).

Spores: Ellipsoidal, 1.0 to 1.3 by 1.5 to 2.0 microns, central to subterminal. Spore walls thick and stainable. An occasional strain shows the relationship of this species to *Bacillus laterosporus* in that some of the spores may be lateral and remnants of the sporangia may adhere to one side of the spore.

Sporangia: Definitely swollen, spindle-shaped to clavate.

Rods: 0.4 to 0.8 by 1.5 to 5.0 microns, with pointed ends, occurring singly or in pairs. On glucose agar cells contain numerous small fat globules. Motile. Gram-variable.

Gelatin stab: Slow liquefaction.

Agar colonies: Thin, flat, translucent, smooth, quickly spreading over plate.

Agar slants: Growth smooth, moist, spreading, grayish white.

Broth: Usually heavy uniform turbidity, sometimes with a fragile pellicle. Glucose broth cultures have a pH of 8.0 to 8.6 after 7 days.

Milk: Peptonized.

Milk agar plate: Casein hydrolyzed.

Potato: Growth scant to moderate, flat, spreading, soft, creamy-yellow to pink to brownish.

Nitrites usually formed from nitrates.

Starch is not hydrolyzed.

Acid (with ammoniacal nitrogen) from glucose, fructose, maltose, and sucrose. Usually acid from galactose and glycerol. Reaction is variable on rhamnose and mannitol. No acid from arabinose, xylose, mannose, lactose, raffinose, inulin, dextrin and salicin.

With organic nitrogen, the acid formed from carbohydrates is masked by the alkalinity due to proteolysis.

Acetylmethylcarbinol is not produced.

Citrates usually utilized as a sole source of carbon.

Optimum temperature about 30°C. Maximum temperature allowing growth varies from 43°C to 54°C.

Produces antibiotic substances (tyrothricin, gramicidin; see Dubos and Hotchkiss, Jour. Exp. Med., *73*, 1941, 629).

Aerobic.

Source: From milk (Flügge); from milk, soil and dust (Ford).

Habitat: Widely distributed in soil, water, dust, milk, etc.

15. **Bacillus larvae** White. (Bacterium X, Moore and White, New York State Dept. Agr., 11th Ann. Rept. Com. Agr. for 1903, 1904, 111; Bacillus X, Moore and White, *ibid.*, Rept. for 1904, 1905, 106; White, Thesis, Cornell Univ., Ithaca, N. Y., 1905; White, U. S. Dept. Agr. Bur. Entomol., Tech. Ser. Bul. 14, 1906, 32; White, U. S. Dept. Agr. Bul. 809, 1920, 13.) From Latin *larva*, a ghost; M. L., of a larva.

Synonyms: *Bacillus brandenburgiensis* Maassen, Mittl. a. d. kaiserl. biol. Anstalt f. Land- u. Forstw. in Dahlem, Heft 2, 1906, 28; *ibid.*, Heft 7, 1908, 24 pp.; Arb, a. d. Anstalt f. Land- u. Forstw., *6*, 1908. 61; *Bacillus burri* Cowan, British Beekeeper's Guide Book. 20th ed., London, 1911, 171.

Description from Lochhead, Sci. Agr., *9*, 1928, 84.

Spores: Ellipsoidal, central to subterminal.

Sporangia: Swollen, spindle form.

Rods: 0.5 to 0.8 by 2.5 to 5.0 microns, occurring singly and in chains. Motile. Gram-variable.

Gelatin stab: No growth. In carrot-gelatin, slow liquefaction.

Yeast-carrot agar colonies: Small, whitish, somewhat transparent, smooth, slightly glistening.

Agar slant: No growth. With addition of carrot extract, noticeable growth along line of inoculation. More abundant growth if yeast extract is also added.

Yeast-carrot broth: Fungoid in appearance, floating masses which may be broken up by shaking to produce a uniform clouding.

Carrot-milk: Acid with curdling. No peptonization.

Potato: No growth.

Nitrites formed from nitrates (see Lochhead, Can. Jour. Res., C, *15*, 1937, 79).

Starch not hydrolyzed (carrot-starch agar).

Acid (in yeast extract-peptone broth) from xylose, glucose, fructose, galactose, salicin. Slight acidity by some strains from lactose and sucrose. No acid from mannitol or dulcitol.

Thiamin replaces the growth factor in vegetable or yeast extracts, etc. (Lochhead, Jour. Bact., *44*, 1942, 185).

Optimum temperature about 37°C. Maximum temperature about 45°C.

Source: From diseased brood.

Habitat: Causal organism of American foulbrood of honey bees.

See in addition: White, Science, *49*, 1919, 362; Sturtevant, Jour. Agr. Res., *28* 1924, 129; Borchert, Die seuchenhaften Krankheiten der Honigbiene. Berlin,

1926; Sturtevant, Jour. Agr. Res., *45*, 1932, 257; Hitchcock, Jour. Econ. Entomol., *29*, 1936, 895; Stoilowa, Cent. f. Bakt., II Abt., *99*, 1938, 124; Tarr, Ann. Appl. Biol., *25*, 1938, 633; Holst and Sturtevant, Jour. Bact., *40*, 1940, 723.

16. **Bacillus popilliae** Dutky. (Jour. Agr. Research, *61*, 1940, 59.) From the genus name of the Japanese beetle, *Popillia japonica* Newm.

Spores: Cylindrical, 0.9 by 1.8 microns, central. Free spores have not been observed.

Sporangia: Swollen, spindle-shaped. Contains a refractile body at the broader pole of the cell which is about half the size of the spore and reacts similarly to stains.

Rods: Unstained, 0.9 by 5.2 microns. Stained by crystal violet after fixing in Schaudinn's solution, 0.3 by 3.5 microns. Non-motile. Gram-positive.

Unheated egg yolk-beef infusion agar slants: Growth occurs as small discrete colonies.

Optimum temperature about 30°C. Maximum temperature about 36°C.

Aerobic, facultative.

Source: From infected larvae.

Habitat: Cause of type A milky disease of Japanese beetle, *Popillia japonica*. See Hawley and White, N. Y. Ent. Soc. Jour., *43*, 1935, 405.

17. **Bacillus lentimorbus** Dutky. (Jour. Agr. Res., *61*, 1940, 65.) From Latin *lentus*, slow, lingering, and *morbus*, death.

Spores: Ellipsoidal, 0.9 by 1.8 microns, central.

Sporangia: Swollen, spindle-shaped. No refractile granule at pole.

Rods: Unstained, 1.0 by 5.0 microns. Stained by crystal violet after fixing in Schaudinn's solution, 0.5 by 4.0 microns. No growth on artificial media.

Optimum temperature about 25°C. Maximum temperature about 30°C.

Aerobic, facultative.

Source: Diseased larvae.

Habitat: Cause of type B milky disease of Japanese beetle, *Popillia japonica*.

18. **Bacillus sphaericus** Neide. (Cent. f. Bakt., II Abt., *12*, 1904, 350.) From Latin *sphaericus*, spherical.

Neide (*loc. cit.*) gave the following as possible synonyms: *Bacillus (Streptobacter) albuminus* Schroeter, in Cohn, Kryptogamenflora von Schlesien, *3*, 1, 1886, 162; *Bacillus putrificus coli* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 303; *Bacillus gracilis* Zimmermann, Die Bakterien unserer Trink- u. Nutzwässer, etc., *1*, 1890, 50 (*Bacterium gracile* Chester, Man. Determ. Bact., 1901, 198); *Bacillus butyricus* Botkin, Ztschr. f. Hyg., *11*, 1892, 421; *Bacillus thalassophilus* Russell, Ztschr. f. Hyg., *11*, 1892, 190; *Bacillus pseudotetanicus aerobius* Kruse, in Flügge, Die Mikoorganismen, 3 Aufl., *2*, 1896, 267 (*Bacillus pseudotetanicus* Migula, Syst. der Bakt., *2*, 1900, 626; not *Bacillus pseudotetanicus* Kruse, *idem;* not *Bacillus pseudotetanicus* Chester, Man. Determ. Bact., 1901, 302; *Bacillus pseudotetanicus* var. *aerobius* Chester, *ibid.*, 303); *Plectridium paludosum* Fischer, Jahr. f. Wiss. Bot., *27*, 1895, 147; Pseudotetanicusbacillus, Tavel, Cent. f. Bakt., I Abt., *23*, 1898, 538 (*Bacillus pseudotetani* Migula, Syst. der Bakt., *2*, 1900, 598; *Bacillus taveli* Chester, *loc. cit.*, 304).

Also apparently identical with *Bacillus sphaericus: Bacillus subtetanicus* Migula, Syst. der Bakt., *2*, 1900, 629; *Bacillus lactimorbus* Jordan and Harris, Jour. Amer. Med. Assoc., *50*, 1908, 1669 (see also Jour. Inf. Dis., *6*, 1909, 465); *Bacillus serositidis* Lacorte, Memorias do Instit. Oswaldo Cruz, *26*, 1932, 1.

There has been considerable confusion over the correct name to be applied to the non-pathogenic aerobic organisms resembling *Clostridium tetani*. Kruse (*loc. cit.*) isolated his cuture of *Bacillus pseudotetanicus aerobius* from a case of human tetanus. It was aerobic at ordinary temperatures but produced spores

only at higher temperatures and under anaerobic conditions. Migula called this *Bacillus pseudotetanicus*. Ford (Jour. Bact., *1*, 1916, 520) stated that this name had priority over Neide's *Bacillus sphaericus* which he thought was identical. On the other hand, Tavel (*loc. cit.*) isolated a pseudotetanus bacillus that was apparently anaerobic. Its spores were ellipsoidal and it formed more gas than the tetanus bacillus. Migula named this organism *Bacillus pseudotetani*. Subsequently both of Migula's names have been applied to the aerobic organism. *Bacillus pseudotetanicus* and *Bacillus pseudotetani* are *nomina dubia* and *Bacillus sphaericus* should therefore be used.

Spores: Spherical, 0.7 to 1.3 microns in diameter, terminal to subterminal. Young spores in sporangia may be oval. Spore wall thick; remnants of sporangium may adhere.

Sporangia: Definitely swollen, clavate to spindle-shaped.

Rods: 0.6 to 1.0 by 1.5 to 7.0 microns, occurring singly or in short chains. On glucose agar cells contain few small fat globules. Motile. Gram-variable; often Gram-negative with Gram-positive granules.

Gelatin stab: Scant growth. No liquefaction. Gelatin hydrolyzed if tested by the Frazier technic.

Agar colonies: Small, thin, flat, translucent, often spreading over the plate.

Giant agar colonies: If the surface of the agar is fairly dry, many strains exhibit minute colonies that swarm out from the point of inoculation and cover the plate (cf. *Bacillus alvei* and *Bacillus circulans*).

Agar slants: Growth thin, smooth, spreading, translucent, becoming yellowish-brown. Growth occurs at pH 6.0.

Broth: Uniform turbidity. Glucose broth cultures have pH of 8.3 to 8.6 after 7 days.

Milk: No change.

Milk agar plate: Scant, if any, hydrolysis of casein.

Potato: Growth scant, thin, spreading, soft, gray, becoming yellowish-brown with age.

Nitrites not formed from nitrates.

Starch not hydrolyzed.

No acid from carbohydrates.

Acetylmethylcarbinol not produced.

Citrates not utilized.

Urease not formed.

Salt tolerant. Growth occurs in broth containing 4 per cent NaCl.

Optimum temperature about 30°C. Maximum temperature allowing growth 40°C to 45°C.

Not pathogenic for guinea pigs.

Aerobic, facultative.

Source: From mud of a pond, rotting cypress wood, rotting oak wood, and from soil.

Habitat: Widely distributed in nature.

Bacillus rotans Roberts (Jour. Bact., *29*, 1935, 229) differs from *Bacillus sphaericus* in that it will not grow as low as pH 6.0 nor in broth containing 4 per cent NaCl. Originally characterized by motile colonies, this phenomenon has been noted with certain other members of the genus and with some strains of *Bacillus sphaericus*. Smith, Gordon, and Clark (*loc. cit.*) consider it a variety of *Bacillus sphaericus*.

Source: From intestine of a termite.

Habitat: Probably widespread in soil.

18a. *Bacillus sphaericus* var. *fusiformis comb. nov.* (*Bacillus fusiformis* Gottheil, Cent. f. Bakt., II Abt., *7*, 1901, 724.) From Latin *fusus*, spindle; *formis*, shape.

This organism differs from *Bacillus sphaericus* only in that it produces urease.

Source: One strain isolated from *Beta vulgaris lutea* (beet). Also from milk, dust, soil and contaminated hirudin.

Habitat: Widely distributed in nature.

Bacillus loehnisii Gibson (Jour. Bact., *29*, 1935, 495) is very closely related to the above. It will not grow at pH 6.0 or below, prefers media containing urea, and produces nitrites from nitrates. Gibson (*loc. cit.*, 500) in discussing the

organisms of this group stated "each species contains strains dissimilar in several features and each is connected to the others by transitional forms". Smith, Gordon, and Clark (*loc. cit.*) tentatively have placed it as a variety of *Bacillus sphaericus*.

Source: From soil.

Habitat: Widely distributed in soil.

19. **Bacillus pasteurii** (Miquel) Chester. (*Urobacillus pasteurii* Miquel, Ann. Micrographie, *1*, 1889, 552; sive *Bacillus ureae α, ibid.*, *2*, 1890, 13, 53, 122, 145, 367, 488; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *10*, 1898, 110.) Named for the French scientist, Louis Pasteur (1822–1895).

Viehover, Cent. f. Bakt., II Abt., *39*, 1913, 209, gave the following as possible synonyms: *Urobacillus maddoxii* Miquel, Ann. Micrographie, *3*, 1891, 275 and 305 (*Bacterium maddoxi* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 98; *Bacillus maddoxi* Chester, *ibid.*, *10*, 1898, 110); *Urobacillus leubei* Beijerinck, Cent. f. Bakt., II Abt., *7*, 1901, 51.

Synonyms according to Gibson, Jour. Bact., *29*, 1935, 494 and 496: *Bacillus probatus* Viehover, Cent. f. Bakt., II Abt., *39*, 1913, 209; *Urobacillus psychrocartericus* and *Urobacillus hesmogenes* Rubentschik, Cent. f. Bakt., II Abt., *66*, 1925, 166 (*Bacillus psychrocartericus* and *Bacillus hesmogenes* Bergey et al., Manual, 3rd ed., 1930, 403, 404). Gibson also included the following as possibly identical with the above although they were incompletely described: *Bacillus ureae II* and *III* Burri, Herfeldt and Stutzer, Jour. Landw., *42*, 1894, 329; *Urobacillus duclauxii* Miquel, Ann. Micrographie, *2*, 1890, 53, 122, and 145; *Urobacillus maddoxii* Miquel, *ibid.*, *3*, 1891, 275 and 305.

Description taken from Löhnis and Kuntze, Cent. f. Bakt., II Abt., *20*, 1908, 684; Gibson, Jour. Bact., *28*, 1934, 295 and 313; Smith, Gordon, and Clark (*loc. cit.*).

This species has been designated as the type species of the genus *Urobacillus* Miquel (Ann. de. Micrographie, *1*, 1889, 517) by Enlows (U. S. Pub. Health Ser., Hyg. Lab. Bull. 121, 1920, 96).

Spores: Spherical, 1.0 to 1.2 microns, terminal to subterminal.

Sporangia: Prevailingly clavate. Not in chains.

Rods: 0.7 to 0.8 by 1.5 to 2.0 microns (1.0 to 1.5 by 4.0 to 5.0 microns, Löhnis and Kuntze), occurring singly or in pairs. Motile. Gram-variable.

Urea gelatin stab: Slow liquefaction.

Urea agar colonies: Small, entire, not characteristic.

Urea agar slope: Growth thin, very little spreading, colorless or white to yellowish. Will not grow at pH 6.0 or less.

Urea broth: Moderate to heavy uniform turbidity. Will grow with 4 per cent NaCl added.

Nitrites produced from nitrates in urea nitrate nutrient broth.

Starch not hydrolyzed.

Carbohydrates not attacked.

Acetylmethylcarbinol not formed.

Urease produced.

Optimum temperature about 30°C, minimum 6°C. Maximum temperature allowing growth 40°C in water bath. Optimum temperature for urease activity 50°C.

Aerobic.

The distinguishing character of this species is that growth occurs only in peptone media containing urea or free ammonia under neutral or alkaline conditions.

Source: From decomposing urine.

Habitat: Widely distributed in soil, dust, manure, and sewage.

20. **Bacillus thermoamylolyticus** Coolhaas. (Cent. f. Bakt., II Abt., *75*, 1928, 344.) From Greek *thermos*, hot, *amylon*, starch, and *lytikos*, able to loose; hence, dissolving. Probably intended to mean thermophilic and starch digesting.

Spores: Slightly elongated, ellipsoids 0.6 by 1.5 microns, central.

Sporangia: Cylindrical, not swollen, not in chains.

Rods: 0.6 by 5 to 8 microns. Motile. Gram-positive.

Gelatin stab: No liquefaction.

Agar colonies: At 60°C of two types, large and small, circular, translucent, granular, slimy.

Broth: Very weak growth, no surface growth, no sediment.

Milk: Not coagulated, slowly peptonized.

Potato: Slight growth.

Nitrites produced from nitrates.

Starch actively hydrolyzed.

Acid and gas from glucose, fructose, galactose, maltose, dextrin, starch and glycerol. Arabinose, xylose and mannitol not fermented

Thermophilic, optimum temperature 50° to 55°C.

Aerobic.

Source: From sewage.

Habitat: Probably in decaying matter.

21. **Bacillus kaustophilus** Prickett. (N. Y. Agr. Exp. Sta. Tech. Bul. 147, 1928, 38.) From Greek *kaustós*, burnt, red-hot; *philos*, loving; heat-loving.

Spores: Ellipsoidal, 0.5 by 0.6 to 0.8 micron, terminal to subterminal. No free spores observed.

Sporangia: Only slightly swollen if at all.

Rods: On yeast extract-nutrient agar at 56°C, 0.7 by 2.0 to 4.5 microns, with rounded ends. Actively motile. Gram-positive.

Gelatin stab: No growth at 20°C. Liquefied at 56°C.

Agar colonies: At 56°C, circular, convex, smooth. Borders entire to irregular. Show curled structure, strands of chains. Brown by transmitted light.

Agar slant: Growth abundant, raised, glistening, contoured, bluish-green to bluish-white by transmitted light. After three weeks at 37°C, growth has a distinct reddish-brown color, butyrous, viscid.

Broth: Slightly turbid, no sediment. No surface growth, alkaline.

Litmus milk: Rennet coagulum, peptonization feeble, litmus reduced.

Potato: Amount of growth variable, brownish, spreading, glistening, slimy. Some strains do not grow.

Nitrites produced from nitrates, often with the production of nitrogen.

Starch is hydrolyzed.

Acid from glucose and salicin. Rhamnose, maltose, sucrose, raffinose, mannitol, sorbitol and inulin not fermented.

Acetylmethylcarbinol not produced.

Thermophilic, optimum temperature 60°C to 65°C. Growth at 73°C to 75°C but none at 80°C on agar slants.

Aerobic, facultative.

Good growth occurs in synthetic media containing potassium nitrate, sodium ammonium phosphate, aspartic acid, and sodium asparaginate, respectively, as only sources of nitrogen with glucose as source of carbon.

Source: Forty-eight cultures isolated from pasteurized milk at a single milk plant (Buffalo, N. Y.).

Habitat: Probably originally from soil and dust.

Thermobacillus digestans Feirer (Soil Sci., *23*, 1927, 50) seems to be closely related to the preceding. It is more strongly proteolytic, digesting milk completely in 7 days.

Source: Four strains isolated from soil.

21a. *Bacillus pepo* Shaw. (Jour. Inf. Dis., *43*, 1928, 473.) From *Cucurbita pepo*, the pumpkin.

From the brief original description, this organism seems to vary from *Bacillus kaustophilus* only in its distinctive viscid or slimy character.

Source: Two cultures isolated from swelled cans of pumpkin.

Habitat: Probably found in soil and dust.

22. **Bacillus thermoindifferens** Weinzirl. (Jour. Med. Research, *39*, 1919, 402.) From Greek *thermos*, hot and Latin *indifferens*, indifferent. Indifferent to or tolerant of heat.

Spores: Ellipsoidal, 0.5 by 0.8 micron, terminal.

Sporangia: Cylindrical, not swollen.

Rods: 0.7 by 2.0 to 4.5 microns, occurring singly and in short chains, with rounded ends. Motile. Gram-positive.

Gelatin stab: Growth filiform. Slow infundibuliform liquefaction.

Agar colonies: Circular, convex, smooth, entire, amorphous.

Agar slant: Growth flat, spreading, glistening, translucent, butyrous, contoured.

Broth: Turbid, abundant sediment. No surface growth.

Litmus milk: Alkaline. Litmus reduced.

Potato: No growth.

Indole not formed.

Nitrites not produced from nitrates.

Starch is hydrolyzed.

Acid from glucose. No acid from lactose, sucrose or mannitol.

Thermophilic, optimum temperature 55°C. Grows at 20° to 37°C.

Aerobic.

Source: Isolated from canned pumpkin.

Habitat: Probably found in soil and dust.

Thermobacillus reductans Feirer (Soil Sci., *23*, 1927, 51) is said to resemble *Bacillus thermoindifferens* except that nitrites are formed from nitrates and the minimum temperature is 40°C.

Source: Two strains isolated from soil.

Thermobacillus catenatus Feirer (Soil Sci., *23*, 1927, 53) may be related to this group. The description is very incomplete. Its distinctive feature is the production of indole.

Source: Two strains isolated from soil.

23. **Bacillus thermodiastaticus** Bergey et al. (Type 1, Bergey, Jour. Bact., *4*, 1919, 304; Bergey et al., Manual, 1st ed., 1923, 310.) From Greek *thermos*, hot and *diastatikos*, separative; M. L., enzymatic, diastatic; hence diastatic at high temperatures.

Spores: Of less diameter than that of the rods, ellipsoidal, central.

Sporangia: Cylindrical.

Rods: 0.5 to 0.7 by 2 to 3 microns, occurring in chains, with square ends. Motile with peritrichous flagella. Gram-positive.

Gelatin stab: Liquefaction.

Agar colonies: Grayish, spreading, with lobate to fimbriate borders.

Agar slant: Growth thin, limited, bluish-gray.

Broth: Turbid.

Litmus milk: Not coagulated, peptonized.

Potato: Growth slight, grayish.

Nitrites produced from nitrates.

Starch is hydrolyzed.

Thermophilic, optimum temperature 65°C. No growth at 50°C. Growth at 75°C.

Aerobic.

Source: Isolated from dust and contaminated milk.

Habitat: Probably widely distributed in soil and dust.

Thermobacillus diastasius Feirer (Soil Sci., *23*, 1927, 49) differs from *Bacillus thermodiastaticus* only in that nitrites are not formed from nitrates (Feirer).

Source: Two strains isolated from soil.

24. **Bacillus cylindricus** Blau. (Cent. f. Bakt., II Abt., *15*, 1905, 119.) From Greek *kylindrikos*, cylindrical.

Spores: Somewhat elongated, 0.7 to 1.1 by 1.8 to 2.5 microns, terminal. Remnants of sporangium adherent. Germination equatorial and oblique.

Sporangia: Cylindrical or only slightly swollen at end, not in chains.

Rods: On glucose agar at 60°C, 0.8 to 1.1 by 5.0 to 7.5 microns, occurring singly and in pairs. Motile with peritrichous flagella. Cells store glycogen. Gram-positive.

Gelatin stab: No liquefaction.

Glucose agar colonies: Grayish-white, entire to lobed to dentate. By transmitted light yellowish-brown centers with brownish-yellow borders. Finely fibrous structure.

Glucose agar slant: Growth thin, dull, grayish-white.

Litmus milk: Unchanged.

Potato: No growth.

Nitrites not produced from nitrates.

Starch not hydrolyzed.

Thermophilic, optimum temperature 60°C to 70°C.

Source: Isolated from moist field soil in Germany.

Habitat: Probably found in dust and soil.

Bacillus calidus Blau (Cent. f. Bakt., II Abt., *15*, 1905, 134) differs so little from the preceding species that it cannot be considered as distinct.

Source: Isolated from field soil in Germany (Blau). Dust, ground feeds, etc., about dairies and various dairy products (Prickett, N. Y. Agr. Exp. Sta. Tech. Bul. 147, 1928, 45).

25. **Bacillus robustus** Blau. (Cent. f. Bakt., II Abt., *15*, 1905, 126.) From Latin *robustus*, oaken, hard, firm.

Spores: Ellipsoidal, 1.0 by 1.6 to 2.2 microns, polar to medial. Remnants of sporangium not adherent. Germination prevailingly equatorial.

Sporangia: Ellipsoidal to cylindrical, not in chains.

Rods: 1.0 to 1.2 by 3 to 4 microns, occurring singly and in short chains. Motile. Gram-positive.

Glucose agar colonies: Circular, gray-white. By transmitted light brownish-yellow. Borders distinct, serrate to lobed, finely granular.

Glucose agar slant: Growth yellowish-white, translucent, becoming grayish-white, spreading, dull.

Potato: Growth yellowish-white, moist, glistening, smooth.

Nitrites not produced from nitrates.

Starch not hydrolyzed.

Thermophilic, optimum temperature 55°C to 60°C. Grows at 65°C.

Aerobic.

Source: Isolated from field soil near a forest in Germany.

Habitat: Probably found in soil and dust.

Thermobacillus restatus Feirer (Soil Sci., *23*, 1927, 51) is said to correspond in some respects with *Bacillus robustus*. Feirer states that it is not possible to definitely establish the identity because Blau failed to record the action of *Bacillus robustus* on nitrates and several other media and did not note the production of H_2S.

Source: Three strains isolated from soil.

25a. *Bacillus losanitchii* Bergey et al. (*Bacillus thermophilus losanitchii* Georgevitch, Cent. f. Bakt., II Abt., *27*, 1910, 164; Bergey et al., Manual, 1st ed., 1923, 313.) Named for Losanitch, near Vranje.

As far as can be determined from the meager description, this organism does not differ from *Bacillus robustus* except perhaps as to the maximum temperature allowing growth. Growth limits are 45°C to 78°C.

Source: Isolated from water of hot sulfur spring. Temperature of water 83°C.

Habitat: Probably in natural hot waters.

NOTE: Georgevitch (Arch. f. Hyg., *72*, 1910, 201) has described a thermophilic aerobic spore-forming sulfur bacillus from a hot sulfur spring at Vranje (Servia) under the name *Bacillus thermophilus vranjensis*. This does not grow on ordinary media unless sulfur compounds are added. It has a tuft of flagella at either end. Spores are ellipsoidal, terminal, distend the rod, and show polar germination.

Georgevitch (Cent. f. Bakt., II Abt., *27*, 1910, 150) describes a second thermophilic, motile, capsulated, ellipsoidal-spored rod from a chalybeate hot spring near Vranje under the name *Bacillus thermophilus jivoini*.

26. **Bacillus calidolactis** Hussong and Hammer. (Jour. Bact., *15*, 1928, 186.) From Latin *calidus*, warm, hot and *lac*, *lactis*, milk.

Gorini states (R. Ist. Lombardo Sci. e Lett. Rend., *76*, 1942, 3) that *Bacillus*

calidolactis is the same organism as *Bacillus lactis termophilus* (sic) Gorini (Giorn. d. R. Soc. Ital. d'Igiene, *16*, 1894, 16). From the descriptions this appears to be probable.

Spores: Ellipsoidal, of slightly greater diameter than the rods, terminal.

Sporangia: Slightly swollen, clavate.

Rods: 0.7 to 1.4 by 2.6 to 5.0 microns, occurring singly, in pairs and short chains. Non-motile. Gram-positive, some cells becoming Gram-negative with age.

Gelatin stab: No liquefaction.

No growth on plain nutrient agar.

Glucose agar colonies: Thin, white, opaque, filamentous.

Glucose agar slant: Growth abundant, echinate, dull, white.

Glucose agar stab: Growth abundant, beaded, gray.

Glucose broth: Turbid.

Litmus milk: Acid, coagulation. Litmus reduced.

Potato: No growth.

Nitrites produced from nitrates by some strains.

Acid from glucose, lactose, fructose, galactose and maltose. No acid from inulin, sucrose or glycerol.

Thermophilic, optimum temperature 55°C to 65°C. No growth at 37°C.

Aerobic, facultative.

Source: Isolated from normal pasteurized skim milk (Hussong and Hammer). Milk and milk powder (Prickett, N. Y. Agr. Exp. Sta. Tech. Bul. 147, 1928, 47).

Habitat: Probably in dairy products.

27. **Bacillus michaelisii** Prickett. (*Bacillus thermophilus aquatilis liquefaciens* Michaelis, Arch. f. Hyg., *36*, 1899, 285; Prickett, N. Y. Agr. Exp. Sta. Tech. Bul. 147, 1928, 45.) Named for Georg Michaelis of Berlin who first isolated the species.

Spores: Of greater diameter than the rods, terminal.

Sporangia: Swollen, clavate.

Rods: 0.6 to 0.8 by 2 to 4 microns. Motile. Gram-positive.

Gelatin stab: Liquefaction.

Agar colonies: Circular, raised, smooth, glistening.

Agar slant: Growth moderate, smooth, glistening.

Broth: Slight turbidity.

Milk: Not coagulated, alkaline.

Potato: Growth moist, glistening, yellowish, becoming brownish.

Nitrites with gas produced from nitrates.

Starch is hydrolyzed.

Acid from glucose and sucrose. No acid from rhamnose, maltose, lactose, glycerol, mannitol or inulin.

Thermophilic, optimum temperature 50°C to 60°C.

Aerobic, facultative.

Source: Isolated from fountain waters (Michaelis). From fodder, dust, dairy utensils (Prickett).

Habitat: Probably found in soil and dust.

27a. *Bacillus lobatus* Bergey et al. (Type 3, Bergey, Jour. Bact., *4*, 1919, 304; Bergey et al., Manual, 1st ed., 1923, 311.) From Greek *lobatos*, having the form of a lobe.

Judging from the meager description, there is no essential difference between this organism and the preceding.

Source: Isolated from dust, soil, and horse manure.

Habitat: Probably widely distributed in soil and decaying matter.

Bacillus nondiastaticus Bergey et al. (Type 2, Bergey, Jour. Bact., *4*, 1919, 304; Bergey et al., Manual, 1st ed., 1923, 310.) From Greek, no diastase.

The description of this organism is practically identical with *Bacillus lobatus*, the only difference noted being that this species hydrolyzes starch while *Bacillus nondiastaticus* does not.

Source: Isolated from dust and soil (Bergey). Ground grains, raw and pasteurized milk (Prickett, N. Y. Agr. Exp. Sta. Tech. Bul. 147, 1928, 47).

Thermobacillus vulgaris Feirer (Soil Sci., *23*, 1927, 50) liquefies gelatin, does

not reduce nitrates to nitrites nor alter litmus milk. According to Feirer it is otherwise similar to *Bacillus nondiastaticus*.

Source: Two strains isolated from soil.

27b. *Bacillus thermononliquefaciens* Bergey et al. (Type 4, Bergey, Jour. Bact., *4*, 1919, 304; Bergey et al., Manual, 1st ed., 1923, 312.) From Greek *thermos*, hot; and Latin *non*, not and *liquefaciens*, making liquid. Probably intended to mean thermophilic and non-gelatin-liquefying.

Aside from the non-liquefaction of gelatin, there seems to be no difference in the description of this organism and the two immediately preceding.

Source: Isolated from dust, soil, and horse manure.

Habitat: Probably found in soil and decaying matter.

28. **Bacillus thermotranslucens** Bergey et al. (Type 5, var. b, Bergey, Jour. Bact., *4*, 1919, 304; Bergey et al., Manual, 1st ed., 1923, 312.) From Greek *thermos*, hot and Latin *translucens*, translucent. Probably intended to mean thermophilic and translucent.

Spores: Of larger diameter than the rods, terminal.

Sporangia: Terminally swollen, clavate, not in chains.

Rods: 0.3 to 0.4 by 1.0 to 1.5 microns, occurring singly. Motile with peritrichous flagella. Gram-positive.

Gelatin stab: No liquefaction.

Agar colonies: Thin, transparent, spreading widely.

Agar slant: Growth thin, spreading, veil-like.

Broth: Turbid.

Litmus milk: Not coagulated, slightly acid.

Potato: No growth.

Nitrites not produced from nitrates.

Starch slightly hydrolyzed.

Thermophilic, optimum temperature 60°C. Slight growth at 37°C. No growth at 70°C.

Aerobic.

Source: Isolated from guinea pig feces, dust and from cheese.

Habitat: Probably found in soil and decaying matter.

Thermobacillus linearius Feirer (Soil Sci., *23*, 1927, 53) is said to be similar in some respects to the preceding. Feirer states that formation of acid from several sugars is the distinctive feature of this species, a character not mentioned by Bergey.

Source: Five strains isolated from soil.

28a. *Bacillus stearothermophilus* Donk. (Jour. Bact., *5*, 1920, 373.) From Greek *stéār*, tallow and *thermophilos*, heat-loving. Intended meaning obscure.

From the descriptions, the vegetative rods of this organism seem to be slightly larger than the preceding, otherwise no difference is noted.

Source: Isolated from samples of spoiled canned corn and string beans.

Habitat: Probably found in soil and dust.

28b. *Bacillus aerothermophilus* Weinzirl. (Jour. Med. Research, *39*, 1919, 403.) From Greek *aeros*, air and *thermophilus*, heat-loving. Probably intended to mean aerobic and thermophilic.

There is nothing in the original account of this organism which is at variance with that of the preceding.

Source: Isolated from canned string beans (Weinzirl). From milk, water, hay, dust, beef extract, and agar (Prickett, N. Y. Agr. Exp. Station Tech. Bull. 147, 1928, 46).

Habitat: Probably found in soil and dust.

Thermobacillus alcalinus Feirer (Soil Sci., *23*, 1927, 52) is said to differ from the preceding in that it does not change litmus milk.

Source: Four strains isolated from soil.

Thermobacillus ruber Feirer (Soil Sci., *23*, 1927, 52) apparently is closely related to this group. Its distinguishing character is the production of a pink pigment

in meat, brain, and blood serum, no color on other media.

Source: Isolated from soil.

29. **Bacillus thermocellulolyticus** Coolhaas. (Cent. f. Bakt., II Abt., *76*, 1928, 43.) From Greek *thermos*, hot; and Latin *cellula*, a small room; M. L., cellulose and Greek *lytikos*, dissolving. Probably intended to mean thermophilic and cellulose-digesting.

Spores: Ellipsoidal, 0.8 by 1.5 microns, terminal.

Sporangia: Terminally swollen, clavate.

Rods: 0.3 by 3.5 to 6 microns, occurring singly and in pairs. No reserve material. Non-motile. Gram-positive.

Gelatin stab: No liquefaction.

Glucose agar colonies: Small, glistening, translucent.

Cellulose agar colonies: Circular, borders undulate to lobate.

Broth: Slight growth, no surface growth or sediment.

Milk: No growth.

Nitrites not produced from nitrates.

Starch is hydrolyzed.

No acid from carbohydrates.

Cellulose hydrolyzed.

Thermophilic, optimum temperature 50°C to 55°C. Maximum 60°C to 65°C. Minimum 35°C to 37°C.

Aerobic, facultative.

Source: Isolated from sewage.

Habitat: Probably found in decaying matter.

30. **Bacillus thermoalimentophilus** Weinzirl. (Jour. Med. Research, *39*, 1919, 404.) From Greek *thermos*, hot; Latin *alimentum*, food; and Greek *philos*, loving. Loving hot food.

Spores: Ellipsoidal, 0.8 by 1.0 micron, terminal.

Sporangia: Swollen, clavate, not in chains.

Rods: 0.6 by 3.0 microns, occurring singly, with rounded ends. Motile, flagella not stated. Gram-positive.

Gelatin stab: No growth at 20°C.

Agar colonies: Circular, raised, smooth, amorphous, entire.

Agar slant: Growth spreading to effuse, smooth, glistening, butyrous.

Broth: Turbid, surface ring.

Litmus milk: Unchanged.

Potato: No growth.

Nitrites with gas produced from nitrates.

Starch not hydrolyzed.

Neither acid nor gas from glucose, lactose, sucrose or mannitol.

Thermophilic, optimum temperature 55°C. No growth at 20°C. Growth at 37°C.

Aerobic.

Source: Isolated from canned blueberries (Weinzirl). Pasteurized milk and filter cloth (Prickett, N. Y. Agr. Exp. Sta. Tech. Bul. 147, 1928, 46).

Habitat: Probably found in soil and dust.

Thermobacillus violaceus Feirer (Soil Sci., *23*, 1927, 52) corresponds in some respects with the preceding. Feirer also states that his cultures did not reduce nitrates to nitrites and produced acid on glucose and sucrose.

Source: Four strains isolated from soil.

31. **Bacillus thermoliquefaciens** Bergey et al. (Type 5, var. a, Bergey, Jour. Bact., *4*, 1919, 304; Bergey et al., Manual, 1st ed., 1923, 313.) From Greek *thermos*, hot, and Latin *liquefaciens*, liquefying. Probably intended to mean thermophilic and gelatin-liquefying.

Spores: Ellipsoidal, polar, of greater diameter than the rods.

Sporangia: Terminally swollen, clavate.

Rods: 0.2 to 0.4 by 2 to 3 microns, occurring singly, with rounded ends. Motile with peritrichous flagella. Gram-positive.

Gelatin stab: Liquefaction.

Agar colonies: Moderately dense, lobate.

Agar slant: Growth dense, grayish, lobate to fimbriate margins.

Litmus milk: Coagulated, acid. Litmus reduced.

Potato: No growth.

Nitrites and ammonia produced from nitrates.

Starch not hydrolyzed.

Thermophilic, optimum temperature 60°C. Slight growth at 37°C. No growth at 70°C.

Aerobic.

Source: Isolated from dust, guinea pig feces and horse manure (Bergey). Water and milk (Prickett, N. Y. Agr. Exp. Sta. Tech. Bul. 147, 1928, 47).

Habitat: Probably originally from soil nd dust.

32. **Bacillus tostus** Blau. (Cent. f. Bakt., II Abt., *15*, 1905, 130.) From Latin *tostus*, parched, dried.

Spores: Ellipsoidal, 0.8 to 1.6 by 1.5 to 2.2 microns. Germination prevailingly polar.

Sporangia: Terminally swollen, clavate, not in chains.

Rods: 1.2 by 4.5 to 5.0 microns, occurring in pairs and in short chains. Cells store glycogen. Motile with peritrichous flagella.

Agar colonies: Small, circular, dense. By transmitted light bright yellow to yellowish-brown. Borders sharp, entire to lobate. Older colonies porcelain-like.

Agar slant: Growth thin, grayish-white, spreading, smooth, glistening.

Potato: No growth.

Nitrites not produced from nitrates.

Starch is hydrolyzed.

Ammonia is produced.

Thermophilic, optimum temperature 60°C to 70°C.

Aerobic.

Source: Two cultures isolated from soil in Germany.

Habitat: Probably found in soil and dust.

33. **Bacillus viridulus** (Migula) Bergey et al. (*Bacillus thermophilus II* Rabinowitsch, Ztschr. f. Hyg., *20*, 1895, 154; *Bacterium viridulum* Migula, Syst. der Bakt., *2*, 1900, 343; *Bacterium thermophilum II* Chester, Manual, 1901, 186; ***Bacillus thermophilus*** Bergey et al., Manual, 1st ed., 1923, 315; Bergey et al., Manual, 4th ed., 1934, 464; not *Bacillus thermophilus* Miquel, Ann. d. Microg., *1*, 1888, 6; not *Bacillus thermophilus* Chester, Man. Determ. Bact., 1901, 265.) From Latin, dim. adj. *viridis*, green, somewhat green.

Spores: Spherical, central.

Sporangia: Cylindrical, not swollen.

Rods: Rather large, slightly bent, occurring singly and in pairs. Nonmotile. Gram-positive.

Agar colonies: Irregular, spreading, granular, greenish.

Broth: Alkaline.

Potato: Growth grayish-yellow; margin undulate.

Nitrites not produced from nitrates.

Starch is hydrolyzed.

Thermophilic, grows at 60°C to 70°C. Optimum temperature 62°C. Grows at 33°C.

Aerobic, facultative.

Source: Isolated from soil, snow, feces, corn grains.

Habitat: Probably found in soil and dust.

Appendix: The following additional aerobic spore-forming bacteria are found in the literature. Because of insufficient data it has not been possible to classify them. Some of these may be synonyms of well-known species, some may be varieties, whereas others may actually be separate species.

Aromabacillus weigmanni Omeliansky. (Isolated by Weigmann, 1890; Omeliansky, Jour. Bact., *8*, 1923, 398.) From milk.

Bacillus abysseus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 273.) Subterminal spores. From marine mud.

Bacillus acidifaciens Patrick and Werkman. (Iowa State Coll. Jour. Sci., *7*, 1933, 413.) One of a group characterized by the fermentation of xylan. A single culture isolated from decayed maple wood.

Bacillus acidificans presamigenes casei

Gorini. (Rend. R. Accad. dei Lincei, *8*, 1928, 598.) From manure, fodder and milk. Regarded by Gorini (personal communication, 1925) as identical with *Bacillus circulans* Jordan.

Bacillus acido-proteolyticus casei Gorini. (Le Lait, *9*, 1912, 98.) From Parmesan and Emmenthal cheese. Regarded by Gorini (personal communication, 1925) as equivalent to one of the species of *Tyrothrix* of Duclaux.

Bacillus adametzi Trevisan. (Brauner Wasserbacillus, Adametz and Wichmann, Mittheil. d. oesterr. Versuchsstat. f. Brauerei u. Mälzerei, Wien, Heft 1, 1888, 51; Trevisan, I generi e le specie delle Batteriacee, 1889, 19; not *Bacillus adametzii* Migula, Syst. d. Bakt., *2*, 1900, 686; *Bacillus brunneus* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 142; *Bacterium brunneum* Migula, *ibid.*, 331; not *Bacterium brunneneum* Schroeter, in Cohn, Beitr. z. Biol. d. Pflanz., *1*, Heft 2, 1882, 125.) From water.

Bacillus adhaerens Laubach. (Jour. Bact., *1*, 1916, 503.) One culture isolated from dust.

Bacillus aegyptiacus Werner. (Cent. f. Bakt., II Abt., *87*, 1933, 459.) Good growth on Ca n-butyrate agar. One culture isolated from Egyptian soil.

Bacillus aerifaciens Steinhaus. (Jour. Bact., *42*, 1941, 782.) Author states that it probably belongs to the *Aerobacillus* group. From triturated specimens of the white cabbage butterfly (*Pieris rapae*).

Bacillus aerobius von Wahl. (Cent. f. Bakt., II Abt., *16*, 1906, 496.) Reported to resemble *Bacillus mesentericus fuscus*. From canned peas.

Bacillus aerophilus Flügge. (Flügge, Die Mikroorganismen, 2 Aufl., 1886, 321; *Bacterium aerophilum* Chester, Man. Determ. Bact., 1901, 191.) From dust.

Bacillus afanassieffi Trevisan. (*Bacillus tussis convulsivae* Afanassief, St. Petersburg. med. Wochnschr., 1887, No. 38–42; not *Bacillus tussis convulsivae* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 269; Trevisan, I generi e le specie delle Batteriacee, 1889, 13; *Bacillus pertussis* Migula, Syst. d. Bakt., *2*, 1900, 754.) From mucus and pus.

Bacillus agilis Tschistowitsch. (Tschistowitsch, Berl. klin. Wochnschr., 1892, 512; not *Bacillus agilis* Trevisan, I generi e le specie delle Batteriacee, 1889, 14; not *Bacillus agilis* Chester, Man. Determ. Bact., 1901, 226; not *Bacillus agilis* Mattes, Sitzungsber. d. Gesellsch. z. Beforderung d. gesam. Naturw. z. Marburg, *62*, 1927, 406; not *Bacillus agilis* Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 33.) From pus.

Bacillus agilis Hauduroy et al. (*Bacillus agilis larvae* Toumanoff, Bull. Soc. Cent. de Méd. Vétér., *80*, 1927, 367; Hauduroy, Ehringer, Urbain, Guillot and Magrou, Dictionnaire de Bactéries Pathogènes, Paris, 1937, 33.) Found in foulbrood of bees.

Bacillus agrestis Werner. (Cent. f. Bakt., II Abt., *87*, 1933, 468; not *Bacillus agrestis* de Rossi, Microbiol. agraria e technica, Torino, 1927, 828.) One of a group of species described as being able to grow on a Ca n-butyrate agar. Three cultures were isolated from German and Italian soils.

Bacillus agri Laubach and Rice. (Jour. Bact., *1*, 1916, 516.) Isolated twice from soil in Baltimore.

Bacillus agrophilus Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 189.) Only moderate growth on Ca n-butyrate agar. One culture isolated from soil from Cuba.

Bacillus agrotidis typhoides Pospelov. (Rept. Bur. Appl. Ent., Russian, *3*, 1927, 8.) Found in diseased larvae of the moth, *Euxoa* (*Agrotis*) *segetum*.

Bacillus (*Streptobacter*) *albuminis* Schroeter. (Bacillus aus Faeces V, Bienstock, Ztschr. f. klin. Med., *8*, Heft 1, 1884, 1; Schroeter, in Cohn, Kryptog. Flora v. Schlesien, *3*, 1, 1886, 162; *Bacillus putrificus coli* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 303; *Bacillus diaphthirus* Trevisan, I generi e le specie delle Batteriacee, 1889, 15.) From feces.

Bacillus albus (Sack) Bergey et al. (*Cellulomonas albus* Sack, Cent. f. Bakt., II Abt., *62*, 1924, 79; Bergey et al., Man-

ual, 3rd ed., 1930, 398; not *Bacillus albus* Trevisan, I generi e le specie delle Batteriacee, 1889, 14; not *Bacillus albus* Copeland, Report Filtration Comm., Pittsburgh, 1899, 344.) Cellulose is hydrolyzed. From soil in Germany.

Bacillus alcalophilus Vedder. (Ned. Tijdschr. v. Hyg. Microbiol. en Serolog., *1*, 1934, 141.) Grows only in and on highly alkaline culture media. Sixteen strains isolated from the feces of healthy animals.

Bacillus alopecuri Nogtev. (Botanicheskii Zhurnal, U.S.S.R., *23*, 1938, 149.) Causes nodule formation on fox grass (*Alopecurus pratensis*).

Bacillus alpha Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 366.) From the air.

Bacillus alpinus Werner. (Cent. f. Bakt., II Abt., *87*, 1933, 465.) Good growth on calcium salts of formic, acetic, propionic and butyric acids. One culture isolated from soil from Austria.

Bacillus alveolaris Ksenjoposky. (Review of pests of Volhymia, Volhymia Ent. Bur., Zemstvo of Volhymia, Zitomir, 1916, 24 pp.) From diseased bees (*Apis mellifera*).

Bacillus amarus Hammer. (Iowa Agr. Exp. Station Res. Bull. 52, 1919, 198.) From evaporated milk.

Bacillus aminovorans den Dooren de Jong. (Cent. f. Bakt., II Abt., *71*, 1927, 215.) From soil.

Bacillus amyloaerobius Crimi. (Abst. in Cent. f. Bakt., II Abt., *61*, 1924, 63.) From potato rot.

Bacillus amylolyticus Kellerman and McBeth. (Cent. f. Bakt., II Abt., *34*, 1912, 490.) Decomposes cellulose. One culture isolated from manure.

Bacillus annuliformis Migula. (Fadenähnlicher Bacillus, Maschek, Bakt. Untersuch. d. Leitmeritzer Trinkwässer, Leitmeritz, 1887; Migula, Syst. d. Bakt, *2*, 1900, 783.) From water.

Bacillus anthracis similis McFarland. (Cent. f. Bakt., I Abt., *24*, 1898, 556.) From dust.

Bacillus apicum Canestrini. (Atti Soc. Ven. Trent. Sci. Nat., 91; according to Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 233.) From diseased bees and their larvae.

Bacillus aporrhoeus Fuller and Norman. (Jour. Bact., *46*, 1943, 277.) From soil. Decomposes cellulose.

Bacillus arachnoideus Migula. (Bacillus No. III, Flügge, Ztschr. f. Hyg., *17*, 1894, 294; *Bacillus lactis* No. III, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 208; Migula, Syst. d. Bakt., *2*, 1900, 583; *Bacterium lacteum* Migula, *ibid.*, 321.) From milk.

Bacillus arenarius Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 187.) Good growth on Ca n-butyrate agar. One strain isolated from Cuban soil.

Bacillus aridus Migula. (Bacillus No. 8, Pansini, Arch. f. path. Anat., *122*, 1890, 444; Migula, Syst. d. Bakt., *2*, 1900, 559.) From sputum.

Bacillus arlongii (sic) DeToni and Trevisan. (Bacillus de la septicèmie gangrèneuse, Arloing and Chauveau, see Crookshank, Man. of Bact., 3rd ed., 1890, 305; DeToni and Trevisan, in Saccardo, Sylloge Fungorúm, *8*, 1889, 950.) From wounds in gangrenous septicaemia.

Bacillus asiaticus Sakharoff. (Sakharoff, Ann. Inst. Past., *8*, 1893, 550; not *Bacillus asiaticus* Castellani, Cent. f. Bakt., I Abt., Orig., *65*, 1912, 262.) From feces in a case of cholera.

Bacillus asteris Verona. (Riv. Pat. Veg., *25*, 1935, 15.) Pathogenic for China aster (*Aster chinensis*).

Bacillus asthenogenes Bernard. (Ann. Inst. Past., *35*, 1921, 459.) Grows aerobically as well as anaerobically. Under anaerobic conditions it is said to play a role in gastric derangement and infection commonly confused with beriberi. Author reports that it is very similar to *Bacillus megatherium*.

Bacillus aterrimus tschitensis Klimenko. (Cent. f. Bakt., II Abt., *20*, 1908, 1.) Reported to be like the black potato bacillus except that it forms a black pigment on gelatin and the potato is brown instead of black. From air.

Bacillus aurantius (Sack) Bergey et al.

(*Cellulomonas aurantius* Sack, Cent. f. Bakt., II Abt., *62*, 1924, 78; Bergey et al., Manual, 3rd ed., 1930, 421; not *Bacillus aurantius* Trevisan, I generi e le specie delle Batteriacee, 1889, 19.) From soil.

Bacillus badius Batchelor. (Jour. Bact., *4*, 1919, 25.) From the intestinal tract of children.

Bacillus balcanus Bartels. (Cent. f. Bakt., II Abt., *103*, 1940, 25.) Growth on media containing M/50 phenol. Eight strains isolated from soil.

Bacillus barbitistes Statelov. (Mitt. bulg. ent. Gesells., 7, 1932, 56–61.) From diseased tettigonids (*Isophya* (*Barbitistes*) *amplipennis*).

Bacillus batatae Otani. (Trans. Tottori Soc. Agric. Sci., Japan, *6*, 1939, 222.) From rotten sweet potatoes (*Ipomaea batatas*).

Bacillus bellus Heigener. (Cent. f. Bakt., II Abt., *93*, 1935, 96.) Probably a strain of *Bacillus brevis*. One culture isolated from garden soil of Germany.

Bacillus bernensis Lehmann and Neumann. (Aromabacillus, Burri, Cent. f. Bakt., II Abt., *3*, 1897, 609; Lehmann and Neumann, Bakt. Diag., 2 Aufl., *2*, 1899, 304; *Bacillus odoratus* Migula, Syst. d. Bakt., *2*, 1900, 686; *Bacterium odoratum* Omeliansky, Jour. Bact., *8*, 1923, 394.) From Emmenthal cheese. Reported as producing the aroma of this cheese.

Bacillus beta Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 366.) From dust.

Bacillus betainovorans Heigener. (Cent. f. Bakt., II Abt., *93*, 1935, 94.) Good growth on betaine and valine agar. One culture isolated from soil from Mantua.

Bacillus betanigrificans Cameron, Esty and Williams. (Food Research, *1*, 1936, 75.) From blackened canned beets where juice contains an abnormally high amount of iron.

Bacillus biacutum Soriano. (Revista del Inst. Bacteriol., Univ. Buenos Aires, *6*, 1935, 564.) From soil.

Bacillus bombycis Macchiati. (Des vibrions, Pasteur, Études sur la maladie des vers à soie, La Flacherie, Chapitre II, Paris, 1870; Macchiati, Stazioni sperimentali Agrarie Italiane, *20*, 1891, 121; not *Bacillus bombycis* Chatton, Compt. rend. Acad. Sci., Paris, *156*, 1913, 1708; *Bacillus megaterium bombycis* Sawamura, Tokyo Imp. Coll. Agric. Bull., *6*, 1905, 375.) Pasteur originally isolated this large bacillus from the intestine of silkworms (*Bombyx mori*) suffering from wilt disease. Regarded by Sawamura as a variety of *Bacillus megatherium*.

Bacillus bombycis non-liquefaciens Paillot. (Ann. Épiphyt., *8*, 1922, 131; L'infection chez les insectes, 1933, 288.) Larvae of the gypsy moth (*Lymantria dispar*) are immune to this bacillus.

Bacillus bombycoides Paillot. (Compt. rend. Acad. Agr. France, *28*, 1942, 158.) Causes lesions because of a bacterial toxin. From infected silkworms.

Bacillus bombysepticus Hartman. (Lingnan Sci. Jour., *10*, 1931, 280.) Causes a disease of the silkworm (*Bombyx mori*).

Bacillus borborokoites ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 274.) Central spores. From marine bottom deposits.

Bacillus borstelensis Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 179.) Grows well on Ca n-butyrate agar. Resembles *Bacillus rufescens* of the same group except that it does not show the typical brown coloration of media. Two strains isolated from soils in Germany.

Bacillus bredemannii Chester. (*Bacillus adhaerens* Stührk, Cent. f. Bakt., II Abt., *93*, 1935, 183; not *Bacillus adhaerens* Laubach, Jour. Bact., *1*, 1916, 503; Chester, in Manual, 5th ed., 1939, 675.) Weak growth on Ca n-butyrate agar. One strain isolated from Cuban soil.

Bacillus bronchitidis Migula. (Bacillus der putriden Bronchitis, Lumnitzer, Cent. f. Bakt., *3*, 1888, 621; *Bacillus bronchitidis putridae* Lumnitzer, Wien. med. Presse, 1888, 666; Migula, Syst. d. Bakt., *2*, 1900, 641; *Bacterium lumnitzeri* Chester, Man. Determ. Bact., 1901, 120.)

From sputum in cases of putrid bronchitis.

Bacillus bruneus Migula. (Maschek, Bakt. Untersuch. d. Leitmeritzer Trinkwasser, 1887; Migula, Syst. d. Bakt., *2*, 1900, 835; not *Bacillus brunneus* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 142.) From water.

Bacillus brunneus Eisenberg. (Brauner Wasserbacillus, Adametz and Wichmann, Die Bakt. d. Nutz- u. Trinkwässer, Mitth. Oesterreich. Versuchssta. f. Brauerei u. Mälzerei, Wien, Heft 1, 1888, 51; Eisenberg, Bakt. Diag., 3 Aufl., 1891, 142; not *Bacillus brunneus* Schroeter, in Cohn, Kryptog. Flora v. Schlesien, *3*, 1, 1886, 158; *Bacterium brunneum* Migula, Syst. d. Bakt., *2*, 1900, 331.) From water. Non-motile.

Bacillus butlerovii Serbinow. (Věst. Russ. obšč. pčelovod. (Messager de la Soc. russe d'Apiculture), No. 3 and No. 11, 1912; see Rev. Appl. Entomol., Ser. A, *1*, 1913, 94 and 441.) From black brood of bees.

Bacillus bütschlii Schaudinn. (Arch. f. Protistenkunde, *1*, 1902, 306.) Characterized by its large size (3.0 to 6.0 by 24.0 to 80.0 microns) and granular protoplasm. From the intestine of a cockroach (*Blatta* (*Periplaneta*) *orientalis*).

Bacillus butyricus Hueppe. (Hueppe, Mitteil. kaiserl. Gesundheitsamte, *2*, 1884, 309; not *Bacillus butyricus* Macé, Traité de Bact., 1st ed., 1888; not *Bacillus butyricus* Botkin, Ztschr. f. Hyg., *11*, 1892, 421; *Clostridium hueppei* Trevisan, I generi e le specie delle Batteriacee, 1889, 22; *Bacillus pseudobutyricus* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 207; *Bacillus hueppei* Chester, Man. Determ. Bact., 1901, 276.)

Bacillus calfactor Miehe. (Arb. der deutsch. Landw. Gesel., Berlin, Heft 3, 1905, 76; Die Selbsterhitzung des Heues, Jena, 1907, 49.) Thought to be the most important thermogenic microorganism in the fermentation of hay. From heating hay.

Bacillus canaliculatus Wilhelmy. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 20.) From meat extract.

Bacillus canceris Migula. (Syst. d. Bakt., *2*, 1900, 625.) From a case of stomach cancer.

Bacillus caniperda Migula. (Ovalbacillus der Hundestaupe, Galli-Valerio, Cent. f. Bakt., I Abt., *19*, 1896, 694; Migula, Syst. d. Bakt., *2*, 1900, 764; *Bacterium canis* Chester, Man. Determ. Bact., 1901, 198.) From nasal mucus and urine of dogs.

Bacillus capillaceus Wright. (Mem. Nat. Acad. Sci., *7*, 1895, 456.) From water.

Bacillus capsici Pavarino and Turconi. (Atti Istit. Bot. R. Univ. Pavia, *15*, 1918, 207.) Causes leaf wilt of pepper (*Capsicum annuum*). May be identical with disease caused by *Pseudomonas vesicatoria* (Stapp, in Sorauer, Handbuch der Pflanzen-Krankheiten, *2*, 5 Aufl., 1928, 262).

Bacillus carniphilus Wilhelmy. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 19.) From meat extract.

Bacillus carnosus Zimmermann. (Tils, Bakt. Untersuch. d. Freiburg. Leitungswässer, Leipzig, 1890, No. 57; Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, II Reihe, 1894, 4.) From water.

Bacillus catenulatus Bartels. (Cent. f. Bakt., II Abt., *103*, 1940, 27.) Growth on media containing M/100 phenol. Four strains isolated from soil.

Bacillus cepae Bassalik and Edelstein-Kosowa. (Acta Soc. Bot. Polon., *10*, 1933, 519.) From diseased onions (*Allium cepa*).

Bacillus cerealium Gentner. (Cent. f. Bakt., II Abt., *50*, 1920, 428; *Pseudomonas cerealia* Stapp, in Sorauer, Handbuch der Pflanzen-Krankheiten, *2*, 1928, 22; *Bacterium cerealinum* Elliott, Manual Bacterial Plant Pathogens, 1930, 111.) Pathogenic for barley (*Hordeum vulgare*), rye (*Secale cereale*) and wheat (*Triticum sp.*).

Bacillus cinctus Ravenel. (Mem. Nat. Acad. Sci., *8*, 1896, 30.) From soil.

Bacillus cirroflagellosus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 266.) Central spores. Found in marine mud.

Bacillus cladoi Trevisan. (Bacille pedunculé, Clado, Bull. Soc. Anat. Paris, 1887, 339; Trevisan, I generi e le specie delle Batteriacee, 1889, 14; *Bacillus pendunculatus* (sic) Eisenberg, Bakt. Diag., 3 Aufl., 1891, 340; *Bacillus septicus vesicae* Sternberg, Man. of Bact., 1893, 475.) From urine in a case of cystitis.

Bacillus closteroides Gray and Thornton. (Cent. f. Bakt., II Abt., *73*, 1928, 93.) Decomposes phenol. Probably identical with or a variety of *Bacillus circulans*. Sixteen strains isolated from Rothamsted soils.

Bacillus coccineus Pansini. (Pansini, Arch. f. path. Anat., *122*, 1890, 437; not *Bacillus coccineus* Catiano, in Cohn, Beitr. z. Biol. d. Pflanzen, 7, 1896, 339.) From sputum. Red pigment.

Bacillus colorans Libermann. (Jour. of Microbiol., Ukraine, *5*, 1938, 73; abst. in Cent. f. Bakt., II Abt., *101*, 1940, 81.) From fruit conserves containing 10 to 20 per cent sugar.

Bacillus comesii Rossi. (Ann. d. Scuola d. Agricult. in Portici, 1903; Arch. di Farmacologia sperim., *3*, 1904, fasc. 10.) Similar to *Bacillus mesentericus*. Said to have the ability to dissolve plant particles.

Bacillus concoctans Patrick and Werkman. (Iowa State Coll. Jour. Sci., 7, 1933, 415.) Ferments xylan. One culture isolated from soil.

Bacillus conjunctivitidis subtiliformis Michalski. (Cent. f. Bakt., I Abt., Orig., *36*, 1904, 212.) From more than 50 cases of acute conjunctivitis. Similar to *Bacillus subtilis*.

Bacillus consolidus Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 191.) Good growth on Ca n-butyrate agar. One strain isolated from Cuban soil.

Bacillus contextus Migula. (*Bacillus D*, Peters, Botan. Zeitung, *47*, 1889; Migula, Syst. d. Bakt., *2*, 1900, 522.) From leaven.

Bacillus corrugatus Migula. (*Bacillus mesentericus vulgatus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 322; Bacillus No. II, Flügge, Ztschr. f. Hyg., *17*, 1894, 294; *Bacillus lactis* No. II, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 208; Migula, Syst. d. Bakt., *2*, 1900, 583.) From milk.

Bacillus corruscans Schroeter. (In Cohn, Kryptog. Flora v. Schlesien, *3*, 1, 1886, 158.) From cooked potato.

Bacillus costatus Lloyd. (Jour. Bact., *21*, 1931, 94.) From sea water off Scotland. Nitrates and nitrites reduced to nitrogen.

Bacillus crinatus Chester. (Bacillus No. 5, Pansini, Arch. f. path. Anat., *122*, 1890, 441; Chester, Man. Determ. Bact., 1901, 281.) From sputum.

Bacillus crinitus Wright. (Wright, Mem. Nat. Acad. Sci., 7, 1895, 453; *Bacterium crinatum* (sic) Chester, Man. Determ. Bact., 1901, 192.) From river water.

Bacillus crystalloides Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 371; *Bacterium crystaloides* (sic) Chester, Man. Determ. Bact., 1901, 191.) From the air.

Bacillus cubensis Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 192.) Good growth on Ca n-butyrate agar. Two cultures isolated from soils from Cuba.

Bacillus cystiformis Trevisan. (Bacille cystiforme, Clado, Bull. Soc. Anat. Paris, 1887, 339; Trevisan, I generi e le specie delle Batteriacee, 1889, 14.) From urine in a case of cystitis.

Bacillus cytaseus McBeth and Scales. (U. S. Dept. Agr., Bur. Plant Industry, Bull. 266, 1913, 39; *Bacterium cytaseum* Holland, Jour. Bact., *5*, 1920, 218.) Requires cellulose for best growth. From decomposing materials and soil.

Bacillus cytaseus var. *zonalis* Kellerman et al. (Cent. f. Bakt., II Abt., *39*, 1913, 511.) From soil from Utah. While no spores were observed, this organism was like *Bacillus cytaseus* except that colonies on cellulose agar showed con-

centric opaque or semi-opaque and transparent zones.

Bacillus danteci Kruse. (Bacille rouge de Terre-Neuve, Le Dantec, Ann. Inst. Past., *5*, 1891, 662; Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 270.) From reddened salt cod fish.

Bacillus daucarum von Wahl. (Cent. f. Bakt., II Abt., *16*, 1906, 494.) Apparently a strain of *Bacillus subtilis*. From canned carrots.

Bacillus demmei Trevisan. (Bacillus der Erythema nodosum, Demme, Fortschr. d. Med., *6*, 1888, 257; Trevisan, I generi e le specie delle Batteriacee, 1889, 14; *Bacillus erythematis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 426; *Bacillus erythematis maligni* Kruse, *ibid.*, 479; *Bacterium erythematis* Migula, Syst. d. Bakt., *2*, 1900, 346.) From erythema nodosum (skin).

Bacillus dendroides Holzmüller. (Cent. f. Bakt., II Abt., *23*, 1909, 331.) From frog feces. Closely related to *Bacillus mycoides*.

Bacillus dendroides Thornton. (Thornton, Ann. Appl. Biol., *9*, 1922, 247; not *Bacillus dendroides* Holzmüller, *loc. cit.*) Common in Rothamsted soil. Said to belong to the *Bacillus subtilis* group.

Bacillus dentatus Heigener. (Cent. f. Bakt., II Abt., *93*, 1935, 106.) Good growth on valine agar. Two cultures isolated from soil of Jugoslavia and North Carolina.

Bacillus destruens von Wahl. (Cent. f. Bakt., II Abt., *16*, 1906, 502.) From boiled asparagus.

Bacillus detrudens Wright. (Mem. Nat. Acad. Sci., *7*, 1895, 452.) From water.

Bacillus diastaticus Boyarska. (Izvestia Acad. Sci., U. S. S. R., Biol. Ser., 1941.) Thermophilic.

Bacillus disciformans Zimmermann. (Zimmermann, Bakt. unserer Trink. u. Nutzwässer, Chemnitz, II Reihe, 1894, 48; *Bacterium disciformans* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 238.) From waste water. Apparently not identical with *Bacillus disciformis* Gräfenhan, although the name suggests possible relationship.

Bacillus disciformis Gräfenhan. (Inaug. Diss., Halle, 1891, 1.) From water. From the description, this organism may be *Bacillus subtilis*.

Bacillus distortus (Duclaux) Trevisan. (*Tyrothrix distortus* Duclaux, Ann. Inst. Nat. Agron., *4*, 1882, 23; Trevisan, I generi e le specie delle Batteriacee, 1889, 16.) From milk.

Bacillus dobelli Duboscq and Grassé. (Arch. Zool. Expér. et Gén., *66*, 1927, 487; *Bacillus* (*Flexilis*) *dobelli* Duboscq and Grassé, *ibid.*, 487.) Similar to *Bacillus flexilis* Dobell. Found in rectum of a termite (*Calotermes* (*Glyptotermes*) *iridipennis*). These authors suggest that *Bacillus flexilis* Dobell, *Bacillus butschlii* Schaudinn and *Bacillus dobelli* be grouped under the name *Flexilis*.

Bacillus duclauxii (Miquel) Chester. (*Bacillus ureae* Miquel, Bull. Soc. Chim. d. Paris, *31*, 1879, 391; *Urobacillus duclauxii* sive *Bacillus ureae β* Miquel, Ann. d. Microg., *2*, 1889–1890, 53, 122 and 145; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *10*, 1898, 123.) From water and soil.

Bacillus dysodes Zopf. (Die Spaltpilze, 3 Aufl., 1885, 90.) From fermenting dough.

Bacillus elegans Heigener. (Cent. f. Bakt., II Abt., *93*, 1935, 103.) Four cultures isolated from soil, one from Jugoslavia and three from Germany.

Bacillus emulsionis Beijerinck. (Folia Microbiol., *1*, 1912, 377; see Perquin, Jour. Microbiol. and Serol., *6*, 1940, 226.) Produces slime in sucrose solutions.

Bacillus encephaloides Trevisan. (Bacille de l'air *f*, Babes, in Cornil and Babes, Les Bactéries, 1886, 150; Trevisan, I generi e le specie delle Batteriacee, 1889, 20.) From the air.

Bacillus enterothrix Collin. (Arch. Zool. Expér. et Gén., *51*, 1913, Notes and Revue, No. 3.) Found in the rectum of toad tadpoles (*Alytes sp.*).

Bacillus epidermidis (Bizzozero) Bordoni-Uffreduzzi. (*Leptothrix epidermi-*

dis Bizzozero, Arch. f. path. Anat., *98*, 1884, 441; Bordoni-Uffreduzzi, Fortschr. d. Med., *4*, 1886, 156; Carcinombacillus, Scheurlen, Deutsche med. Wochnschr., 1887, 1083; *Bacillus mesentericus rubiginosus* Senger, Cent. f. Bakt., *3*, 1888, 603; *Bacillus bizzozerianus* Trevisan, I generi e le specie delle Batteriacee, 1889, 14; *Bacillus scheurleni* Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 367.) From the human mouth and skin. Macé (Traité pratique de Bact., 4th ed., 1901, 1071) says that this organism is the ordinary potato bacillus, i.e., *Bacillus vulgatus*.

Bacillus epiphytus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 266.) Central spores. Found associated with marine phytoplankton.

Bacillus erodens Ravenel. (Mem. Nat. Acad. Sci., *8*, 1896, 35.) From soil.

Bacillus esterificans Maassen. (Arb. a. d. kaiserl. Gesundheitsamte, *15*, 1899, 504; *Plectridium esterificans* Huss, Cent. f. Bakt., II Abt., *19*, 1907, 52.) Found in a solution of decomposing litmus; also isolated from butter.

Bacillus evanidus Grohmann. (Morphologisch-biologische Beiträge zur Kenntnis der Wasserstoffbakterien, Inaug. Diss., Univ. Leipzig, 1923; Cent. f. Bakt., II Abt., *61*, 1924, 207; Ruhland and Grohmann, Jahrb. Wissensch. Botanik, *63*, 1924, 321.) Oxidizes hydrogen in the presence of oxygen to form water. Presumably widely distributed in soil.

Bacillus exiguus Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 44.) Isolated 3 times from garden air.

Bacillus exilis Bartels. (Cent. f. Bakt., II Abt., *103*, 1940, 29.) Growth in media containing M/100 phenol. Eight strains isolated from soil.

Bacillus fastidiosus den Dooren de Jong. (Cent. f. Bakt., II Abt., *79*, 1929, 344.) Six strains isolated from unheated garden soil.

Bacillus ferrigenus Bargaglio-Petrucci. (Nuovo Giornale botanico italiano, 1913, 1914, 1915; quoted from De Rossi, Microbiol. Agraria e Technica, 1927, 904.) A facultative thermophile, growing up to 65° to 70°C.

Bacillus festinus McBeth. (Soil Sci., *1*, 1916, 451.) Filter paper decomposed to a grayish-white felt-like mass. From soil in California.

Bacillus filamentosus Klein. (Klein, see Migula, Syst. d. Bakt., *2*, 1900, 285; *Bacterium filamentosum* Burchard, Arb. bakt. Inst. Karlsruhe, *2*, Heft 1, 1902, 22.)

Bacillus filaris Migula. (Bacillus No. XI, Flügge, Ztschr. f. Hyg., *17*, 1894, 296; *Bacillus lactis* No. XI, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 209; Migula, Syst. d. Bakt., *2*, 1900, 579; *Bacillus aromaticus* Chester, Man. Determ. Bact., 1901, 276; not *Bacillus aromaticus* Pammell, Bull. No. 21, Iowa Agr. Exp. Sta., 1893, 792; not *Bacillus aromaticus* Grimm, Cent. f. Bakt., II Abt., *8*, 1902, 584.) From milk.

Bacillus filicolonicus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 270.) Subterminal spores. From sea water and marine mud.

Bacillus filiformis (Duclaux) Trevisan. (*Tyrothrix filiformis* Duclaux, Ann. Inst. Nat. Agron., *4*, 1882, 23; Trevisan, I generi e le specie delle Batteriacee, 1889, 16; not *Bacillus filiformis* Tils, Ztschr. f. Hyg., *9*, 1890, 317; not *Bacillus filiformis* Migula, Syst. d. Bakt., *2*, 1900, 587.) From cheese.

Bacillus fissuratus Ravenel. (Mem. Nat. Acad. Sci., *8*, 1896, 38.) From soil.

Bacillus fitzianus Zopf. (Fitz, Ber. d. deutsch. chem. Gesellsch., *6*, 1873, 48; *ibid.*, *9*, 1876, 1348; *ibid.*, *10*, 1877, 276; Glycerinaethylbacterie, Buchner, in Nägeli, Untersuch. ü. niedere Pilze, 1882, 220; Zopf, Die Spaltpilze, 1 Aufl., 1883, 52; *Bacterium fitzianum* Zopf, Die Spaltpilze, 2 Aufl., 1884, 49.) From boiled hay infusions. Forms butyric acid.

Bacillus flagellifer Migula. (Bacillus No. VI, Flügge, Ztschr. f. Hyg., *17*, 1894, 294; *Bacillus lactis* No. VI, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 209; Migula, Syst. d. Bakt.,

2, 1900, 581; *Bacillus rudis* Chester, Man. Determ. Bact., 1901, 279.) From milk.

Bacillus flavescens Weiss. (Weiss, Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 258; not *Bacillus flavescens* Pohl, Cent. f. Bakt., *11*, 1892, 144.) From brewer's grains. Uncommon.

Bacillus flavidus Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 185; not *Bacillus flavidus* Fawcett, Rev. Indust. y Agrico. de Tucuman, *13*, 1922, 5; not *Bacillus flavidus* Morse, Jour. Inf. Dis., *11*, 1912, 284.) Good growth on Ca n-butyrate agar. One culture isolated from soil from Egypt.

Bacillus flavidus alvei Klamann. (Bienenwirtschaftl. Cent., Hanover, 1890, No. 2.) Associated with foulbrood of bees.

Bacillus flavoviridis Migula. (Maschek, Bakt. Untersuch. d. Leitmeritzer Trinkwässer, Leitmeritz, 1887; Migula, Syst. d. Bakt., *2*, 1900, 821.) From water.

Bacillus flexilis Dobell. (Quart. Jour. Microsc. Sci., *52*, 1908, 121; Arch. f. Protistenk., *26*, 1912, 117.) Reported as being similar to *Bacillus bütschlii* Schaudinn although only half its size. From the large intestine of frogs (*Rana temporaria*) and toads (*Bufo vulgaris*).

Bacillus flexus Batchelor. (Jour. Bact., *4*, 1919, 23.) Resembles *Bacillus megatherium*. From intestinal contents of a child.

Bacillus fluorescens undulatus Ravenel. (Mem. Nat. Acad. Sci., *8*, 1896, 20.) From soil.

Bacillus foliaceus Migula. (*Bacillus mesentericus fuscus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 321; Bacillus No. IV, Flügge, Ztschr. f. Hyg., *17*, 1894, 294; *Bacillus lactis* No. IV, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 208; Migula, Syst. d. Bakt., *2*, 1900, 582.) From milk, air and soil.

Bacillus formosus Heigener. (Cent. f. Bakt., II Abt., *93*, 1935, 101; not *Bacillus formosus* Ravenel, Mem. Nat. Acad. Sci., *8*, 1896, 12.) One culture isolated from soil from Montenegro.

Bacillus foutini Chester. (Bacillus D, Foutin, Cent. f. Bakt., *7*, 1890, 373; Chester, Man. Determ. Bact., 1901, 285.) From hail.

Bacillus frankei (sic) DeToni and Trevisan. (Sarkombacillen, Francke, Münch. med. Wochnschr., 1888, No. 4; abst. in Cent. f. Bakt., *3*, 1888, 601; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 967.) From cases of sarcoma.

Bacillus freudenreichii (Miquel) Chester. (*Urobacillus freudenreichii* sive *Bacillus ureae* γ Miquel, Ann. d. Micrographie, *2*, 1890, 367 and 488; Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *10*, 1898, 110.) Löhnis (Cent. f. Bakt., II Abt., *14*, 1905, 719) considered this a variety of *Bacillus pumilus*. Gibson (Jour. Bact., *29*, 1935, 493) believed it belonged to the *Bacillus pasteurii* group although no authentic cultures were available. From soil.

Bacillus frutodestruens Madhok and Ud-Din. (Indian Jour. Agr. Sci., *13*, 1943, 129.) Causes a rot of tomato fruit.

Bacillus funicularis Kluyver and Van Niel. (Planta, Arch. f. wissensch. Botanik, *2*, 1926, 507.) Exhibits contact irritability. From soil.

Bacillus furvus Goadby. (Dental Cosmos, *42*, 1900, 322.) From the mouth. Associated with dental caries.

Bacillus (*Streptobacter*) *fusisporus* Schroeter. (In Cohn, Krypt. Flora v. Schlesien, *3*, 1, 1886, 161.) From waste water in a sugar factory.

Bacillus fusus Batchelor. (Jour. Bact., *4*, 1919, 27.) Said to resemble *Bacillus centrosporus*, i.e., *Bacillus brevis*. From feces.

Bacillus gangliformis Ravenel. (Ravenel, Mem. Nat. Acad. Sci., *8*, 1896, 34; *Bacterium gangliforme* Chester, Man. Determ. Bact., 1901, 193.) From soil.

Bacillus gangraenae Chester. (*Bacillus gangraenae pulpae* Arkövy, Cent. f. Bakt., *23*, 1897, 921; Chester, Man. Determ. Bact., 1901, 275; not *Bacillus gangraenae* Tilanus, Nederl. Tijdschr. v.

Geneeskunde, *21*, 1885, 110.) Associated with gangrene of tooth pulp and caries of teeth.

Bacillus gasoformans Pammel. (Pammel, Cent. f. Bakt., II Abt., *2*, 1896, 642; not *Bacillus gasoformans* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 107; *Bacillus pammelii* Chester, Man. Determ. Bact., 1901, 270.) From cheese.

Bacillus gelatinosus Migula. (*Bacterium gelatinosum betae* Glaser, Cent. f. Bakt., II Abt., *1*, 1895, 879; Migula, Syst. d. Bakt., *2*, 1900, 805.) Produces slime in sucrose solutions. Probably a variety of *Bacillus vulgatus* according to Sacchetti (Cent. f. Bakt., II Abt., *95*, 1936, 115).

Bacillus geniculatus (Duclaux) Trevisan. (*Tyrothrix geniculatus* Duclaux, Ann. Inst. Nat. Agron., *4*, 1882, 23; Trevisan, I generi e le specie delle Batteriacee, 1889, 16; not *Bacillus geniculatus* De Bary, Inaug. Diss., Strassburg, Leipzig, 1885; not *Bacillus geniculatus* Wright, Mem. Nat. Acad. Sci., *7*, 1894, 459; *Bacillus gonatodes* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 964; *Bacterium geniculatum* Migula, Syst. d. Bakt., *2*, 1900, 322.) From milk.

Bacillus gigas (Koch) Trevisan. (*Streptobacteria gigas-pericardii* Billroth, Die Vegetationsformen von Coccobacteria septica, Berlin, 1874, 60; *Streptobacteria gigas* Koch, in Cohn, Beitr. z. Biol. d. Pflanz., *2*, Heft 3, 1877, 429; *Metallacter gigas* Trevisan, Batter. ital., 1879, 25; Trevisan, Atti. d. Accad. Fis.-Med.-Stat., Milan, Ser. 4, *3*, 1886, 96; not *Bacillis gigas* van der Goot, Med. Proefstation voor de Java Suikerindust., pt. 5, No. 10, 1915, 284; not *Bacillus gigas* Zeissler and Rassefeld, Arch. f. wiss. u. prakt. Tierheilk., *59*, 1929, 419.) From pericardial exudate.

Bacillus ginglymus Ravenel. (Mem. Nat. Acad. Sci., 8, 1896, 37.) From soil.

Bacillus glaciformis Wilhelmy. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 29.) From meat extract.

Bacillus globifer Bartels. (Cent. f. Bakt., II Abt., *103*, 1940, 26.) Growth on media containing M/100 phenol. Author considers it similar to *Bacillus alvei*. Five strains isolated from soil.

Bacillus glutinis Patrick and Werkman. (Iowa State Coll. Jour. Sci., *7*, 1933, 414.) Ferments xylan. Two strains isolated from decayed apple wood.

Bacillus glycinophilus Rippel. (Rippel, Arch. f. Mikrobiol., *8*, 1937, 42; also see Rippel and Nabel, *ibid.*, *10*, 1938, 359.) From intestines of cattle. Fresh cultures on agar form protein from glycine and glucose.

Bacillus gossypina Stedman. (Alabama Agr. Exp. Sta. Bul. 55, 1894, 6; Earle, Alabama Agr. Exp. Sta. Bul. 107, 1899, 311.) Reported as cause of boll rot on cotton (*Gossypium sp.*)

Bacillus granularis Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 180.) Very good growth on Ca n-butyrate agar. One culture isolated from garden soil in Germany.

Bacillus granulosus Russell. (Russell, Ztschr. f. Hyg., *11*, 1892, 194; *Bacterium granulosum* Chester, Man. Determ. Bact., 1901, 194.) From mud from the Gulf of Naples.

Bacillus grossus Migula. (Bacterienart No. 13, Lembke, Arch. f. Hyg., *26*, 1896, 308; Migula, Syst. d. Bakt., *2*, 1900, 570.) From the intestines of infants.

Bacillus gryllotalpae Metalnikov and Meng. (Compt. rend. Acad. Sci., Paris, *201*, 1935, 367.) From diseased larvae of the cricket (*Gryllotalpa gryllotalpa*).

Bacillus guano Stapp. (Cent. f. Bakt., II Abt., *51*, 1920, 29.) From soil previously fertilized with guano.

Bacillus gummosus Happ. (Bakt. und Chem. Untersuch. über die schleimige Gahrung. Univ. Basel, 1893, 34; abst. in Cent. f. Bakt., *14*, 1893, 175.) From digitalis infusions. Presumably a mucoid form of a common spore-former. See *Bacterium gummosum* Ritsert.

Bacillus harai Hori and Miyake. (Rpt. Imp. Agr. Exp. Sta. Nishigahara, *38*,

1911, 69.) Pathogenic for willow (*Salix sp.*).

Bacillus hessii (Guillebeau) Kruse. (*Bacterium hessii* Guillebeau, Landw. Jahrb. d. Schweiz, *5*, 1891, 138; Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 210.) There is some question whether the original culture was a spore-former or whether it was mixed with one of the common slimy milk organisms. From slimy milk.

Bacillus hirudinis Schweizer. (Arch. f. Mikrobiol., *7*, 1936, 235.) From the digestive slime of leeches (*Hirudo medicinalis* and *Hirudo officinalis*).

Bacillus hollandicus Stapp. (Cent. f. Bakt., II Abt., *51*, 1920, 47.) From soil from Delft.

Bacillus hoplosternus Paillot. (Compt. rend. Acad. Sci., Paris, *163*, 1916, 774; Ann. Inst. Past., *33*, 1919, 403.) Isolated once from the body fluid of a June bug. Pathogenic for several species of insects.

Bacillus imminutus McBeth. (Soil Sci., *1*, 1916, 455.) Growth only in the presence of cellulose. From ten different soils of California.

Bacillus immobilis Steinhaus. (Jour. Bact., *42*, 1941, 783.) The author states that it probably belongs to the *Bacillus adhaerens* group. From rectum of larvae of the sphinx moth (*Ceratomia catalpae*).

Bacillus imomarinus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 265.) Subterminal spores. From marine bottom deposits in shoal waters.

Bacillus indifferens Soriano. (Thesis, Univ. Buenos Aires, 1935, 565.) One strain isolated from soil.

Bacillus infantilis Kendall. (Jour. Biol. Chem., *5*, 1909, 419 and 439.) From the intestine in cases of infantilism. Saprophytic.

Bacillus intermittens Wilhelmy. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 23.) From meat extract.

Bacillus intrapallans Forbes. (Bull. Illinois State Lab. Natur. Hist., Art. IV, 1886, 283, 288 and 297.)

Bacillus jubatus Bartels. (Cent. f. Bakt., II Abt., *103*, 1940, 24.) Very good growth on media containing M/50 phenol. Nine strains isolated from soil.

Bacillus kaleidoscopicus Wilhelmy. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 31.) From meat extract.

Bacillus kefir Kuntze. (Cent. f. Bakt., II Abt., *24*, 1909, 116.) From kefir, a Caucasian milk beverage.

Bacillus kermesinus Migula. (Karminroter Bacillus, Tataroff, Inaug. Diss., Dorpat, 1891, 67; Migula, Syst. d. Bakt., *2*, 1900, 858.) From water.

Bacillus kildini Issatchenko. (Recherches sur les Microbes de l'Océan Glacial Arctique. Petrograd, 1914.) From sea water.

Bacillus koubassoffii Chester. (Bacillus der krebsartigen Neubildungen, Koubassoff, Vortrag. Moskauer Militärärztlichen Verein, 1888, No. 22; abst. in Cent. f. Bakt., *7*, 1890, 317; Chester, Man. Determ. Bact., 1901, 282.) From cancerous growths of the human stomach.

Bacillus lacca Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 411.) From the stomachs and intestines of birds.

Bacillus lactis-albus Chester. (*Bacillus lactis albus* Sternberg, Man. of Bact., 1893, 680; Chester, Man. Determ. Bact., 1901, 277.) From milk.

Bacillus lactucae Voglino. (Ann. R. Accad. Agr. Torino, *46*, 1903, 25.) Pathogenic for lettuce (*Lactuca sativa*).

Bacillus lasiocampa Brown. (Amer. Museum Novitates, No. 251, 1927, 7.) Said to belong to *Bacillus subtilis* group. From ovaries and egg tubes of tent caterpillar moth.

Bacillus latvianus Kalnins. (Latvijas Univ. Raksti, Serÿa I, No. 11, 1930, 265.) Cellulose attacked at 34°C but not at 37°C. Probably from soil.

Bacillus lautus Batchelor. (Jour. Bact., *4*, 1919, 30.) One culture from feces.

Bacillus legrosii Hauduroy et al. (Legros, Thèse Méd. Paris, 1902; Hauduroy et al., Dict. d. Bact. Path., 1937, 43.)

Facultative anaerobe producing gaseous gangrene. From a gaseous suppuration.

Bacillus leguminiperdus von Oven. (Cent. f. Bakt., II Abt., *16*, 1906, 67; *Bacterium leguminiperdum* Stevens, The Fungi which Cause Plant Disease, 1913, 28.) Pathogenic for lupine (*Lupinus sp.*), kidney bean (*Phaseolus vulgaris*), pea (*Pisum sativum*), tomato (*Lycopersicum esculentum*).

Bacillus lehmanni Herter. (Microbe 5A, Choukévitch, Ann. Inst. Past., *25*, 1911, 350; Herter, Just's Botan. Jahresber., *39*, 2 Abt., Heft 4, 1915, 748.) From the large intestine of the horse.

Bacillus lekitosis Perlman. (N. Y. State Dept. Agr. and Markets, Ann. Rept., 1931, 115.) Egg lecithin hydrolyzed completely by powerful extracellular enzyme. From contaminated sample of whole mixed eggs.

Bacillus lesagei Trevisan. (Bacille de la diarrhée verte des enfants, Lesage, Bull. Acad. Méd. Paris, Oct. 25, 1887; Trevisan, I generi e le specie delle Batteriacee, 1889, 14.) From the intestine of infants.

Bacillus levaniformans Greig Smith. (Proc. Linn. Soc. New South Wales, *26*, 1901, 589, 674 and 684; Cent. f. Bakt., II Abt., *8*, 1902, 596.) Produces slime in sucrose solutions. Probably a variety of *Bacillus vulgatus* according to Sacchetti (Cent. f. Bakt., II Abt., *95*, 1936, 115).

Bacillus licheniformis (Weigmann) Chester. (Bacterie a, Weigmann, Cent. f. Bakt., II Abt., *2*, 1896, 155; *Clostridium licheniforme* Weigmann, *loc. cit.*, *4*, 1898, 822; Chester, Man. Determ. Bact., 1901, 287; see also Gibson, Soc. Agric. Bact. (British); Abstr. Proc., 1927, Paper No. 10; Gibson and Topping, *ibid.*, 1938, 43; Gibson, *ibid.*, 1943, 13.) Gibson places this with *Bacillus subtilis* although it was originally described as being Gram-negative and forming clostridial sporangia. Spore germination polar.

Bacillus lichenoides Grohmann. (Morphologisch-biologische Beiträge zur Kenntnis der Wasserstoffbakterien, Inaug. Diss., Univ. Leipzig, 1923; Cent. f. Bakt., II Abt., *61*, 1924, 267; Ruhland and Grohmann, Jahrb. wissensch. Botanik, *63*, 1924, 321.) Oxidizes hydrogen in the presence of oxygen to form water. Presumably widely distributed in soil.

Bacillus lignivorans Patrick and Werkman. (Iowa State Coll. Jour. Sci., *7*, 1933, 410.) Ferments xylan. One culture isolated from decayed maple wood.

Bacillus lignorum Patrick and Werkman. (Iowa State Coll. Jour. Sci., *7*, 1933, 410.) Ferments xylan. One culture isolated from decayed apple wood.

Bacillus limnophilus Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 190.) Good growth on Ca n-butyrate agar. One culture isolated from soil of Germany.

Bacillus lingardi Trevisan. (Bacillus de la stomatite ulcereuse du veau, Lingard and Batt; Trevisan, I generi e le specie delle Batteriacee, 1889, 14.) From ulcerations on the tongue and mucous membrane of the mouth of calves.

Bacillus lividus Zimmermann. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, II Reihe, 1894, 18; not *Bacillus lividus* Voges, Cent. f. Bakt., *14*, 1893, 303.) From water.

Bacillus longior Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 57.) Isolated once from garden air.

Bacillus longus Migula. (Bacillus No. VII, Flügge, Ztschr. f. Hyg., *17*, 1894, 296; *Bacillus lactis* No. VII, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 209; Migula, Syst. d. Bakt., *2*, 1900, 581; not *Bacillus longus* Chester, Man. Determ. Bact., 1901, 303; *Bacillus plicatus* Chester, *ibid.*, 275; not *Bacillus plicatus* Frankland and Frankland, Philos. Trans. Royal Soc. London, *178*, B, 1887, 273; not *Bacillus plicatus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, I Reihe, 1890, 54; not *Bacillus plicatus* Deetjen, Inaug. Diss., Würzburg, 1890; not *Bacillus plicatus* Copeland, Rept. Filtration Commission, Pittsburgh, 1899, 348.) From milk.

Bacillus loxosporus Burchard. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 1, 1902, 49.) From the air. Synonym of *Bacillus simplex* according to Gottheil, Cent. f. Bakt., II Abt., *7*, 1901, 633.

Bacillus luteus Garbowski. (*Bacillus luteus sporogenes* Smith and Baker, Cent. f. Bakt., II Abt., *4*, 1898, 788; Garbowski, Cent. f. Bakt., II Abt., *19*, 1907, 641.) From two samples of beet sugar.

Bacillus lutzae Brown. (Amer. Museum Novitates, No. 251, 1927, 8.) Pathogenic for certain flies. Dying individuals of the green blow fly (*Lucilia sericata*) yielded pure cultures.

Bacillus maculatus Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 184.) Good growth on Ca n-butyrate agar. Two cultures isolated from soils from Cuba and Germany.

Bacillus maïdis Paltauf and Heider. (Paltauf and Heider, Wiener med. Jahrb., *3*, 1888, 383; Paltauf, Med. Jahrb., No. 8, 1889.) From an infusion of maize; also from feces in cases of pellagra. This species was originally described by Cuboni, probably in the Rendic. R. Accad. dei Lincei, *1*, 1886. It was later shown to be a spore-former of the *Bacillus mesentericus* group. It was quite different from the organism isolated by Tataroff (*Pseudomonas maidis* Migula) and identified by him as *Bacillus maidis*.

Bacillus malakofaciens von Wahl. (Cent. f. Bakt., II Abt., *16*, 1906, 499.) Reported to be similar in morphology and physiology to *Bacillus asterosporus*. From preserved asparagus and from green beans.

Bacillus maritimus Russell. (Russell, Bot. Gazette, *18*, 1893, 445; *Bacterium maritimum* Chester, Man. Determ. Bact., 1901, 189.) From sea-mud.

Bacillus mazun Weigmann, Gruber and Huss. (Cent. f. Bakt., II Abt., *19*, 1907, 72.) From the Armenian milk product, mazun.

Bacillus mediosporus Migula. (Bacillus No. VIII, Flügge, Ztschr. f. Hyg., *17*, 1894, 296; *Bacillus lactis* No. VIII, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 209; Migula, Syst. d. Bakt., *2*, 1900, 580; *Bacillus magnus* Chester, Man. Determ. Bact., 1901, 276.) From milk.

Bacillus medio-tumescens Saito. (Jour. Coll. Sci. Imp. Univ., Tokyo, *23*, Art. 15, 1908, 45.) Isolated twice from garden air.

Bacillus megatherium Ravenel. (Ravenel, Mem. Nat. Acad. Sci., *8*, 1896, 11; not *Bacillus megatherium* De Bary, Vergleich. Morph. u. Biol. d. Pilze, 1884, 499; *Bacillus megatherium* var. *ravenelii* Chester, Man. Determ. Bact., 1901, 271.) From soil.

Bacillus melanosporus Schroeter. (Eine *Bacillus* Art, Eidam, Beitr. z. Biol. d. Pflanz., *1*, 3, 1875, 216; Schroeter, in Cohn, Kryptog. Flora v. Schlesien, *3*, 1, 1886, 159.) From cooked potato.

Bacillus melonis Patrick and Werkman. (Iowa State Coll. Jour. Sci., *7*, 1933, 411; not *Bacillus melonis* Giddings, Vermont Agr. Exp. Station Bull. 148, 1910, 413.) Ferments xylan. One culture isolated from decayed watermelon.

Bacillus mesentericus fuscus consistens Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 373.) Found as a contamination in a milk culture.

Bacillus mesentericus fuscus granulatus Dyar. (Ann. N. Y. Acad. Sci., *8*, 1895, 373.) Found abundantly in a jar of sterilized milk.

Bacillus mesentericus roseus Zimmermann. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *2*, 1894, 26.) From water. Zimmermann received this culture from Kràl under the above name. Kràl (Sammlung v. Mikroorganismen, Prague, 1900, 7) lists it as a synonym of *Bacillus mesentericus ruber* Globig.

Bacillus mesentericus vulgatus mucosus Ivanovics. (Cent. f. Bakt., I Abt., Orig., *142*, 1938, 52.) Author believed it to be identical or near to *Bacillus vulgatus*

but produces much slime. From drainage water.

Bacillus mesenterioides Deetjen. (Inaug. Diss., Würzburg, 1890.) From sausage.

Bacillus micans Wilhelmy. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 30.) From meat extract.

Bacillus milii (sic) Howard. (Gleanings in Bee Culture, *28*, 1900, 124.) From black brood of the honey bee (*Apis mellifera*).

Bacillus mitochrondrialis Alexeieff. (Arch. f. Protist., *49*, 1924, 399.) From horse manure.

Bacillus modestus Schieblich. (Cent. f. Bakt., I Abt., Orig., *124*, 1932, 269.) Prefers carbohydrate media and 37°C. From grass and meadow plants.

Bacillus monachae (von Tubeuf) Eckstein. (Bacillus B, Hofmann, Die Schlaffsucht (Flacherie) der Nonne (*Liparis monacha*), 1891, Frankfort am Main; *Bacterium monachae* von Tubeuf, Forstl. naturwissensch. Ztschr., *1*, 1892, 34, 277; Eckstein, Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 6.) From diseased caterpillars of the nun moth (*Lymantria monacha*).

Bacillus montanus Werner. (Cent. f. Bakt., II Abt., *87*, 1933, 458.) Good growth on Ca n-butyrate agar. One culture isolated from soil of Germany.

Bacillus moulei DeToni and Trevisan. (Bacille des viandes à odeur de beurre rance des halles de Paris, Nocard and Moulé, Recueil de médecine vétér., Sér. 7, *6*, 18—, 67; DeToni and Trevisan, in Sacardo, Sylloge Fungorum, *8*, 1889, 971.) From spoiled meat.

Bacillus mucilaginosus Migula. (Happ, Inaug. Diss., Berlin, 1893, 28; Migula, Syst. d. Bakt., *2*, 1900, 696.) From a slimy fermentation.

Bacillus mucosus Zimmerman. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, II Reihe, 1894, 8; *Bacterium mucosum* Migula, Syst. d. Bakt., *2*, 1900, 315.) From water.

Bacillus mucronatus Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 58.) Isolated twice from garden air.

Bacillus multipediculus flavus Zimmermann. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, II Reihe, 1894, 42.) From water.

Bacillus muralis Tomaschek. (Botan. Zeit., *46*, 1887, 665.)

Bacillus mutabilis Soriano. (Estudio sistematico de algunas bacterias esporuladas aerobias, Thesis, Univ. Buenos Aires, 1935, 570.) Four strains isolated from fecal matter and Argentine soils.

Bacillus myxodens Burchard. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 1, 1898, 41.) From beer yeast.

Bacillus nebulosus Goresline. (Goresline, Jour. Bact., *27*, 1934, 72; not *Bacillus nebulosus* Wright, Mem. Nat. Acad. Sci., 7, 1894, 465; not *Bacillus nebulosus* Halle, Thèse de Paris, 1898; not *Bacillus nebulosus* Vincent, Ann. Inst. Past., *21*, 1907, 69; not *Bacillus nebulosus gazogenes* Jacobson, Ann. Inst. Past., *22*, 1908, 300.) From a trickling filter receiving creamery wastes.

Bacillus neumanni Herter. (Microbe 5B, Choukévitch, Ann. Inst. Past., *25*, 1911, 350; Herter, Just's Botan. Jahresber., *39*, 2 Abt., Heft 4, 1915, 748.) From the large intestine of the horse.

Bacillus nigrescens Bartels. (Cent. f. Bakt., II Abt., *103*, 1940, 22.) Good growth on media containing M/25 phenol. Three strains isolated from soil.

Bacillus nigricans Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 428.) From the stomach of a bird.

Bacillus nitidis Heigener. (Cent. f. Bakt., II Abt., *93*, 1935, 99.) One culture isolated from soil from Washington, D. C.

Bacillus nitri Ambrož. (Cent. f. Bakt., I Abt., Orig., *51*, 1909, 193.) Used for cytological studies because of its large size. Found on gelatin plates poured for the isolation of yeasts.

Bacillus nitroxus Beijerinck. (Cent. f. Bakt., II Abt., *25*, 1909, 45.) In the absence of air forms N gas, CO_2, and N_2O in nitrate broth. Under aerobic condi-

tions only a weak reduction. From garden soil.

Bacillus nobilis Adametz. (See Freudenreich, Cent. f. Bakt., II Abt., *7*, 1901, 857; *ibid.*, *8*, 1902, 674.) This organism was sold under the name Tyrogen; it was said to play a part in the ripening of hard cheese. This was doubted by Freudenreich who identified it as one of the *Tyrothrix* group. Original description apparently in Osterreichen Mokerei-Zeitung, Nov. 15, 1900; Dec. 1 and 15, 1900; Milchzeitung, No. 48, 1900.

Bacillus novus (Huss) Bergey et al. (*Plectridium novum* Huss, Cent. f. Bakt., II Abt., *19*, 1907, 256; Bergey et al., Manual, 1st ed., 1923, 304.) From sterilized milk.

Bacillus oblongus Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 16.) From the larvae of a moth (*Hyponomeuta evonymella*).

Bacillus oehensis Bartels. (Cent. f. Bakt., II Abt., *103*, 1940, 28.) Growth on media containing M/100 phenol. One culture isolated from soil.

Bacillus oleae Schiff-Giorgini. (Cent. f. Bakt., II Abt., *15*, 1905, 203.) Thought to be the cause of tubercles on the olive tree from which it was isolated.

Bacillus omelianskii Serbinoff. (Zhurnal Bolezni Rastenii, Leningrad, *9*, 1915, 105.) Causes a rot of sorghum.

Bacillus ontarioni (Chorine) Steinhaus. (*Bacterium ontarioni* Chorine, Internat. Corn Borer Invest., Sci. Rpts., *2*, 1929, 44; also Ann. Inst. Past., *43*, 1929, 1658; *B. ontarioni* Paillot, *B.* presumably indicates *Bacterium*, see index, p. 522, L'infection chez les insectes, 1933, 134; Steinhaus, Bacteria Associated Extracellularly with Insects, Minneapolis, 1942, 72.) From diseased larvae of the corn borer (*Pyraustra nubilalis* Hb.).

Bacillus oogenes Migula. (*Bacillus oogenes hydrosulfureus α*, Zörkendörfer, Arch. f. Hyg., *16*, 1893, 385; Migula, Syst. d. Bakt., *2*, 1900, 573.) From hens' eggs.

Bacillus opacus Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 214.) From bean infusions and fermenting cabbage.

Bacillus orae Werner. (Cent. f. Bakt., II Abt., *87*, 1933, 464.) Weak growth on agar containing calcium salts of formic, acetic, and butyric acids. One culture isolated from European soil.

Bacillus oxylacticus Dyar. (Dyar, Ann. N. Y. Acad. Sci., *8*, 1895, 369; *Bacterium oxylacticus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 107.) From air and a culture from Kràl's laboratory labeled *Bacillus oxylacticus*. The latter is given in the Kràl 1900 catalogue as *Bacillus oxalaticus* Zopf and undoubtedly was the organism received by Migula from Zopf and studied by him (Migula, Arb. tech. Hochschule Karlsruhe, *1*, Heft 1, 1894, 139 and Migula, Syst. d. Bakt., *2*, 1900, 538). This is now regarded as having been *Bacillus megatherium* De Bary.

Bacillus pabuli Schieblich. (Cent. f. Bakt., II Abt., *58*, 1923, 204.) Commonly isolated from green and fermenting fodder.

Bacillus pallidus Heigener. (Cent. f. Bakt., II Abt., *93*, 1935, 98.) One strain isolated from soil from New York State.

Bacillus palustris Sickles and Shaw. (Jour. Bact., *28*, 1934, 418; *Rhodobacillus palustris* Sickles and Shaw, Jour. Bact., *38*, 1939, 241.) Decomposes the specific carbohydrate of pneumococcus type III. From swamp and other uncultivated soils.

Bacillus palustris var. *gelaticus* Sickles and Shaw (*loc. cit.*, 419). A variety that decomposes agar slightly. Found only once.

Bacillus paucicutis Burchard. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 1, 1902, 27.) From rye bread.

Bacillus pectocutis Burchard. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 1, 1902, 24.) From the air.

Bacillus pelagicus Russell. (Bot. Gaz., *18*, 1893, 383.) From sea water and marine mud from Woods Hole, Massachusetts.

Bacillus pellucidus Soriano. (Revista

del Instit. Bacteriol., Buenos Aires, *6*, 1935, 567.) Author says colonies resemble *Bacillus simplex*. Habitat probably in soil.

Bacillus peptogenes (Buchanan and Hammer) Bergey et al. (*Bacterium peptogenes* Buchanan and Hammer, Iowa Agr. Exp. Sta. Res. Bull. 22, 1915, 273; Bergey et al., Manual, 1st ed., 1923, 293.) From a tube of litmus milk after autoclaving.

Bacillus peptonans Chester. (*Bacillus lactis peptonans* Sterling, Cent. f. Bakt., II Abt., *1*, 1895, 473; Chester, Man. Determ Bact., 1901, 271.) From milk. Very similar to *Bacillus mesentericus vulgatus* Flügge.

Bacillus peptonificans Lubenau. (Cent. f. Bakt., I Abt., Orig., *40*, 1906, 435.) Similar to *Bacillus subtilis*. Believed to be the cause of an epidemic of gastroenteritis.

Bacillus perlucidulus Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 43.) Isolated 3 times from garden air.

Bacillus petiolatus Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 48.) Isolated twice from garden air.

Bacillus phaseoli von Wahl. (Cent. f. Bakt., II Abt., *16*, 1906, 500.) From canned beans.

Bacillus phenolphilos Bartels. (Cent. f. Bakt., II Abt., *103*, 1940, 21.) Good growth on media containing M/50 phenol. One culture isolated from soil.

Bacillus picrogenes Patrick and Werkman. (Iowa State Coll. Jour. Sci., *7*, 1933, 410.) Ferments xylan. One culture isolated from decayed watermelon.

Bacillus piliformis Tyzzer. (Jour. Med. Research, *37*, 1917, 307.) All attempts to cultivate the organism failed except when mixed with a streptotoccus. Considered aerobic by Ford (Textbook of Bact., 1927, 712). Causes fatal disease of Japanese waltzing mice.

Bacillus piscicidus Migula. (*Bacillus piscicidus agilis* Siebert, Gazeta lekarska, 1895, No. 13–17; abst. in Cent. f. Bakt., *17*, 1895, 888; *Bacterium piscicidus agilis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 140; Migula, Syst. d. Bakt., *2*, 1900, 652; *Bacillus piscicidus nobilis* (sic) Babes and Riegler, Cent. f. Bakt., II Abt., Orig., *33*, 1902–03, 440.) Cause of a fish epidemic in St. Petersburg.

Bacillus pisi von Wahl. (Cent. f. Bakt., II Abt., *16*, 1906, 502.) From young peas.

Bacillus platychoma Gray and Thornton. (Cent. f. Bakt., II Abt., *73*, 1928, 93.) Phenol is attacked. Three strains isolated from soil.

Bacillus plexiformis Goadby. (Dental Cosmos, *42*, 1900, 322.) From the mouth.

Bacillus plicatus Deetjen. (Deetjen, Inaug. Diss., Würzburg, 1890; not *Bacillus plicatus* Frankland and Frankland, Philos. Trans. Royal Soc. London, *178*, B, 1887, 273; not *Bacillus plicatus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, Chemnitz, I Reihe, 1890, 54; not *Bacillus plicatus* Copeland, Rept. Filtration Commission, Pittsburgh, 1899, 348; not *Bacillus plicatus* Chester, Man. Determ. Bact., 1901, 275.) From sausage.

Bacillus pollacii Pavarino. (Atti R. Accad. Naz. Lincei Rend. Cl. Sci. Fis. Math. e Nat., *20*, 1911, 233.) Reported to cause depressed spots on leaves of *Odontoglossum citrosmum*.

Bacillus populi Brisi. (Atti Cong. Nat. Ital. Pom. della Soc. Ital. di Sci. Nat. Milano, 1907, 376.) Reported as cause of galls on branches of poplar trees (*Populus sp.*).

Bacillus pseudanthracis Kruse. (Milzbrandähnlicher Bacillus, Burri, Hyg. Rundschau, *4*, 1894, 339; abst. in Cent. f. Bakt., *16*, 1894, 374; Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 233; not *Bacillus pseudanthracis* Wahrlich, Bakteriol. Studien, Petersburg, 1890–91, 26; *Bacillus pseudo-anthracis* Chester, Man. Determ. Bact., 1901, 280.) From South American bran.

Bacillus pseudococcus Migula. (Bacil-

lus No. 11, Pansini, Arch. f. path. Anat., *122*, 1890, 446; Migula, Syst. d. Bakt., *2*, 1900, 557.) From sputum.

Bacillus pseudodiphthericum magnus Ødegaard. (Acta Path. et Microbiol. Scand., *21*, 1944, 451; see Endicott, Biol. Abst., *20*, 1946, 12926.) From the nose of a child suspected of having diphtheria. Resembles *Corynebacterium diphtheriae* in young cultures. Non-pathogenic.

Bacillus pseudofusiformis Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 47.) Isolated once from garden air.

Bacillus pseudosubtilis Migula. (*Bacillus subtilis similis* Sternberg, Manual of Bact., 1893, 679; Migula, Syst. d. Bakt., *2*, 1900, 618.) From the liver of a yellow fever cadaver.

Bacillus punctiformis Chester. (Bacillus No. 23, Conn, Storrs Agr. Exp. Sta. Rept., 1893, 53; Chester, Man. Determ. Bact., 1901, 284.) From milk.

Bacillus pycnoticus Grohmann. (Cent. f. Bakt., II Abt., *61*, 1924, 261; Ruhland and Grohmann, Jahrb. wissensch. Botanik, *63*, 1924, 321; *Hydrogenomonas pycnotica* Bergey et al., Manual, 3rd ed., 1930, 34.) Oxidizes hydrogen in the presence of oxygen to form water. Presumably widely distributed in soil.

Bacillus quercifolius Deetjen. (Deetjen, Inaug. Diss., Würzburg, 1890; *Bacterium quercifolium* Migula, Syst. d. Bakt., *2*, 1900, 309.) From sausage.

Bacillus rarerepertus Schieblich. (Cent. f. Bakt., I Abt., Orig., *124*, 1932, 269.) From beet leaves.

Bacillus rarus Werner. (Cent. f. Bakt., II Abt., *87*, 1933, 456.) Good growth on Ca n-butyrate agar. One culture isolated from forest soil of Germany.

Bacillus repens Gibson. (Cent. f. Bakt., II Abt., *92*, 1935, 370.) Decomposes urea. Eight strains isolated from soil.

Bacillus reptans Ghosh. (Compt. rend. Soc. Biol., Paris, *86*, 1922, 914.) From a case of appendicitis.

Bacillus retaneus Grohmann. (Morphologisch- biologische Beiträge zur Kenntnis der Wasserstoffbakterien, Inaug. Diss., Univ. Leipzig, 1923; Cent. f. Bakt., II Abt., *61*, 1924, 267; Ruhland and Grohmann, Jahrb. wissensch. Botanik, *63*, 1924, 321.) Oxidizes hydrogen in the presence of oxygen to form water. Presumably widely distributed in soil.

Bacillus retiformis Migula. (Netzbacillus, Maschek, Bakt. Untersuch. d. Leitmeritzer Trinkwässer, Leitmeritz, 1887; Migula, Syst. d. Bakt., *2*, 1900, 712.) From water.

Bacillus robustus Weiss. (Weiss, Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 247; not *Bacillus robustus* Blau, Cent. f. Bakt., II Abt., *15*, 1905, 134.) From fermenting beets.

Bacillus ruber Zimmermann. (Zimmermann, Die Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *1*, 1890, 24; not *Bacillus ruber* Cohn, Beitr. z. Biol. d. Pflanz., *1*, Heft 3, 1875, 181; *Bacillus pseudoruber* Migula, Syst. d. Bakt., *2*, 1900, 850; *Erythrobacillus ruber* Holland, Jour. Bact., *5*, 1920, 223, line 15; *Serratia rubra* Bergey et al., Manual, 1st ed., 1923, 92; *Chromobacterium ruber* Topley and Wilson, Princip. of Bact. and Immun., *1*, 1931, 402.) From Chemnitz tap water. Spherical spores. See Manual, 5th ed., 1939, 607 for a description of this species.

Bacillus rufescens Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 178.) Characterized by good growth on Ca n-butyrate agar. One culture isolated from garden soil of Germany.

Bacillus rufulus Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 59.) Isolated 3 times from garden air.

Bacillus rugosus Henrici. (Henrici, Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 28; not *Bacillus rugosus* Wright, Mem. Nat. Acad. Sci., *7*, 1895, 438; not *Bacillus rugosus* Chester, Man. Determ. Bact., 1901, 220.) From Swiss cheese.

Bacillus rugulosus Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 181.) One of a

group of species described as growing well on Ca n-butyrate agar. Three strains isolated from soils of Germany, Cuba, and Italy.

Bacillus sacchari Jansc. (Mededeel. uit's Lands. Plantentuin, *9*, 1891, 1.) Reported to cause sereh, a disease affecting sugar cane (*Saccharum officinarum*). Went (Arch. voor de Java Suikerindustrie, 1895, 589) regards this as probably *Bacillus subtilis*.

Bacillus saccharolyticus Nepomnjatschjaja and Libermann. (Jour. f. Mikrobiol., Ukraine, *5*, 1938, 57; abst. in Cent. f. Bakt., II Abt., *101*, 1940, 81.) From plum preserves. A gas-producing rod.

Bacillus saccobranchi Dobell. (Quart. Jour. Micro. Sci., *56*, 1911, 441.) From heart blood of a fish (*Saccobranchus fossilis*).

Bacillus santiagensis Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 188.) Good growth on Ca n-butyrate agar. One culture isolated from Cuban soil.

Bacillus saprogenes Migula. (*Bacillus saprogenes vini III*, Kramer, Bakteriologie in ihren Beziehungen zur Landwirtschaft, *2*, 1892, 137; Migula, Syst. d. Bakt., *2*, 1900, 572; not *Bacillus saprogenes I*, *II* and *III*, Herfeldt, Cent. f. Bakt., II Abt., *1*, 1895, 77; not *Bacillus saprogenes* Salus, Arch. f. Hyg., *51*, 1904, 115.) From wine.

Bacillus saprogenes Chester. (*Bacillus saprogenes vini VI*, Kramer, Bakteriol. Landwirtsch., *2*, 1892, 139; Chester, Man. Determ. Bact., 1901, 289; not *Bacillus saprogenes* Trevisan, I generi e le specie delle Batteriacee, 1889, 17.) From wine.

Bacillus scaber (Duclaux) Trevisan. (*Tyrothrix scaber* Duclaux, Ann. Inst. Nat. Agron., *4*, 1882, 23; Trevisan, I generi e le specie delle Batteriacee, 1889, 16.) From milk.

Bacillus schottelii Trevisan. (Darmbacillus, Lydtin and Schottelius, Der Rotlauf der Schweine, Weisbaden, 1885, 214; *Bacillus coprogenes foetidus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 305; Trevisan, I generi e le specie delle Batteriacee, 1889, 17; *Bacterium coprogenes* Migula, Syst. d. Bakt., *2*, 1900, 327; *Bacterium schottelii* Chester, Man. Determ. Bact., 1901, 197.) From the intestinal contents of swine.

Bacillus segetalis Werner. (Cent. f. Bakt., II Abt., *87*, 1933, 467.) Characterized by growth on Ca n-butyrate agar. One strain isolated from soil in Germany.

Bacillus septico-aerobius Hauduroy et al. (Bacille septique aérobie, Legros, Thèse Méd., Paris, 1902; Hauduroy et al., Dict. d. Bact. Path., 1937, 46.) Aerobic, facultative. From a case of acute gaseous gangrene.

Bacillus septicus insectorum Krassilstschik. (Memoires de la Soc. Zool. de France, *6*, 1893, 250.) From cockchafer larvae (*Melolontha melolontha*).

Bacillus serrulatus Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 193.) Only moderate growth on Ca n-butyrate agar. One culture isolated from Cuban soil.

Bacillus sesami Malkoff. (Cent. f. Bakt., II Abt., *16*, 1906, 665.) Pathogenic on sesame (*Sesamum*).

Bacillus siccus Chester. (Bacillus No. 25, Conn, Storrs Agr. Exp. Sta. Rept., 1893, 63; Chester, Man. Determ. Bact., 1901, 284.) From milk.

Bacillus similis Schroeter. (Bacillus II, Bienstock, Ztschr. f. klin. Med., *8*, 1884, Heft 1 and 2; Schroeter, in Cohn, Kryptog.-Flora v. Schlesien, *3*, 1, 1886, 160; *Bacillus coprocinus* Trevisan, I generi e le specie delle Batteriacee, Milan, 1889, 15; *Bacillus faecalis* No. II, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 215; *Bacterium simile* Chester, Man. Determ. Bact., 1901, 197.) From feces.

Bacillus similis Eckstein. (Arch. f. Forst- u. Jagdwesen, *26*, 1894, 11.) From infected larvae of the nun moth (*Lymantria monacha*), etc.

Bacillus similityphosus Migula. (Typhusähnlicher Bacillus, Maschek, Bakt. Untersuch. d. Leitmeritz. Trinkwässer, Leitmeritz, 1887; Migula, Syst. d. Bakt., *2*, 1900, 730.) From water.

Bacillus sinapivagus Kossowicz. (Cent. f. Bakt., II Abt., *23*, 1909, 241.) From pickles.

Bacillus sombrosus Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 429.) From the stomach of a bird.

Bacillus sorghi Burrill. (The Microscope, *7*, 1887, 321; Proc. Amer. Soc. Microscopists, 1888, 193; *Bacterium sorghi* Chester, Delaware Agr. Exp. Sta. Ann. Rept., *9*, 1897, 127; Elliott and Smith, Jour. Agr. Res., *38*, 1928, 1.) Reported to cause a disease of sorghum (*Holcus sorghum*).

Bacillus sotto Paillot. (Sotto-Bacillus, Ischivata, quoted from Aoki and Chigasaki, Mitteil. d. Med. Fakul. d. k. Univ. z. Tokyo, *13*, 1915, 419 and *14*, 1915, 59; *Bacterium sotto* Metalnikov and Chorine, Internat. Corn Borer Invest., Sci. Repts., *1*, 1928, 56; Paillot, *ibid.*, *1*, 1928, 77–106.) From silkworms (*Bombyx mori*). Sotto is Japanese for "plötzlich hinfallen".

Bacillus spatiosus Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 56.) Isolated once from garden air.

Bacillus spermatozoides Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 13.) From dead moths (*Hyponomeuta evonymella*).

Bacillus sphaerosporus Beijerinck. (Cent. f. Bakt., II Abt., *25*, 1909, 45.) This organism has round terminal spores and produces nitrous oxide from nitrates. From garden soil.

Bacillus sphaerosporus calco-aceticus Beijerinck (*loc. cit.*, 46). A variety of the above having spherical to ellipsoidal spores.

Bacillus spinosporus Soriano. (Thesis, Univ. Buenos Aires, 1935, 562.) Spores spinate like some strains of *Bacillus polymyxa*. No gas formed. One strain isolated from soil.

Bacillus spiralis Migula. (Syst. d. Bakt., *2*, 1900, 624.) From water.

Bacillus spirogyra Dobell. (Quart. Jour. Micro. Sci., *53*, 1909, 579 and *56*, 1911, 434.) From large intestine of frog (*Rana temporaria*) and toad (*Bufo vulgaris*).

Bacillus spongiosus Aderhold and Ruhland. (Cent. f. Bakt., II Abt., *15*, 1905, 376.) Found in the gum masses discharged by cherry trees.

Bacillus sporonema Schaudinn. (Arch. f. Protistenkunde, *2*, 1903, 421.) From sea water.

Bacillus spurius Grohmann. (Morphologisch-biologische Beiträge zur Kenntnis der Wasserstoffbakterien, Inaug. Diss., Univ. Leipzig, 1923; Cent. f. Bakt., II Abt., *61*, 1924, 267; Ruhland and Grohmann, Jahrb. wissensch. Botanik, *63*, 1924, 321.) Oxidizes hydrogen in the presence of oxygen to form water. Presumably widely distributed in soil.

Bacillus sputi Chester. (Bacillus No. 6, Pansini, Arch. f. path. Anat., *122*, 1890, 442; Chester, Man. Determ. Bact., 1901, 280.) From sputum.

Bacillus squamiformis Saito. (Jour. Coll Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 54.) Isolated 9 times from garden soil.

Bacillus stellaris Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 52.) Isolated 6 times from garden air.

Bacillus stellatus Zimmermann. (Zimmermann, Bakt. unserer Trink- u. Nutzwässer, II Reihe, 1894, 14; not *Bacillus stellatus* Chester, Man. Determ. Bact., 1901, 274; not *Bacillus stellatus* Vincent, Ann. Inst. Past., *21*, 1907, 62.) From water.

Bacillus streptoformis Migula. (Salpeter zerstörenden Bacillus, Schirokikh, Cent. f. Bakt., II Abt., *2*, 1896, 204; Migula, Syst. d. Bakt., *2*, 1900, 682; *Bacillus schirokikhi* Chester, Man. Determ. Bact., 1901, 252; *Bacillus denitrificans* Chester, *ibid.*, 274.) From horse feces. Utilizes potassium nitrate.

Bacillus suaveolens Sclavo and Gosio. (Quoted from Omeliansky, Jour. Bact., *8*, 1923, 398.) No source given.

Bacillus subcuticularis Migula. (*Bacillus cuticularis albus* Tataroff, Inaug. Diss., Dorpat, 1891, 24; Migula, Syst. d. Bakt., *2*, 1900, 623; *Bacillus cuticularis* Chester, Man. Determ. Bact., 1901, 285.) From water.

Bacillus sublanatus Wright. (Mem. Nat. Acad. Sci., *7*, 1895, 455.) From water.

Bacillus sublustris Schieblich. (Cent. f. Bakt., II Abt., *58*, 1923, 206.) Commonly isolated from green and fermenting fodders.

Bacillus submarinus ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 267.) Central ovate spores. From marine bottom deposits.

Bacillus (*Streptobacter*) *subtiliformis* Schroeter. (*Bacillus I*, Bienstock, Ztschr. f. klin. Med., *8*, Heft 1 and 2, 1884; Schroeter, in Cohn, Kryptog.-Flora v. Schlesien, *3*, 1, 1886, 160; *Bacillus mesenthericus* (sic) Trevisan, I generi e le specie delle Batteriacee, Milan, 1889, 15; not *Bacillus mesentericus* Trevisan, *ibid.*, 19; *Bacillus subtilis simulans I*, Eisenberg, Bakt. Diag., 3 Aufl., 1891, 189; *Bacillus faecalis* No. I, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 215; *Bacterium subtile* Migula, Syst. d. Bakt., *2*, 1900, 292; *Bacterium subtiliforme* Chester, Man. Determ. Bact., 1901, 197.) From feces.

Bacillus succinicus Fitz. (Quoted from DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 966.) From infusions.

Bacillus suffuscus Grohmann. (Morphologisch-biologische Beiträge zur Kenntnis der Wasserstoffbakterien, Inaug. Diss., Univ. Leipzig, 1923; Cent. f. Bakt., II Abt., *61*, 1924, 267; Ruhland and Grohmann, Jahrb. wissensch. Botanik, *63*, 1924, 321.) Oxidizes hydrogen in the presence of oxygen to form water. Presumably widely distributed in soil.

Bacillus supraresistans Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 185.) Very good growth on Ca n-butyrate agar. One culture isolated from soil in Germany.

Bacillus surgeri Dornic and Daire. (Bull. mensuel de l'Office de renseignements agricoles, *6*, 1907; abst. in Rev. Gén. du Lait., *6*, 1907, 164.) Spores not observed but author stated that they were probably present because this species could withstand 85°C for 5 minutes. From whey.

Bacillus tabaci III, Koning. (Tijdschr. voor toegepaste scheikunde en hygiene. Deel 1, 1897. See Behrens, Mykologie der Tabakfabrikation, in Lafar, Handbuch der techn. Mykologie, *5*, 1905, 11.) Thermophilic. Probably from soil.

Bacillus tardivus Stührk. (Cent. f. Bakt., II Abt., *93*, 1935, 177.) Very slight growth on Ca n-butyrate agar. One culture isolated from garden soil of Germany.

Bacillus technicus Morikawa and Prescott. (Jour. Bact., *13*, 1927, 58; also see Morikawa, Bull. Agr. Chem. Soc. Japan, *3*, 1927, 28.) Produces butyl and isopropyl alcohols. Source not given.

Bacillus tenax Eckstein. (Ztschr. f. Forst- u. Jagdwesen, *26*, 1894, 14.) From larvae of the nun moth (*Lymantria monacha*).

Bacillus tenuis non-liquefaciens Choukévitch. (Ann. Inst. Past., *25*, 1911, 352.) From large intestine of horse.

Bacillus terminalis Migula. (Bacillus No. XII, Flügge, Ztschr. f. Hyg., *17*, 1894, 296; *Bacillus lactis* No. XII, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 269; Migula, Syst. d. Bakt., *2*, 1900, 578; *Bacillus lacteus* Chester, Man. Determ. Bact., 1901, 291.) From milk. A duplicate of *Bacterium sempervivum* Migula.

Bacillus terminalis var. *thermophilus* Prickett. (N. Y. Agr. Exp. Sta. Tech. Bull. 147, 1928, 44.) Produces a brown water soluble pigment on agar; optimum temperature 55°C to 65°C. Fourteen strains from raw and pasteurized milk, milk powder, and skin of a cow.

Bacillus terrestris Werner. (Cent. f. Bakt., II Abt., *87*, 1933, 461.) Weak growth on Ca n-butyrate agar. Two strains isolated from soils of Germany.

Bacillus tetanoides Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 49.) Isolated once from garden air.

Bacillus thalassokoites ZoBell and Upham. (Bull. Scripps Inst. of Oceanography, Univ. Calif., *5*, 1944, 268.) Central spores. From marine bottom deposits.

Bacillus theae Hori and Bokura. (Jour. Plant Protection, Tokyo, *2*, 1915, 1.) Pathogenic for tea (*Thea sinensis*).

Bacillus thermoabundans Beaver. (Dissertation, Ohio State University, Columbus, 1932, 31.) Thermophilic, subterminal spores. Growth at 55°C, less growth at 37°C. From malted milk powder.

Bacillus thermoacetigenitus Beaver, *loc. cit.*, 25. Thermophilic, central spores. No growth at 37°C. From vinegar.

Bacillus thermoacidificans Renco. (Ann. Microbiol., *2*, 1942, 000.) From Grana cheese whey. This is stated by Gorini (R. Ist. Lombardo Sci. e. Lett., Rend., *76*, 7ᵉ della Ser. 3, 1942, 3) to be the same as *Bacillus lactis termophilus* Gorini.

Bacillus thermoactivus Beaver, *loc. cit.*, 27. Thermophilic, central spores. No growth at 37°C. From home-canned beets.

Bacillus thermoannulatus Beaver, *loc. cit.*, 17. Thermophilic, subterminal spores. No growth at 37°C. From commercially canned tomatoes.

Bacillus thermoaquatilis Beaver, *loc. cit.*, 18. Thermophilic, subterminal spores. No growth at 37°C. From a warm spring at Springfield, Ohio.

Bacillus thermoarborescens Beaver, *loc. cit.*, 30. Thermophilic, sub-terminal to central spores. Growth at 55°C, less growth at 37°C. From candy.

Bacillus thermobutyrosus Beaver, *loc. cit.*, 15. Thermophilic, subterminal spores. No growth at 37°C. From commercially canned tomatoes.

Bacillus thermocompactus Beaver, *loc. ict.*, 20. Thermophilic, subterminal spores. No growth at 37°C. From red grapes stored in sawdust.

Bacillus thermodactylogenitus Beaver, *loc. cit.*, 28. Thermophilic, central to subterminal spores. Growth at 37°C and 55°C. From commercially packed dates.

Bacillus thermoeffervescens Beaver, *loc. cit.*, 23. Thermophilic, central spores. No growth at 37°C. From commercially canned peas.

Bacillus thermofaecalis Beaver, *loc. cit.*, 30. Thermophilic, subterminal spores. Growth at 55°C. From feces of robin.

Bacillus thermofibrincolus Itano and Arakawa. (Ber. d. Ohara Inst. f. landwirsch. Forschungen, Japan, *4*, 1929, 265.) Thermophilic; decomposes cellulose. From soil containing decomposed leaves.

Bacillus thermofiliformis Beaver, *loc. cit.*, 22. Thermophilic, subterminal spores. No growth at 37°C. From commercially canned peas.

Bacillus thermograni Beaver, *loc. cit.*, 16. Thermophilic, subterminal spores. No growth at 37°C. From commercially canned corn.

Bacillus thermolongus Beaver, *loc. cit.*, 19. Thermophilic, subterminal spores. No growth at 37°C. From commercially canned tomatoes.

Bacillus thermolubricans Beaver, *loc. cit.*, 26. Thermophilic, central spores. No growth at 37°C. From lubricating oil.

Bacillus thermononodorus Beaver, *loc. cit.*, 26. Thermophilic, central spores. No growth at 37°C. From tap water.

Bacillus thermonubilosus Beaver, *loc. cit.*, 19. Thermophilic, subterminal spores. No growth at 37°C. From soil, Yellow Springs, Ohio.

Bacillus thermoodoratus Beaver, *loc. cit.*, 29. Thermophilic, central spores. Growth at 55°, less growth at 37°C. From spoiled gelatin.

Bacillus thermopellitus Beaver, *loc. cit.*, 22. Thermophilic, central spores. No growth at 37°C. From old sour milk.

Bacillus thermophilus Miquel. (Miquel, Ann. d. Micrtypes., *1*, 1888, 4; *Bacillus thermophilus miquelii* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 269; *Bacterium termophilum* (sic) Migula, Syst. d. Bakt., *2*, 1900, 342; *Bacterium miquelii* Chester, Man. Determ. Bact., 1901, 186.) From the

intestine, water and soil. Thermophilic. No growth below 40°C.

Bacillus thermophilus sojae Rokusho and Fukutome. (Jour. Agr. Chem. Soc., Japan, *13*, 1937, 1235.) From spontaneously heating soy-bean cake.

Bacillus thermosuavis Beaver, *loc. cit.*, 24. Thermophilic, central spores. No growth at 37°C. From commercially canned mincemeat.

Bacillus thermotenax Beaver, *loc. cit.*, 28. Thermophilic, subterminal spores. Growth at 37°C and 55°C. From ground horseradish.

Bacillus thermourinalis Beaver, *loc. cit.*, *16*. Thermophilic, subterminal spores. No growth at 37°C. From human urine.

Bacillus thermoviscidus Beaver, *loc. cit.*, 21. Thermophilic, subterminal spores. No growth at 37°C. From fresh pig ovary.

Bacillus thoracis Howard. (Gleanings in Bee Culture, *28*, 1900, 124.) From black brood of the honey bee (*Apis mellifera*).

Bacillus tracheitis sive *graphitosis* Krassilstschik. (Memoires de la Soc. Zool. de France, *6*, 1893, 250.) From diseased larvae of the cockchafer (*Melolontha melolontha*).

Bacillus tricomii Trevisan. (Bacillo della gangraena senilis, Tricomi, Riv. internaz. di Med. e Chir., *3*, 1886, 73; Trevisan, I generi e le specie delle Batteriacee, 1889, 13; *Bacterium tricomii* Migula, Syst. d. Bakt., *2*, 1900, 310.) From a case of senile gangrene.

Bacillus trifolii Voglino. (Ann. R. Accad. Agr. Torino, *39*, 1896, 85.) Pathogenic for clover (*Trifolium pratense*, *T. repens*, *T. resupinatum*).

Bacillus tritus Batchelor. (Jour. Bact., *4*, 1919, 29.) One culture from feces.

Bacillus tuberis von Wahl. (Cent. f. Bakt., II Abt., *16*, 1906, 503.) From cooked truffles (*Tuber oestivum*).

Bacillus tuberosus Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 248.) From fermenting beets.

Bacillus tubifex Dale. (Annals of Bot., *26*, 1912, 133.) Reported to cause a leaf disease of potato (*Solanum tuberosum*) and tomato (*Lycopersicum esculentum*).

Bacillus turgidus (Duclaux) Trevisan. (*Tyrothrix turgidus* Duclaux, Ann. Inst. Nat. Agron., *4*, 1882, 23; Trevisan, I generi e le specie delle Batteriacee, 1889, 16.) From milk.

Bacillus tympani-cuniculi Morcos. (Jour. Bact., *23*, 1932, 454.) Causes tympanitis in young rabbits.

Bacillus ubicuitarius Soriano. (Estudio sistematico de algunas bacterias esporuladas aerobias, Thesis, Univ. Buenos Aires, 1935, 569.) Four cultures isolated from soil.

Bacillus ulna Cohn. (Cohn, Beitr. z. Biol. d. Pflanz., *1*, Heft 2, 1872, 177; also see Prazmowski, Untersuch. ü. d. Entwickelungsges. u. Fermentwirk. einiger Bakterienarten, Leipzig, 1880, 20.) Found once in an infusion of cooked egg-white.

Bacillus undulatus den Dooren de Jong. (Bull. Assoc. Diplômés de Microbiol. Nancy, No. 26–27, 1946, 12.) From soil.

Bacillus uvaeformis Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 415.) From the stomachs and intestines of birds.

Bacillus vaculatus Ravenel. (Mem. Nat. Acad. Sci., *8*, 1896, 31.) From soil.

Bacillus validus Heigener. (Cent. f. Bakt., II Abt., *93*, 1935, 97.) Four cultures isolated from soil from Germany, Cuba, and Egypt.

Bacillus valinovorans Heigener. (Cent. f. Bakt., II Abt., *93*, 1935, 104.) Good growth on valine agar. Five strains isolated from soils from Egypt, Germany, Italy, and Palestine.

Bacillus varians Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 50.) Isolated 11 times from garden air.

Bacillus ventricosus Heigener. (Cent.

f. Bakt., II Abt., *93*, 1935, 102; not *Bacillus ventricosus* Weiss, Arb. bakt. Inst. Karlsruhe, *2*, 1898, 233.) One culture isolated from soil from Italy.

Bacillus ventriculus Koch. (Botan. Zeitung, *46*, 1888, 341.) From slices of carrot exposed to the air. Formed two spores in a spindle-shaped sporangium.

Bacillus vernicosus Zimmermann. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, II Reihe, 1894, 46; not *Bacillus vernicosus* Migula, Syst. d. Bakt., *2*, 1900, 781.) From waste water.

Bacillus verticillatus Ravenel. (Ravenel, Mem. Nat. Acad. Sci., *8*, 1896, 13; *Bacterium verticillatum* Chester, Man. Determ. Bact., 1901, 192.) From soil.

Bacillus vesicae Migula. (*Bacillus septicus vesicae* Clado, quoted from Eisenberg, Bakt. Diag., 3 Aufl., 1891, 341; Migula, Syst. d. Bakt., *2*, 1900, 620.) From urine in a case of cystitis. Probably is *Bacillus cladoi* Trevisan.

Bacillus villosus Zimmermann. (Bakt. unserer Trink- u. Nutzwässer, Chemnitz, II Reihe, 1894, 38; not *Bacillus villosus* Keck, Inaug. Diss., Dorpat, 1890, 47.) From water.

Bacillus violaceus Eisenberg. (Bakt. Diag., 2 Aufl., 1888, 8; not *Bacillus violaceus* Schroeter, Kryptogamen-Flora von Schlesien, *3*, 1886, 157; not *Bacillus violaceus* Frankland and Frankland, Ztschr. f. Hyg., *6*, 1888, 394.) Said to produce central spores. From water.

Bacillus viridi-glaucescens Sack. (Cent. f. Bakt., II Abt., *65*, 1925, 113.) From several kinds of soil.

Bacillus viridiluteus Pagliani et al. (Grüngelber, nicht verflüssiger Bacillus, Eisenberg, Bakt. Diag., 1 Aufl., 1886, Tab. 6; Pagliani, Maggiora and Fratini, Soc. ital. d'igiene, 1887, 586, see Trevisan, I generi e le specie delle Batteriacee, 1889, 19). From water.

Bacillus viscosus bruxellensis van Laer. (Cent. f. Bakt., II Abt., *23*, 1909, 159.) From beer wort.

Bacillus viticola Burgwitz. (*Bacillus vitis* Merjanian and Kovaleva, Prog. Agric. et Vitic., *95*, 1930, 594 and *96*, 1931, 17; not *Bacillus vitis* Montemartini, Rev. Patol. Veg., *6*, 1913, 175; Burgwitz, Phytopath. Bacteria, Leningrad, 1935, 37.) Pathogenic for the grape vine.

Bacillus vitreus Migula. (No. 11, Lembke, Arch. f. Hyg., *26*, 1896, 306; Migula, Syst. d. Bakt., *2*, 1900, 569.) From the intestines of infants.

Bacillus vogelii Migula. (Roter Kartoffelbacillus, Vogel, Ztschr. f. Hyg., *26*, 1897, 404; Migula, Syst. d. Bakt., *2*, 1900, 556; *Bacillus viscosus* Chester, Man. Determ. Bact., 1901, 286; not *Bacillus viscosus* Frankland and Frankland, Ztschr. f. Hyg., *6*, 1889, 391.) From stringy bread.

Bacillus watzmannii Werner. (Cent. f. Bakt., II Abt., *87*, 1933, 462.) Weak growth on Ca n-butyrate agar. One culture isolated from soil of Germany.

Bacillus weigmanni Migula. (Bakterie II, Weigmann and Zirn, Cent. f. Bakt., *15*, 1894, 465; Migula, Syst. d. Bakt., *2*, 1900, 693.) From soapy milk.

Bacillus xylanicus Patrick and Werkman. (Iowa State Coll. Jour. Sci., *7*, 1933, 415.) Ferments xylan. One culture isolated from decayed apple wood.

Bacillus xylophagus Patrick and Werkman. (Iowa State Coll. Jour. Sci., *7*, 1933, 414.) Ferments xylan. One culture isolated from decayed apple wood.

Bacillus zirnii Migula. (Bakterie III, Weigmann and Zirn, Cent. f. Bakt., *15*, 1894, 466; Migula, Syst. d. Bakt., *2*, 1900, 693.) From soapy milk.

Bacterium adametzii Migula. (Bacillus No. XIV, Adametz, Landwirtsch. Jahrb., *18*, 1889, 246; Migula, Syst. d. Bakt., *2*, 1900, 338; *Bacterium rugosum* Chester, Man. Determ. Bact., 1901, 194.) From cheese.

Bacterium aloes Passalacqua. (Rev. Pat. Veg., *19*, 1929, 110.) From diseased aloes.

Bacterium angulans Burchard. (Inaug. Diss., 1897; Arb. bakt. Inst. Karlsruhe, *2*, Heft 1, 1902, 43.) From water.

Bacterium aqueum Migula. (*Bacillus thermophilus VIII*, Rabinowitsch, Ztschr. f. Hyg., *20*, 1895, 160; Migula,

Syst. d. Bakt., *2*, 1900, 345; *Bacterium thermophilum VIII*, Chester, Man. Determ. Bact., 1901, 186.) From feces and corn.

Bacterium articulatum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1897, 445.) From the stomach and intestines of birds.

Bacterium asparagi von Wahl. (Von Wahl, Cent. f. Bakt., II Abt., *16*, 1906, 498; *Bacillus asparagi* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 436.) From boiled asparagus.

Bacterium brachysporum Burchard. (Inaug. Diss., 1897; Arb. bakt. Inst. Karlsruhe, *2*, Heft 1, 1902, 20.) From bakery bread.

Bacterium canadensis Chorine. (Internat. Corn Borer Invest., Sci. Rpts., *2*, 1929, 39; also Ann. Inst. Past., *43*, 1929, 1658; *Bac. canadensis* Chorine and Metalnikov, Ann. Inst. Past., *43*, 1929, 1392; also Paillot, L'infection chez les insectes, 1933, 134 where *Bac.* equals *Bacterium*, see index p. 522; *Bacillus canadensis* Steinhaus, Bacteria Associated Extracellularly with Insects, Minneapolis, 1942, 50.) In its general characters said to resemble *Bacillus megatherium* and other bacteria isolated from insects (*Bacillus thuringiensis*, *Bacillus hoplosternus*, etc.). Pathogenic for larvae of *Pyrausta nubilalis*, *Galleria mellonella*, and *Ephestia kuhniella*. From diseased larvae of the corn borer.

Bacterium cattleyae Pavarino. (Atti R. Accad. Naz. Lincei Rend. Cl. Sci. Fis., Mat. e. Nat., *20*, 1911, 233.) From diseased orchids.

Bacterium cazaubon Metalnikov. (Compt. rend. Soc. Biol., Paris, *105*, 1930, 536; two varieties, *Bacterium cazaubon* I and II, are recognized by Metalnikov, Ermolaev and Schobaltzyn, Internat. Corn Borer Invest., Sci. Repts., *3*, 1930, 30 and Ann. Inst. Past., *46*, 1931, 469.) From diseased corn borer larvae (*Pyrausta nubilalis* Hb.).

Bacterium christiei Chorine. (Internat. Corn Borer Invest., Sci. Rpts., *2*, 1929, 46; also Ann. Inst. Past., *43*, 1929, 1666.) According to the author, this closely resembles *Bacterium ontarioni*. Several strains isolated from diseased corn borers.

Bacterium colomatii Chester. (Colomatii, Breslauer arztliche Ztschr., 1883, No. 4; Chester, Man. Determ. Bact., 1901, 186.) From xerotic masses in conjunctivitis.

Bacterium deliense Swellengrebel. (Archiv f. Protist., *31*, 1913, 277.) Observed in stained smears from the spleen of diseased cattle but not isolated. Two spores may form in a single cell if division is delayed.

Bacterium ephestiae No. 1 and No. 2 Metalnikov and Chorine. (Ann. Inst. Past., *43*, 1929, 1394.) Not pathogenic for corn borer although the size of the larvae was reduced. Later, Ellinger and Chorine (Internat. Corn Borer Investigations, Sci. Rpts., *3*, 1930, 37) identified these as strains of *Bacillus thuringiensis*. From diseased larvae of *Ephestia kuehniella*.

Bacterium filiforme Henrici. (Henrici, Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 41; not *Bacterium filiforme* Migula, Syst. d. Bakt., *2*, 1900, 296; *Bacterium subfiliforme* Migula, *ibid.*, 297.) From Swiss cheese.

Bacterium galleriae No. 1, Chorine. (Bâtonnet mince, Metalnikov, Compt. rend. Acad. Sci., Paris, *175*, 1922, 69; Chorine, Ann. Inst. Past., *41*, 1927, 1115.) From diseased larvae of the bee moth (*Galleria mellonella*).

Bacterium galleriae Chorine. (Plus grand bâtonnet, Metalnikov, Compt. rend. Acad. Sci., Paris, *175*, 1922, 70; Chorine, Compt. rend. Soc. Biol., Paris, *95*, 1926, 200; *Bacterium galleriae No. 2*, Chorine, Ann. Past. Inst., *41*, 1927, 1117.) From diseased larvae of the bee moth (*Galleria mellonella*). Resembles *Bacillus megatherium*. Pathogenic for the corn borer (Internat. Corn Borer Invest., Sci. Repts., *1*, 1927, 46).

Bacterium galleriae No. 3, Chorine. (Ann. Inst. Past., *41*, 1927, 1118.) From diseased larvae of the bee moth (*Galleriae mellonella*). Resembles *Bacillus subtilis* and *Bacillus mesentericus*.

Bacterium giganteum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 453.) From the stomach and intestines of birds.

Bacterium glaucescens Migula. (*Bacillus thermophilus VI*, Rabinowitsch, Ztschr. f. Hyg., *20*, 1895, 158; Migula, Syst. d. Bakt., *2*, 1900, 344; *Bacterium thermophilum VI*, Chester, Man. Determ. Bact., 1901, 185.) From feces.

Bacterium glutinosum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 441.) From the stomach of a dove.

Bacterium ilidzense Migula. (*Bacillus ilidzensis capsulatus* Karlinski, Hygienische Rundschau, *5*, 1895, 688; Migula, Syst. d. Bakt., *2*, 1900, 340.) From the water of a hot spring. Thermophilic.

Bacterium implectans Burchard. (Inaug. Diss., 1897; Arb. bakt. Inst. Karlsruhe, *2*, Heft 1, 1898, 29.) From drinking water.

Bacterium insulosum Wilhelmy. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 16.) From meat extract.

Bacterium insulum Weiss. (Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 252.) From fermenting malt.

Bacterium intactum Migula. (*Bacillus thermophilus V*, Rabinowitsch, Ztschr. f. Hyg., *20*, 1895, 158; Migula, Syst. d. Bakt., *2*, 1900, 344; *Bacterium thermophilum V*, Chester, Man. Determ. Bact., 1901, 185.) From feces and corn.

Bacterium iris Migula. (Irisierender Bacillus, Tataroff, Inaug. Diss., Dorpat, 1891, 57; Migula, Syst. d. Bakt., *2*, 1900, 313; not *Bacterium iris* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 125.) From water.

Bacterium italicum No. 1 and No. 2, Metalnikov, Ermolaev and Skobaltzyn. (Ann. Inst. Past., *46*, 1931, 470; No. 2 is also described in Internat. Corn Borer Invest. Sci. Repts., *3*, 1930, 30.) From larvae of the corn borer (*Pyrausta nubilalis*).

Bacterium longum Kern. (Kern, Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1894, 391; *Bacterium squamosum longum* Kern, *ibid.*, 458; *Bacillus squamosus longus* Chorine, Ann. Inst. Past., *41*, 1927, 1114.) From the intestines of a dove (*Columba oenas*).

Bacterium lunula Dobell. (Quart. Jour. Micro. Sci., *53*, 1909, 579.) From rectum of the toad (*Bufo vulgaris*). Resembles *Bacterium binucleatum* Swellengrebel.

Bacterium lydiae Migula. (*Bacillus thermophilus I*, Rabinowitsch, Ztschr. f. Hyg., *20*, 1895, 156; Migula, Syst. d. Bakt., *2*, 1900, 343; *Bacterium thermophilum I*, Chester, Man. Determ. Bact., 1901, 185.) Widely distributed in soil, snow, feces, corn.

Bacterium mansfieldii Chester. (Bacillus No. 18, Conn, Storrs Agr. Expt. Sta., 1893, 51; Chester, Man. Determ. Bact., 1901, 197.) From milk.

Bacterium markusfeldii Chester. (Bacillus der trichorrhexis nodosa, Markusfeld, Cent. f. Bakt., I Abt., *21*, 1897, 230; Chester, Man. Determ. Bact., 1901, 192.) Associated with the disease, trichorrhexis nodosa.

Bacterium mesentericum Migula. (*Bacillus mesentericus panis viscosi I*, Vogel, Ztschr. f. Hyg., *26*, 1897, 404; Migula, Syst. d. Bakt., *2*, 1900, 314; *Bacterium panis* Chester, Man. Determ. Bact., 1901, 196.) From stringy bread dough.

Bacterium mesenteroides Migula. (Bacillus No. XVII, Adametz, Landw. Jahrb., *18*, 1889, 249; Migula, Syst. d. Bakt., *2*, 1900, 312; *Bacterium viscosum* Chester, Man. Determ. Bact., 1901, 194.) From cheese.

Bacterium modestum Bersteyn. (Arb. bakt. Inst. Karlsruhe, *3*, 1903, 95.) From soil.

Bacterium monstrosum Henrici. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 47.) From Swiss cheese.

Bacterium nephritidis Migula. (*Bacillus nephritidis interstitialis* Letzerich, Ztschr. f. klin. Med., *13*, 188–, 33; Migula, Syst. d. Bakt., *2*, 1900, 310; not *Bacterium nephritidis* Chester, Man. Determ. Bact., 1901, 145.) From urine in cases of nephritis.

Bacterium ochraceum Migula. (*Bacillus viscosus ochraceus* Freund, Martin

Inaug. Diss., Erlangen, 1893, 37; Migula, Syst. d. Bakt., *2*, 1900, 333.) From the oral cavity.

Bacterium olivae Montemartini. (Atti Inst. Bot. Pavia Univ., 2 ser., *14*, 1914, 154.) From diseased olive branches.

Bacterium paludosum McBeth. (Soil Sci., *1*, 1916, 463.) Filter paper reduced to a white pulp-mass. From two soils in California.

Bacterium perittomaticum Burchard. (Arb. bakt. Inst. Karlsruhe, *2*, 1898, 11.) Similar to or identical with *Bacillus ruminatus* (Gottheil, Cent. f. Bakt., II Abt., *7*, 1901, 485). From soil.

Bacterium pituitans Burchard. (Inaug. Diss., 1897; Arb. bakt. Inst. Karlsruhe, *2*, Heft 1, 1898, 8.) From a brown concretion in a cooked egg.

Bacterium plicativum Weiss. (Weiss, Arb. bakt. Inst. Karlsruhe, *2*, Heft 3, 1902, 223; not *Bacterium plicativum* Migula, Syst. d. Bakt., *2*, 1900, v and 453.) From fermenting beets and malt.

Bacterium plicatum Henrici. (Henrici, Arb. bakt. Inst. Karlsruhe, *1*, Heft 1, 1894, 49; not *Bacterium plicatum* Chester, Man. Determ. Bact., 1901, 166.) From brick cheese.

Bacterium pseudaceti Migula. (Bacillus No. XV, Adametz, Landw. Jahrb., *18*, 1889, 247; Migula, Syst. d. Bakt., *2*, 1900, 320; *Bacterium turgidum* Chester, Man. Determ. Bact., 1901, 195.) From cheese. Characteristic involution forms very similar to those of *Bacillus aceti* Hansen.

Bacterium pseudomycoides Migula. (Migula, Syst. d. Bakt., *2*, 1900, 486; *Bacillus pseudomycoides roseus* Nepveux, Thèse, Fac. Pharm., Nancy, 1920, 112.) From soil.

Bacterium pseudovermiculosum Saito. (Jour. Coll. Sci., Imp. Univ., Tokyo, *23*, Art. 15, 1908, 62.) Isolated twice from garden air.

Bacterium pyrenei No. 1, No. 2 and No. 3, Metalnikov, Ermolaev and Skobaltzyn. (Internat. Corn Borer Invest., *3*, 1930, 28 and Ann. Inst. Past., *46*, 1931, 467, 468 and 469 respectively; presumably the same as *Bacillus pirenei* Pospelov, Lenin Acad. Agr. Sci. (U.S.S.R.), Ann. Rept. 1936, 318–321.) No. 1 from diseased larvae of the corn borer (*Pyrausta nubilalis*) that had become black after death; No. 2 from larvae that had become brown; and No. 3 from larvae that had become pinkish-brown.

Bacterium radiatum Kern. (Kern, Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 438; *Bacterium barbatum* Migula, Syst. d. Bakt., *2*, 1900, 317.) From the stomach of a finch.

Bacterium rusticum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 440.) From the stomach of a sparrow.

Bacterium sempervivum Migula. (No. XII, Flügge, Ztschr. f. Hyg., *17*, 1894, 296; *Bacillus lactis* No. XII, Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 269; Migula, Syst. d. Bakt., *2*, 1900, 321.) From milk.

Bacterium serratum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 451.) From the intestine of a dove.

Bacterium sewerini Migula. (Sewerin, Cent. f. Bakt., II Abt., *3*, 1897, 709; Migula, Syst. d. Bakt., *2*, 1900, 330.) From manure.

Bacterium spissum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 446.) From the intestine of a bird.

Bacterium sputicola Migula. (Bacillus No. 4, Pansini, Arch. f. path. Anat., *122*, 1890, 440; Migula, Syst. d. Bakt., *2*, 1900, 306; *Bacterium sputi* Chester, Man. Determ. Bact., 1901, 190.) From sputum.

Bacterium streptococciforme Migula. (*Bacillus thermophilus III*, Rabinowitsch, Ztschr. f. Hyg., *20*, 1895, 156; Migula, Syst. d. Bakt., *2*, 1900, 343; *Bacterium thermophilum III*, Chester, Man. Determ. Bact., 1901, 185.) From soil, feces, corn.

Bacterium subdenticulatum Migula. (*Bacillus thermophilus VII*, Rabinowitsch, Ztschr. f. Hyg., *20*, 1895, 158; Migula, Syst. d. Bakt., *2*, 1900, 345; *Bacterium thermophilum VII*, Chester, Man. Determ. Bact., 1901, 185.) From feces.

Bacterium subrubeum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 450; *Bacillus subrubeus* Nepveux, Thèse, Fac. Pharm., Nancy, 1920, 115.) From the intestines of birds.

Bacterium subsquamosum Migula. (*Bacterium squamosum longum* Kern, Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 458; Migula, Syst. d. Bakt., *2*, 1900, 335.) From the intestines of a dove.

Bacterium subthermophilum Migula. (*Bacillus thermophilus IV*, Rabinowitsch, Ztschr. f. Hyg., *20*, 1895, 157; Migula, Syst. d. Bakt., *2*, 1900, 344; *Bacterium thermophilum IV*, Chester, Man. Determ. Bact., 1901, 186.) From soil and feces.

Bacterium subtilis var. *galleriae* Chorine. (Ann. Inst. Past., *41*, 1927, 1120.) From diseased larvae of the bee moth (*Galleria mellonella*).

Bacterium tenax Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 443.) From the stomachs of birds.

Bacterium terrae (Ucke) Chester. (*Streptobacillus terrae* Ucke, Cent. f. Bakt., I Abt., *23*, 1898, 1001; Chester, Man. Determ. Bact., 1901, 199.) From soil.

Bacterium truncatum Chester. (Bacillus No. 51, Conn, Storrs Agr. Exp. Sta., 1894, 81; Chester, Man. Determ. Bact., 1901, 195; not *Bacterium truncatum* Migula, Syst. d. Bakt., *2*, 1900, 407; not *Bacterium truncatum* Chester, *ibid.*, 157.) From milk.

Bacterium verrucosum Kern. (Arb. bakt. Inst. Karlsruhe, *1*, Heft 4, 1896, 434.) From the stomachs and intestines of birds.

Bacterium virgula (Duclaux) Migula. (*Tyrothrix virgula* Duclaux, Ann. Inst. Nat. Agron., *4*, 1882, 23; Migula, Syst. d. Bakt., *2*, 1900, 323.) From cheese.

Bacterium viride van Tieghem. (Van Tieghem, Bull. Soc. Bot. France, 1880, 174; *Bacillus viridis* Trevisan, I generi e le specie delle Batteriacee, 1889, 18.)

Cellulobacillus mucosus Simola. (Ann. Ac. Sc. Fenn., Ser. A, *34*, 1931; abst. in Cent. f. Bakt., II Abt., *86*, 1932, 89.) Thermophilic; cellulose decomposed quickly at 55° to 60°C, more slowly at 37°C.

Cellulobacillus myxogenes Simola (*loc. cit.*). Not slimy as above.

Clostridium gelatinosum Laxa. (Eine thermophilen Bacillus, Laxa, Cent. f. Bakt., II Abt., *4*, 1898, 362; Laxa, *ibid.*, *6*, 1900, 286; *8*, 1902, 154; *Bacterium saccharophilum* Migula, Syst. d. Bakt., *2*, 1900, 341; *Bacterium laxae* Chester, Man. Determ. Bact., 1901, 187.) From sugar factory wastes. Produces slime in sucrose solutions. Probably a variety of *Bacillus vulgatus* according to Sacchetti (Cent. f. Bakt., II Abt., *95*, 1936, 115).

Denitrobacterium thermophilum Ambroz. (Cent. f. Bakt., II Abt., *37*, 1913, 3.) From soil.

Lactobacillus sporogenes Horowitz-Wlassowa and Nowotelnow. (Cent. f. Bakt., II Abt., *87*, 1933, 331.) Resembles *Lactobacillus delbrueckii* but forms ellipsoidal, terminal spores.

Metabacterium polyspora Chatton and Perard. (Compt. rend. Soc. Biol., Paris, *65*, 1913, 1232.) The type species of the genus *Metabacterium*, characterized by forming one to eight spores in a single cell. From the caecum of guinea pigs. See Buchanan (Jour. Bact., *3*, 1918, 39).

Myxobacillus betae Gonnermann. (Oesterreich-Ungarische Ztschr. f. Zuckerind. u. Landwirtsch., *36*, 1907, 877; see Cent. f. Bakt., II Abt., *21*, 1908, 258.) Produces slime in sucrose solutions. Appears to be closely related to *Bacillus subtilis*.

Nitrosobacillus thermophilus Campbell. (Science, *75*, 1932, 23.) A thermophilic aerobic rod with swollen clavate sporangia; forms nitrites from ammonium salts. From surface layers of soil from North Carolina and Florida.

Semiclostridium commune, *S. citreum*, *S. flavum* and *S. rubrum* Maassen. (Arbt. a. d. biol. Abt. f. Land- u. Forstwirtsch. am kaiserl. Ges. Amt., *5*, 1907, 1.) Produce slime in sucrose solutions.

Genus II. **Clostridium** *Prazmowski.**

(Prazmowski, Untersuchungen über die Entwickelungsgeschichte und Fermentwirkung einiger Bacterien-Arten, Inaug. Diss., Leipzig, 1880, 23; *Vibrio* Müller, Vermium terrestrium et fluviatilum, *1*, 1773, 39; *Bacterium* Ehrenberg, Evertebrata, Berlin, 1828, (8?)**; *Metallacter* Perty, Zur Kenntniss kleinster Lebensformen, 1852, (180?); *Amylobacter* Trecul, Compt. rend. Acad. Sci., Paris, *61*, 1865, 435; *Bacillus* Cohn, Beitr. z. Biol. d. Pflanzen, *1*, Heft 2, 1872, 175; *Tyrothrix* Duclaux, Ann. Inst. Nat. Agron., *4*, 1882, (79?); *Pacinia* Trevisan, Atti della Accad. Fis.-Med.-Statist., Milano, Ser. 4, *3*, 1885, (83?); *Cornilia* Trevisan, I generi e le specie delle Batteriacee, Milano, 1889, 21; *Granulobacter* Beijerinck, Verhandl. d. k. Akad. v. Wetensch., Amsterdam, Tweedie Sect., Deel I, 1893, 4; *Bactridium*, *Paraplectrum*, *Diplectridium* and *Plectridium* Fischer, Jahrb. f. Wissensch. Botan., *27*, 1895, 139; *Granulobacillus* Schattenfroh and Grassberger, Cent. f. Bakt., II Abt., *5*, 1899, 702; *Streptobacillus* Rist and Khoury, Ann. Inst. Past., *16*, 1902, 70; *Botulobacillus*, *Butyribacillus*, *Cellulobacillus*, *Putribacillus* and *Pectobacillus* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 342–343; *Pectinobacter* Makrinov, Arch. Sci. Biol. (Russ.), *18*, 1915, 442; *Bacteroides* Castellani and Chalmers, Man. of Trop. Med., 3rd ed., 1919, 959; *Butyriclostridium* and *Putriclostridium* Orla-Jensen, Jour. Bact., *6*, 1921, 263; *Rivoltillus* and *Metchnikovillus* Heller, Jour. Bact., *6*, 1921, 550; *Omelianskillus*, *Macintoshillus*, *Douglasillus*, *Henrillus*, *Flemingillus*, *Vallorillus*, *Multifermentans*, *Hiblerillus*, *Welchillus*, *Stoddardillus*, *Arloingillus*, *Meyerillus*, *Novillus*, *Seguinillus*, *Reglillus*, *Robertsonillus*, *Nicollaierillus*, *Martellillus*, *Recordillus*, *Tissierillus*, *Putrificus*, *Ermengemillus* and *Weinbergillus* Heller, Jour. Bact., *7*, 1922, 5–9; *Peptoclostridium* Donker, Inaug. Diss., Delft, 1926, 23; *Botulinus*, *Chauvoea* and *Welchia* Pribram, Jour. Bact., *18*, 1929, 374; *Anaerobacillus*, *Verrucosus* and *Euclostridium* Janke, Cent. f. Bakt., II Abt., *80*, 1930, 490; *Butylobacter* Bakonyi, U. S. Letters Pat., 1,818,782, 1931; *Caduceus*, *Endosporus*, *Inflabilis*, *Palmula* and *Terminosporus* Prévot, Ann. Inst. Past., *61*, 1938, 76–86; *Acuformis* (syn. *Palmula*) Prévot, Man. d. Class., etc., 1940, 152.) From Greek, *clostridium*, a little spindle.

Rods, frequently enlarged at sporulation, producing clostridial or plectridial forms. The cells possess no catalase. Anaerobic or microaerophilic. Biochemically very active. Many species ferment carbohydrates producing various acids (frequently including butyric) and gas (CO_2, H_2 and sometimes CH_4). Others cause rapid putrefaction of proteins producing offensive odors. Commonly found in soil and in human or animal feces. Some species, while growing saprophytically on decomposing vegetable matter or on dead tissue within an animal host, form various toxic and lytic substances and are thereby pathogenic.

The type species is *Clostridium butyricum* Prazmowski.

Key to the species of genus **Clostridium.**

I. Strictly anaerobic.
  A. Not typically fermenters of cellulose.
    1. Do not characteristically produce distinctive pigments.
      a. Spores central, excentric, to subterminal.
        b. Spores oval.

---

* Revised by Prof. R. S. Spray, School of Medicine, West Virginia University, Morgantown, West Virginia, November, 1938; further revision May, 1942.

** In a few instances the original records were inaccessible. In such cases the page is indicated as (8?). In all other cases the page indicates what is believed to be the earliest record of the designation cited.

c. Rods distinctly swollen at sporulation.
d. Motile.
e. Gelatin, or glucose gelatin, not liquefied.
f. Glucose fermented.
g. Coagulated albumin not liquefied.
h. Stormy fermentation, or at least active coagulation of milk. Also see hhh.
i. Glycerol not fermented.
j. Mannitol fermented.
k. Starch, lactose and sucrose fermented.
1. *Clostridium butyricum.*
kk. Starch not fermented. Lactose and sucrose fermented.
1a. *Clostridium beijerinckii.*
jj. Mannitol not fermented.
k. Starch and lactose not fermented.
1b. *Clostridium pasteurianum.*
ii. Glycerol fermented.
j. Mannitol not fermented.
k. Starch, lactose, sucrose and salicin fermented.
1c. *Clostridium multifermentans.*
hh. Milk slowly coagulated; not stormily. Also see hhh.
i. Glycerol and mannitol not fermented.
2. *Clostridium fallax.*
ii. Glycerol not recorded.
j. Acid, but no gas, from lactose and sucrose.
3. *Clostridium fissum.*
hhh. Milk not coagulated.
i. Glycerol not fermented.
4. *Clostridium difficile.*
gg. Coagulated albumin not recorded.
h. Milk acidified, but not coagulated.
5. *Clostridium viscifaciens.*
ee. Gelatin, or glucose gelatin, liquefied.
f. Glucose fermented.
g. Coagulated albumin not liquefied.
h. Milk slowly coagulated. Clot not digested.
i. Glycerol and mannitol not fermented.
j. Lactose fermented.
k. Sucrose not fermented. Salicin fermented.
6. *Clostridium septicum.*
kk. Sucrose fermented. Salicin not fermented.
7. *Clostridium feseri.*
ii. Glycerol fermented.
8. *Clostridium hemolyticum.*
hh. Milk acidified but not coagulated.
i. Glycerol fermented.
j. Mannitol not fermented.
k. Starch fermented. Lactose, sucrose and salicin

not fermented. Exotoxin formed; toxic on injection but not on feeding.

9. *Clostridium novyi.*

kk. Starch not recorded.

l. Lactose, sucrose and salicin not fermented.

m. Adonitol fermented.

10. *Clostridium botulinum.*

mm. Adonitol not fermented.

10a. *Clostridium botulinum.* Type C.

gg. Coagulated albumin slowly to rapidly liquefied.

h. Stormy fermentation, or at least active coagulation of milk. Clot not digested.

11. *Clostridium acetobutylicum.*

hh. Milk slowly and softly coagulated; not stormily. Clot slowly to rapidly digested.

i. Glycerol and mannitol not fermented. Also see iii.

j. Starch not recorded.

k. Lactose fermented.

12. *Clostridium aerofoetidum.*

kk. Lactose not fermented.

13. *Clostridium sporogenes.*

13a. *Clostridium sporogenes* var. *A. P. Marie.*

13b. *Clostridium sporogenes* var. *equine.*

13c. *Clostridium tyrosinogenes.*

13d. *Clostridium flabelliferum.*

13e. *Clostridium parasporogenes.*

ii. Glycerol fermented. Also see iii.

j. Mannitol not fermented.

14. *Clostridium parabotulinum* Types A and B.

iii. Glycerol not recorded.

j. Mannitol and starch not recorded.

k. Lactose and sucrose weakly fermented.

l. Gas formed from carbohydrates.

15. *Clostridium saccharolyticum.*

ll. Gas not formed from carbohydrates.

16. *Clostridium regulare.*

ff. Glucose not fermented. (Carbohydrates not fermented.)

g. Coagulated albumin not digested. Lab-coagulation of milk; increasing alkalinity. Clot digested.

17. *Clostridium hastiforme.*

gg. Coagulated albumin not recorded. Slow, mildly acid coagulation of milk. Clot digested.

18. *Clostridium subterminale.*

dd. Non-motile.

e. Gelatin, or glucose gelatin, not liquefied.

19. *Clostridium malenominatum.*

cc. Rods not swollen at sporulation.

d. Motile.
e. Gelatin, or glucose gelatin, liquefied.
f. Glucose fermented.
g. Coagulated albumin liquefied. Milk slowly coagulated. Clot slowly digested.
20. *Clostridium bifermentans.*
gg. Coagulated albumin not recorded.
h. Milk slowly coagulated; slimy.
i. Gas formed from glucose.
21. *Clostridium mucosum.*
ii. Acid but no gas from glucose.
22. *Clostridium pruchii.*
ee. Iron-gelatin (Spray), no growth.
23. *Clostridium cylindrosporum.*

dd. Non-motile.
e. Gelatin, or glucose gelatin, liquefied.
f. Glucose fermented.
g. Coagulated albumin not liquefied.
h. Milk stormily fermented. Clot not digested.
i. Glycerol fermentation variable.
j. Mannitol not fermented. Starch, lactose and sucrose fermented. Salicin rarely fermented. Types identified by specific toxin-antitoxin neutralization.
24. *Clostridium perfringens* Types A, B, C and D.

bb. Spores spherical.
c. Rods distinctly swollen at sporulation.
d. Motile.
e. Gelatin, or glucose gelatin, not liquefied.
f. Glucose fermented.
g. Coagulated albumin not liquefied.
h. Milk acidified; slowly and softly coagulated; not stormily. Clot not digested.
25. *Clostridium sphenoides.*
hh. Milk acidified but not coagulated.
26. *Clostridium innominatum.*

cc. Rods not swollen at sporulation.
d. Non-motile.
e. Gelatin, or glucose gelatin, not liquefied.
f. Glucose fermented.
g. Coagulated albumin not liquefied.
h. Milk acidified but not coagulated.
27. *Clostridium filiforme.*

aa. Spores terminal.
b. Spores distinctly oval to ellipsoid.
c. Rods distinctly swollen at sporulation.
d. Motile.
e. Gelatin, or glucose gelatin, not liquefied. Also see eee.
f. Glucose fermented.

g. Coagulated albumin not liquefied.
h. Milk slowly coagulated. Clot not digested.
i. Glycerol not fermented.
j. Mannitol fermented.
28. *Clostridium sartagoformum.*
jj. Mannitol not fermented.
29. *Clostridium paraputrificum.*
ff. Glucose not fermented.
g. Coagulated albumin not liquefied. Milk unchanged.
30. *Clostridium cochlearium.*
gg. Coagulated albumin not recorded.
h. Milk, or iron-milk (Spray), no growth.
i. Carbohydrates not fermented.
j. Ethyl alcohol fermented chiefly to caproic acid.
31. *Clostridium kluyverii.*
jj. Ethyl alcohol not fermented to caproic acid.
32. *Clostridium acidiurici.*
ee. Gelatin, or glucose gelatin, liquefied. Also see eee.
f. Glucose fermented.
g. Coagulated albumin liquefied.
h. Milk often, but not always, coagulated. Clot, if formed, not digested.
33. *Clostridium capitovale.*
hh. Milk acidified but not coagulated. Slow peptonization.
i. Glycerol and mannitol not recorded.
j. Starch not fermented.
34. *Clostridium parabifermentans.*
jj. Starch not recorded. Lactose weakly fermented.
35. *Clostridium ovalare.*
eee. Gelatin, or glucose gelatin, not recorded. Glucose fermented with acid but no gas.
36. *Clostridium zoogleicum.*
bb. Spores spherical, or nearly so.
c. Rods distinctly swollen at sporulation.
d. Motile.
e. Gelatin, or glucose gelatin, not liquefied. Also see eee.
f. Glucose fermented.
g. Coagulated albumin not liquefied.
h. Milk slowly coagulated, not stormily. Clot not digested. Also see hhh.
37. *Clostridium thermosaccharolyticum.*
hh. Milk not coagulated; unchanged. Also see hhh.
38. *Clostridium caloritolerans.*
hhh. Milk slowly alkalinized; casein slowly separated.
39. *Clostridium tetanoides.*
ee. Gelatin, or glucose gelatin, liquefied. Also see eee.
f. Glucose not fermented.

g. Coagulated albumin slowly liquefied.
h. Milk may show soft lab-coagulation. Clot not definitely digested.
40. *Clostridium tetani.*
hh. Milk shows slow, soft lab-coagulation. Clot slowly digested.
41. *Clostridium lentoputrescens.*
ff. Glucose weakly fermented.
g. Coagulated albumin slowly liquefied.
h. Milk variably coagulated. Clot, if formed, variably digested.
42. *Clostridium filamentosum.*
eee. Gelatin records at variance.
f. Glucose fermented.
g. Coagulated albumin not liquefied.
h. Milk not coagulated; unchanged.
43. *Clostridium tetanomorphum.*
dd. Non-motile.
e. Gelatin, or glucose gelatin, not liquefied.
f. Glucose fermented.
g. Coagulated albumin not recorded.
44. *Clostridium alcaligenes.*
ee. Gelatin, or glucose gelatin, liquefied.
f. Glucose fermented.
g. Coagulated albumin not liquefied.
45. *Clostridium angulosum.*
gg. Coagulated albumin liquefied.
46. *Clostridium putrefaciens.*
2. Characteristically produce pigments of varied colors.
a. Spores central, excentric, to subterminal.
b. Spores oval.
c. Rods distinctly swollen at sporulation.
d. Motile.
e. Gelatin, or glucose gelatin, not liquefied.
f. Black pigment formed around colonies in deep agar.
47. *Clostridium nigrificans.*
ff. Violet pigment formed in potato mash.
g. Indole is formed.
48. *Clostridium belfantii.*
gg. Indole is not formed.
48a. *Clostridium maggiorai.*
fff. Green pigment formed on potato slant.
g. Indole is formed.
48b. *Clostridium derossii.*
48c. *Clostridium ottolenghii.*
48d. *Clostridium paglianii.*
gg. Indole is not formed.
48e. *Clostridium lustigii.*
48f. *Clostridium sciavoi.*

ffff. Red pigment formed in potato mash.
g. Indole not recorded.
49. *Clostridium venturelli.*
ee. Gelatin, or glucose gelatin, liquefied.
f. Red to orange-red pigment formed, especially in starchy media.
g. Indole is not formed.
h. Stormy fermentation of milk. Clot slowly softened.
50. *Clostridium roseum.*
hh. Slow, spongy coagulation of milk. Clot slowly digested.
51. *Clostridium chromogenes.*
ff. Yellow-orange pigment formed in various media.
g. Indole is not formed.
h. Milk actively coagulated, not stormily. Clot is not digested.
52. *Clostridium felsineum.*
aa. Spores terminal.
b. Spores oval.
c. Rods distinctly swollen at sporulation.
d. Non-motile.
e. Gelatin, or glucose getamin, no liquefied.
f. Deep red pigment formed on potato slants.
53. *Clostridium carbonei.*
B. Typical fermenters of cellulose.
1. Do not characteristically produce distinctive pigments.
a. Spores terminal.
b. Spores distinctly oval to ellipsoid.
c. Rods distinctly swollen at sporulation.
d. Motile.
e. Gelatin, or glucose gelatin, liquefied. Ferments a variety of carbohydrates, other than cellulose, after prolonged cultivation.
54. *Clostridium spumarum.*
ee. Gelatin, or glucose gelatin, not recorded. Carbohydrates, other than cellulose, not fermented.
55. *Clostridium werneri.*
bb. Spores spherical, or nearly so.
c. Rods distinctly swollen at sporulation.
d. Non-motile.
56. *Clostridium cellulosolvens.*
2. Characteristic pigments produced in certain media.
a. Spores terminal.
b. Spores distinctly oval to ellipsoid. Rods distinctly swollen at sporulation.
57. *Clostridium dissolvens.*
bb. Spores spherical, or nearly so. Rods distinctly swollen at sporulation.
58. *Clostridium omelianskii.*

II. Microaerophilic. Grow customarily as anaerobes, but are able to produce scan sometimes atypical, growth on aerobic agar slants.

A. Not typically fermenters of cellulose.

1. Do not characteristically produce distinctive pigments.

a. Spores central, excentric, to subterminal. Spores oval. Rods distinctly swollen at sporulation.

59. *Clostridium carnis.*

ee. Gelatin, or glucose gelatin, liquefied.

f. Carbohydrates not fermented.

60. *Clostridium histolyticum.*

aa. Spores terminal. Spores distinctly oval to ellipsoid. Rods distinctly swollen at sporulation.

61. *Clostridium tertium.*

1. **Clostridium butyricum** Prazmowski. (Untersuch. ü. d. Entwickelungsgeschischte ü. Fermentwirk. einiger Bacterien-Arten, Inaug. Diss., Leipzig, 1880, 23; *Bacillus butyricus* Flügge, Die Mikroorg., 2 Aufl., 1886, 296.) From M. L., *acidum butyricum*, butyric acid.

Described from the original incomplete records of Prazmowski, as amplified by the studies of Adamson, Jour. Path. and Bact., *22*, 1919, 371, and of Hall, Jour. Inf. Dis., *30*, 1922, 467.

Rods: 0.7 by 5.0 to 7.0 microns, straight or slightly curved, with rounded ends, occurring singly, in pairs, in short chains and occasional long filaments. Motile. Spores oval, excentric to subterminal, swelling rods to clostridial forms. Gram-positive, becoming Gram-negative.

Granulose positive in clostridial stage (blue color with iodine).

Gelatin and glucose gelatin: Not liquefied.

Plain agar slant (anaerobic): Little or no growth.

Glucose agar surface colonies (anaerobic): Circular or slightly irregular, slightly raised, moist, creamy-white.

Deep glucose agar colonies: Biconvex, dense, yellowish-white, entire. Agar fragmented early by abundant gas.

Blood agar not hemolyzed.

Plain broth: Little or no growth.

Glucose broth: Abundant, diffuse turbidity; much gas.

Litmus milk: Acid and early coagulation. Litmus is reduced. Stormy fermentation; clot fragmented but not digested.

Indole not formed.

Nitrites not produced from nitrates.

Fixes atmospheric nitrogen.

Acid and gas from xylose, glucose, lactose, sucrose, starch, salicin, esculin and mannitol. Amygdalin, pectin, cellulose, glycerol and Ca-lactate not fermented.

Fermentation products include butyl, ethyl and iso-propyl alcohols, acetone, organic acids, H_2 and CO_2.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Non-pathogenic for guinea pig and rabbit.

Grows well from 30°C to 37°C.

Anaerobic.

Source: Originally isolated from cheese. Commonly encountered in naturally soured milk, in naturally fermented starchy plant substances and in soil.

Habitat: Probably rather widely dispersed in soils rich in humus.

NOTE: Many butyric acid-producing anaerobes are recorded in the literature. The questionable purity and the incomplete descriptions, particularly of the older species, make it difficult to determine the degree of relationship of these species to *Clostridium butyricum* Prazmowski. The following list cites the outstanding historic or recently described species.

Ferment butyrique, Pasteur, Compt. rend. Acad. Sci., Paris, *52*, 1861, 345 (Vibrion butyrique, Pasteur, *ibid.*, 1261); *Bacillus amylobacter* van Tieghem, Bull. de la Soc. Botan. de France, *24*, 1877, 128 (*Metallacter amylobacter* Trevisan, Reale Ist. Lombardo d. Sci. e Lett., Rendiconti, 1879, 147; *Clostridium amylobacter* Holland, Jour. Bact., *5*, 1920, 217); *Bacterium navicula* Reinke and Berthold, Untersuch. a. d. Bot. Lab. d. Univ. Göttingen, *1*, 1879, 21 (*Amylobacter navicula* Wehmer, Cent. f. Bakt., II Abt., *4*, 1898, 696; *Bacillus navicula* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *10*, 1898, 128; *Clostridium naviculum* Prévot, Ann. Inst. Past., *61*, 1938, 80); *Bacillus butylicus* Fitz, Ber. d. Deuts. Chem. Gesellsch., *15*, 1882, 867 (*Bacterium fitz* Buchner, Ztschr. f. Physiol. Chem., *9*, 1885, 384); Butylbacillus, Buchner, *ibid.*, 391; *Clostridium butyricum* (*Bacillus amylobacter*) *I*, *II*, *III*, Gruber, Cent. f. Bakt., *1*, 1887, 370–371; *Bacillus butylicus* Migula, Syst. d. Bakt., *2*, 1900, 598 (*Clostridium butyricum I*, Gruber, Cent. f. Bakt., *1*, 1887, 370); *Bacillus gruberi* Migula, *loc. cit.*, 599 (*Clostridium butyricum II*, Gruber, *loc. cit.*, 371); *Bacillus subanaerobius* Migula, *loc. cit.*, 600 (*Clostridium butyricum III*, Gruber, *loc. cit.*, 371); Bacille amylozyme, also bacille amylocyme, Perdrix, Ann. Inst. Past., *5*, 1891, 290 (*Bacillus amylozyma* Migula, Syst. d. Bakt., *2*, 1900, 626; *Bacillus amylozymicus* Peterson, Scott and Thompson, Biochem. Ztschr., *219*, 1930, 1; *Clostridium amylozyme* Prévot, Ann. Inst. Past., *61*, 1938, 79; *Clostridium* var. *amylozyme* Prévot, Man. d. Class., etc., 1940, 109); *Bacillus orthobutylicus* Grimbert, Ann. Inst. Past., *7*, 1893, 353; *Granulobacter butylicum* Beijerinck, Verhandl. d. K. Akad. v. Wetensch., Amsterdam, Tweedie Sectie, Deel I, 1893, 3 (*Clostridium butylicum* Donker, Thesis, Delft, 1926, 149; *Amylobacter butylicum* van Beynum and Pette, Cent. f. Bakt., II Abt., *93*, 1935, 200; this species is probably identical with *Clostridium butyricum I* Gruber, Cent. f. Bakt., I Abt., *1*, 1887, 370); *Granulobacter saccharobutyricum* Beijerinck, *loc. cit.*, 3, also in Arch. Néerland. d. Sci. Exactes et Nat., *29*, 1896, 1 (commonly identified with *Bacillus butylicus* Fitz, Ber. d. Deuts. Chem. Gesellsch., *15*, 1882, 867; *Bacillus humosus* Migula, Syst. d. Bakt., *2*, 1900, 600; *Clostridium saccharobutyricum* Donker, Thesis, Delft, 1926, 147; *Amylobacter saccharobutyricus* van Beynum and Pette, Cent. f. Bakt., II Abt., *64*, 1925, 359; *Clostridium intermedium* Donker, Thesis, Delft, 1926, 147 (Strain No. 3, Donker, *ibid.*, 39); *Clostridium butyricum iodophilum*

Svartz, Jour. Inf. Dis., *47*, 1930, 138 (*Clostridium iodophilum* Prévot, Ann. Inst. Past., *61*, 1938, 80); *Granulobacter saccharobutyricus immobile nonliquefaciens* McCoy, Fred, Peterson and Hastings, Jour. Inf. Dis., *46*, 1930, 121; *Bacillus amylobacter S* and *W*, Wertheim, U. S. Letters Pat., 1,917,676, 1933; *Clostridium tyrobutyricum* van Beynum and Pette, Cent. f. Bakt., II Abt., *93*, 1935, 208; *Clostridium polyfermenticum*, *Clostridium saccharopetum*, *Clostridium saccharophilicum* and *Clostridium saccharopostulatum* Partansky and Henry, Jour. Bact., *30*, 1935, 564.

1a. *Clostridium beijerinckii* Donker. (Donker, Thesis, Delft, 1926, 145.) Named for M. W. Beijerinck, the Dutch bacteriologist.

Has the general characters of *Clostridium butyricum*.

Distinctive character: Non-fermentation of starch.

Acid and gas from glucose, lactose, sucrose, inulin, galactose, fructose and mannitol. Glycerol and starch not fermented.

Source: From soil and fermenting plant tissues.

Habitat: Apparently widely distributed in agricultural soils.

1b. *Clostridium pasteurianum* Winogradsky. (Winogradsky, Arch. Sci. Biol. (Russ.), *3*, 1895, 330; *Clostridium pastorianum* Winogradsky, Cent. f. Bakt., II Abt., *9*, 1902, 43; *Bacillus pasteurianus* Lehmann and Neumann, Bakt. Diag., 4th Aufl., *2*, 1907, 82; *Bacillus pastorianus* Lehmann and Neumann, *ibid.*, 462; not *Bacillus pastorianus* Macé, Traité Prat. d. Bact., 4th ed., 1901, 957; *Bacillus winogradskyi* Weinberg et al., Les Microbes Anaér., 1937, 645.) Named for Louis Pasteur, the French scientist.

Probably related species: Bodily, Univ. Colorado Studies, *26*, 1938, 30, records 5 new species isolated from 10 strains received labeled *C. pasteurianum*. These have been designated as *Bacillus dulcitofermentans*, *Bacillus rhamnoticus*, *Bacillus inulofugus*, *Bacillus nonpentosus* and *Bacillus azoticus*.

Has the general characters of *Clostridium butyricum*.

Distinctive characters: Prolonged retention of the spore within a peculiar brush-like spore-capsule, and the non-fermentation of starch. Assimilates free atmospheric nitrogen.

Distinguished from *Clostridium beijerinckii* by the non-fermentation of lactose and mannitol, and from *Clostridium butyricum* by the non-fermentation of starch.

Acid and gas from glucose, sucrose, inulin, galactose, fructose and dextrin. Glycerol, starch, lactose and mannitol not fermented.

Source: Originally isolated from soil.

Habitat: Not determined, but apparently of restricted and local distribution in soil.

1c. *Clostridium multifermentans* Bergey et al. (*Bacillus multifermentans tenalbus* Stoddard, Lancet, *1*, 1912, 12; *Multifermentans tenalbus* Heller, Jour. Bact., *7*, 1922, 6; Bergey et al., Manual, 1st ed., 1923, 324.) From Latin, *multus*, many, and *fermentans*, fermenting.

Has the general characters of *Clostridium butyricum*, and is probably only a variety.

Distinctive character: Blood agar colonies show a zone of hemolysis in 24 hours.

Nitrites are produced from nitrates.

Distinguished from *Clostridium butyricum* by the above characters and by the fermentation of glycerol and non-fermentation of mannitol.

Distinguished from *Clostridium beijerinckii* by the fermentation of starch and of glycerol.

Distinguished from *Clostridium pasteurianum* by fermentation of starch and of lactose.

Acid and gas from glucose, fructose, galactose, maltose, lactose, sucrose, raffinose, starch, salicin, inulin and glycerol. Mannitol and dulcitol not fermented.

Source: Originally isolated from human gaseous gangrene.

Habitat: Found in soil and milk. Widely distributed in nature.

2. **Clostridium fallax** (Weinberg and Seguin) Bergey et al. (Bacille A, Weinberg and Seguin, Compt. rend. Soc. Biol., Paris, *78*, 1915, 277; *Bacillus fallax* Weinberg and Seguin, *ibid.*, 686; not *Bacillus fallax* Ornstein, Ztschr. f. Hyg., *91*, 1920, 159; *Vallorillus fallax* Heller, Jour. Bact., *7*, 1922, 6; Bergey et al., Manual, 1st ed., 1923, 325.) From Latin, *fallax*, deceptive.

Rods: 0.6 by 1.2 to 5.0 microns, occurring singly or rarely in pairs. Motile with peritrichous flagella. Encapsulated in body fluids. Spores rarely observed, oval, excentric to subterminal, swelling rods. Gram-positive.

Gelatin not liquefied.

Glucose agar surface colonies (anaerobic): Circular, flat, with transparent, crenated margin.

Glucose agar deep colonies: Lenticular, bean-shaped, irregular, smooth.

Agar slant (anaerobic): Grayish film.

Broth: Poor growth; slight diffuse turbidity.

Glucose broth: Abundant turbidity and gas. Clearing by sedimentation.

Indole not formed (Duffett, Jour. Bact., *29*, 1935, 576).

Litmus milk: Acid, slowly coagulated. Litmus reduced. Clot channeled by gas, but not digested.

Acid and gas from glucose, galactose, fructose, maltose, lactose, sucrose, inulin, salicin and starch. Glycerol and mannitol not fermented. Records vary in regard to action on lactose, inulin and salicin.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Meat medium reddened; not blackened or digested.

Pathogenicity for guinea pig variable, and commonly lost in cultivation. Forms a weak exotoxin.

Optimum temperature not recorded; grows well at 37°C.

Anaerobic.

Source: From war wounds, appendicitis, and once from black-leg of sheep.

Habitat: Not determined, other than these sources.

3. **Clostridium fissum** (Debono) Bergey et al. (*Bacillus fissus* Debono, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 232; Bergey et al., Manual, 1st ed., 1923, 332.) From Latin, *fissum*, separated.

Rods: Variable in size, rounded or square ends, occurring singly, in pairs and in chains and filaments. Motile. Spores small, oval, subterminal, slightly swelling rods. Gram-positive.

Gelatin: Not liquefied.

Deep gelatin colonies at 22°C: Small, brownish, globular, opaque and entire.

Deep glucose agar colonies: Small, white, globular. Gas is formed. No pigment formed.

Broth: Uniformly turbid.

Milk: Acid, coagulated after 3 days.

Indole not formed.

Acid and gas from glucose. Acid only in lactose and sucrose.

Coagulated albumin not liquefied.

Grows at 22°C and 37°C.

Anaerobic.

Distinctive character: All cultures smell strongly of butyric acid.

Source: From human feces.

Habitat: Not determined, other than this source.

4. **Clostridium difficile** (Hall and O'Toole) Prévot. (*Bacillus difficilis* Hall and O'Toole, Amer. Jour. Dis. Child., *49*, 1935, 390; *Clostridium difficilis* Prévot, Ann. Inst. Past. *61*, 1938, 84.) From Latin, *difficilis*, difficult.

Rods: Heavy-bodied. Actively motile.

Spores elongate, subterminal slightly swelling rods. Gram-positive.

Gelatin: Not liquefied.

Blood agar surface colonies (anaerobic): Irregular, flat and non-hemolytic.

Deep agar colonies: Minute, flat, opaque disks, becoming lobate.

Milk: Poor growth. Gas formed in traces, but milk unchanged.

Acid and gas from glucose, fructose, mannitol, salicin and xylose. Traces of gas, but no acid, from galactose, maltose, sucrose, lactose, raffinose, inulin and glycerol.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium with iron is moderately blackened. Digestion not recorded.

Pathogenic for guinea pig and rabbit. Subcutaneous inoculation induces marked edema. Death may occur in from 1 to 9 days.

Toxicity: Glucose broth culture filtrates kill guinea pig and rabbit in 24 to 36 hours.

Grows well at 37°C.

Anaerobic.

Source: From feces of new-born infants.

Habitat: Not determined, other than this source.

5. **Clostridium viscifaciens** Sherman and Erb. (U. S. Pat., 2,017,572, 1935.) From Latin, *viscus*, birdlime, glue; *faciens*, making.

Rods: Vegetative cells 3 to 10 microns long; average about 6 microns. Motile. Spores oval, 1 by 2 microns, central to subterminal, sometimes swelling rods to club-like and spindle-shaped cells. Gram-negative.

Granulose reaction positive.

Gelatin: Not liquefied.

Plain agar slant (anaerobic): No growth.

Plain agar stab: No growth.

Liquid media: Tendency toward flocculent growth.

Milk: Acidified but not coagulated. Casein not digested.

Corn mash: Not fermented or digested.

Indole not formed.

Nitrites produced from nitrates.

Ammonia produced from peptone.

Acid, gas and alcohols produced from glucose and maltose.

Acid and gas from sucrose, lactose, dextrin, starch, glycerol, mannitol and salicin.

Calcium lactate: Not fermented.

Fermentation products include butyl alcohol (66 parts), iso-propyl alcohol (31 parts), and small amounts of acetone (3 parts).

Limiting reaction for growth: About pH 4.0 to about pH 8.0.

Optimum temperature 32°C to 36°C. Grows from 15°C to 42.5°C.

Anaerobic.

Distinctive character: In fermentable sugar broths it produces a copious flocculum.

Source: From soil and from grains and other plant materials in contact with soil.

Habitat: Apparently widely dispersed in agricultural soils.

6. **Clostridium septicum** (Macé) Ford.* (Vibrion septique, Pasteur and Joubert, Compt. rend. Acad. Sci., Paris, *85*, 1877, 113, and Bull. Acad. Med., 2° Ser., *6*, 1877, 794; *Vibrio pasteurii* Trevisan, Reale Ist. Lombardo d. Sci. e. Lett., Rendiconti, Ser. 2, *12*, 1879, 147; *Bacillus septicus* Macé, Traité Prat. d. Bact., 1st ed., 1888, 455; not *Bacillus septicus* Migula, Syst. d. Bakt., *2*, 1900, 646 (Unnamed aerobic bacillus, Babes, Sept. Proc. d. Kindesalters, Leipzig, 1889, 32; *Bacillus septicus ulceris gangraenosi*

* Note: In an editorial, Jour. Amer. Vet. Med. Assoc., *62*, 1922–23, 565, the name *Clostridium septicum* is ascribed to Winslow et al., Jour. Bact., 5, 1920, 191. Search fails to confirm the reference. Casual mention is not regarded as sufficient to establish priority. Hence, Ford is regarded as the author of this binomial.

Sternberg, Man. Bact., 1893, 472); not *Bacillus septicus* Klein, Micro-organisms and Disease, 1884, 78; *Cornilia pasteuri* Trevisan, I generi e le specie delle Batteriacee, 1889, 22; *Bacillus septicus gangrenae* Arloing, Leçons sur la tuberculose et certaines septicémies, Paris, 1892, 451; Vibriogene septique, Rosenthal, Compt. rend. Soc. Biol., Paris, *64*, 1908, 398; *Vibrio septique* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., 1914, 438; *Rivoltillus vibrion* Heller, Jour. Bact., *7*, 1922, 6; *Bacillus parasarkophysematos* Miessner, Cent. f. Bakt., I Abt., Orig., *89* (Bhft.), 1922, 126, and Deuts. Tierarztl. Wchnschr., *30*, 1922, 416 (*Bacillus parasarcophysematos* Zeissler, Cent. f. Bakt., I Abt., Orig., *89* (Bhft.), 1922, 119); *Vibrio septicus* Rottgardt, Deuts. Tierarztl. Wchnschr., *34*, 1926, 553; Ford, Textbook of Bact., 1927, 726; *Clostridium septicus* Scott, Cornell Vet., *18*, 1928, 259; *Clostridium septique* Topley and Wilson, Princ. of Bact. and Immunol., 1st ed., *2*, 1929, 1161.) From Greek, *septicus*, putrefactive, septic.

Probable synonym: Bacillus of Ghon and Sachs, Cent. f. Bakt., I Abt., Orig., *34*, 1903, 289.

Identical or closely related species: *Clostridium balaenae* Prévot, Ann. Inst. Past., *61*, 1938, 81 (Walfischseptikämie Bacillus, Nielsen, Cent. f. Bakt., *7*, 1890, 269; Bacille de la septicémie de la baleine, Christiansen, Compt. rend. Soc. Biol., Paris, *83*, 1920, 324; Walfischbazillus, Christiansen, Cent. f. Bakt., I Abt., Orig., *84*, 1920, 127); *Bacillus gastromycosis ovis* Kitt, Bakt. u. Path. Mikros., 2 Aufl., 1893, 239 (Bradsotbacillus, Nielsen, Monats. Prakt. Tierhlk., *8*, 1897, 59); *Bacillus tumefaciens* Wilson, Lancet, *196*, 1919, 657 (*Clostridium tumefaciens* Prévot, Ann. Inst. Past., *61*, 1938, 81); not *Bacillus tumefaciens* Israilsky, Cent. f. Bakt., II Abt., *67*, 1926, 236; *Bacillus seu Clostridium sarcophysematos bovis* Kitt, Bakterienkunde u. Path. Mikros., 2 Aufl., 1893, 232 (*Bacillus sarcophysematos* Kitt, *ibid.*, Index, X; not *Bacillus sarcophysematos* Zeissler, Cent. f. Bakt., I Abt., Orig., *89* (Bhft.), 1922, 119.) (See *Clostridium feseri.*)

Confused in the older literature with Koch's bacillus of malignant edema, Mitt. a. d. kais. Gesundhts., *1*, 1881, 54 (*Bacillus oedematis maligni* Zopf, Die Spaltpilze, 3 Aufl., 1885, 88; *Clostridium oedematis malignis* Fischer, Jahrb. f. Wissen. Bot., *27*, 1895, (146?); *Bacillus oedematis* Schroeter, in Cohn's Kryptogamen-Flora v. Schlesien, *3*, *1*, 1886, 163; *Clostridium edematis* Holland, Jour. Bact., *5*, 1920, 218; *Clostridium oedematis-maligni* Bergey et al., Manual, 1st ed., 1923, 325).

It is commonly believed at present that Koch's bacillus of malignant edema was a culture of *Clostridium septicum* contaminated with *Clostridium sporogenes* or some closely related organism.

Described from Weinberg and Seguin, La Gang. Gaz., Paris, 1918, 79, and from Hall, Jour. Inf. Dis., *30*, 1922, 486.

Rods: 0.6 to 0.8 by 3.0 to 8.0 microns, rounded ends, occurring singly, in pairs and in short chains in cultures; long chains and filaments commonly predominate in body exudates. Motile, with peritrichous flagella. Spores oval, excentric to subterminal, swelling rods. Gram-positive.

Gelatin: Liquefied, with gas bubbles.

Agar surface colonies (anaerobic): Small, transparent, of variable shape.

Blood agar surface colonies (anaerobic): Delicate, flat, leaf-like, irregular. Hemolytic.

Deep agar colonies: Variable; usually finely filamentous, cottony, spherical.

Broth: Slight, diffuse turbidity, with clearing.

Litmus milk: Litmus reduced; slow coagulation and moderate gas. Clot not digested.

Indole not formed.

Nitrites produced from nitrates.

Acid and gas from glucose, fructose, galactose, maltose, lactose and salicin. Sucrose, inulin, mannitol and glycerol not fermented (Hall, *loc. cit.*, 489).

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Meat medium reddened; not blackened or digested.

Pathogenic for guinea pig, rabbit, mouse and pigeon. Forms an exotoxin for which an antitoxin is prepared.

Optimum temperature about 37°C.

Anaerobic.

Source: Originally isolated from animals inoculated with soil; later from malignant edema of animals, and from human war wounds and from appendicitis.

Habitat: Animal intestine, and in manured soils.

7. **Clostridium feseri** Trevisan. (Beweglichen Bakterien, Feser, Ztschr. f. Prakt. Vet.-Wissensch., *4*, 1876, 19; Trevisan, Atti Accad. Fis.-Med.-Stat. di Milano, *3*, 1885, 116; *Bacterium chauvoei* Arloing, Cornevin and Thomas, Le charbon symptomatique du boeuf, Paris, 2nd ed., 1887, 82; *Bacillus chauvoei* De Toni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1004; *Bacillus chauvaei* Trevisan, I generi e le specie delle Batteriacee, 1889, 22; *Bacillus feseri* Kitt, Bacterienkunde, etc., 2 Aufl., 1893, 233; *Bacillus anthracis symptomatici* Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 245; *Bacillus carbonis* Migula, in Engler and Prantl, Die natür. Pflanzenfam., *1*, 1a, 1895, 26; *Butyribacillus chauvoei* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 342; *Bacillus gangraenae emphysematosae* Hutyra and Marek, Spez. Path. u. Ther. d. Haust., 3 Aufl., *1*, 1910, 39; *Bacillus chauvei* Holland, Jour. Bact., *5*, 1920, 217; *Clostridium chauvei* Holland, *ibid.*, 217; *Bacillus anthracis-symptomatici* Holland, *ibid.*, 217; *Clostridium anthracis-symptomatici* Holland, *ibid.*, 217; *Bacillus sarkophysematos* Miessner, Cent. f. Bakt., I Abt., Orig., *89* (Bhft.), 1922, 123 (*Bacillus sarcophysematos* Zeissler, *ibid.*, 119; not *Bacillus sarcophysematos* Kitt, Bakterienkunde, etc., 2 Aufl., 1893, Index, X); *Bacillus symptomaticus* Matouschek, Cent. f. Bakt., II Abt., *58*, 1923, 472; *Clostridium chauvoei* Scott, Jour. Inf. Dis., *38*, 1926, 262; *Clostridium chauvaei* Scott, Cornell Vet., *18*, 1928, 259.) Named for Feser, an early German bacteriologist.

Possible synonyms: Bacterio ocello cuneato, Rivolta, Giorn. di Anat., Fisiol. e Patol. d. Animali, Piso, *14*, 1882, 33; Bacillum cuneatum, Rivolta, *ibid.*, 67; Bacillum ocello-cuneatum, Rivolta, *ibid.*, 67; *Bacterium cuneatum* Rivolta, *ibid.*, 77; *Bacterium ocello cuneatum* Rivolta, *ibid.*, 78; *Bacillus sarcophysematosi* Peppler, Cent. f. Bakt., I Abt., *29*, 1901, 354.

Rods: 1.0 by 3.0 to 8.0 microns, occurring singly, in pairs and in short chains. Usually show a dark chromatic point near each end. Motile with peritrichous flagella. Spores oval, excentric to subterminal, swelling rods. Gram-positive.

Gelatin: Liquefied. Gas bubbles.

Agar surface colonies (anaerobic): Small, grayish, semi-opaque, filamentous.

Agar slant (anaerobic): Grayish, spreading growth.

Broth: Turbid, slightly peptolytic.

Litmus milk: Acid; slowly coagulated. Gas may be formed. Clot not digested.

Indole not formed (early studies record only a trace).

Acid and gas from glucose, fructose, galactose, maltose, lactose and sucrose. Inulin, salicin, mannitol, glycerol and dextrin not fermented (Hall, Jour. Inf. Dis., *30*, 1922, 486).

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Egg-meat medium: Small gas bubbles in 8 hours. Meat becomes pinkish and the liquid slightly turbid. No blackening or digestion.

Pathogenic for guinea pig, mouse and rabbit. Forms an exotoxin.

Optimum temperature 37°C. Can grow at 50°C.

Anaerobic.

Source: The cause of black leg, black quarter or symptomatic anthrax in cattle and other animals.

Habitat: Probably soil; especially where heavily manured.

8. **Clostridium hemolyticum** (Hall) Hauduroy et al. (*Clostridium hemolyticus bovis* Vawter and Records, Jour. Amer. Vet. Med. Assoc., *68* (N.S. *21*), 1925–26, 512; *Bacillus hemolyticus* Hall, Jour. Inf. Dis., *45*, 1929, 156; Hauduroy et al., Dict. d. Bact. Path., 1937, 125.) From Greek, *haemo*, blood; *lyticus*, dissolving.

Related species: *Clostridium hemolyticum* var. *sordelli* Hauduroy et al., *loc. cit.*, 126 (*Bacillus sp.* (?), Sordelli, Prado and Ferrari, Compt. rend. Soc. Biol., Paris, *106*, 1931, 142; Unnamed anaerobe of Matte, Inst. Biol. Soc. Nac. Agric., Chile, *2*A, 1921, (31?) (cited from Vawter and Records, *loc. cit.*, 172).

Rods: 1.0 to 1.3 by 3.0 to 5.6 microns, with rounded ends, occurring singly, in pairs and in short chains. Motile with long peritrichous flagella. Spores oval to elongate, subterminal, swelling rods. Gram-positive.

Gelatin: Liquefied.

Blood agar surface colonies (anaerobic): Light, diffuse growth. Blood hemolyzed.

Deep agar colonies: At first lenticular, becoming densely woolly masses with short peripheral filaments. Little or no gas formed.

Broth plus liver: Luxuriant diffuse turbidity, followed by agglutinative clearing. Moderate gas formed.

Milk: Acid and slow coagulation. Clot not digested.

Acid and gas from glucose, fructose, galactose and glycerol. Lactose, maltose, sucrose, raffinose, arabinose, xylose, inulin, salicin, mannitol and dulcitol not fermented. Subsequent studies show that pure galactose is not fermented (Records and Vawter, Nevada Agr. Exp. Sta., Bull. 173, 1945, 48 pp.).

Indole is formed.

Methyl red and Voges-Proskauer tests are negative.

Nitrites are not produced from nitrates.

Hydrogen sulfide is produced. The four characteristics given above are from Records and Vawter (*loc. cit.*, 30).

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Meat medium reddened, not blackened. No digestion.

Pathogenic and toxic for guinea pig and rabbit. Effect due to an unstable hemolytic toxin.

Grows well at 37°C.

Anaerobic.

Source: From blood and tissues of cattle dying of icterohemoglobinuria.

Habitat: Not determined. Thus far isolated only from animals.

9. **Clostridium novyi** (Migula) Bergey et al. (*Bacillus oedematis maligni No. II*, Novy, Ztschr. f. Hyg., *17*, 1894, 212; *Bacillus oedematis thermophilus* Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 242; *Bacillus novyi* Migula, Syst. d. Bakt., *2*, 1900, 872; *Bacterium oedematis thermophilus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 126; *Bacillus thermophilus* Chester, Man. Determ. Bact., 1901, 265; *Bacillus oedematiens* Weinberg and Seguin, Compt. rend. Soc. Biol., Paris, *78*, 1915, 507 (Bacille B, Weinberg and Seguin, *ibid.*, 177); *Novillus maligni* Heller, Jour. Bact., *7*, 1922, 7; *Clostridium oedematiens* Bergey et al., Manual, 1st ed., 1923, 326; Bergey et al., *idem; Clostridium thermophilum* Pribram, Jour. Bact., *22*, 1931, 430; *Clostridium novyi* Type A, Scott, Turner and Vawter, Proc., 12th Internat. Vet. Congr., *2*, 1934, 175.) Named for F. G. Novy, the American bacteriologist who first isolated this organism.

Related or possibly identical species: Neuen pathogenen anaeroben Bacillus, Kerry, Osterr. Ztschr. f. Wiss. Veterinärk., *5*, 1894, 228; *Bacterium nivosum* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., 1914, 344 (Bacille neigeux, Jungano, Compt. rend. Soc. Biol., Paris, *62*, 1907, 677; Bacillo nevoso, Jungano, Il Tommasi, *2*, 1907, (731?); Gasödembazillus, Aschoff, Deuts. med. Wchnschr., *42*, 1916, 512; *Bacillus bellonensis* Sacquépée,

Compt. rend. Soc. Biol., Paris, *80*, 1917, 850 (Bacille de l'oedème gazeux malin, Sacquépée, *ibid.*, *78*, 1915, 316; *Clostridium bellonensis* Prévot, Ann. Inst. Past., *61*, 1938, 81); *Bacillus gigas* Zeissler and Rassfeld, Arch. Wiss. u. Prakt. Tierhlk., *59*, 1929, 419 (*Clostridium novyi* Type B, Scott et al., *loc. cit.*, 175; *Clostridium gigas* Prévot, Ann. Inst. Past., *61*, 1938, 82); not *Bacillus gigas* Trevisan, Atti. d. Accad. Fis.-Med.-Stat., Milano, Ser. 4, *3*, 1885, 96; *Clostridium novyi* Type C, Scott et al., *loc. cit.*, 175 (non-pathogenic bacillus of osteomyelitis of buffalo, Kraneveld, Nederl. Ind. Bl. Diergeneesk., *42*, 1930, 564; *Clostridium bubalorum* Prévot, Ann. Inst. Past., *61*, 1938, 82; *Bacillus osteomyelitis bubalorum* Prévot, Man. d. Class., etc., 1940, 123).

Rods: 0.8 to 0.9 by 2.5 to 5.0 microns, occurring singly and in pairs, not in chains. Motile with peritrichous flagella. Spores large, oval, subterminal, swelling rods. Gram-positive.

Gelatin: Liquefied and blackened.

Agar surface colonies (anaerobic): Small, white, with darker center, filamentous.

Agar slant (anaerobic): Grayish, spreading growth.

Deep agar colonies: Compact, opaque, becoming filamentous with age.

Broth: Turbid, with flocculent sediment.

Litmus milk: Acid, not coagulated. Litmus reduced.

Acid and gas from glucose, fructose, maltose, xylose, starch and glycerol. Lactose, sucrose, mannitol, dulcitol, inulin and salicin not fermented (Hall, Jour. Inf. Dis., *30*, 1922, 491).

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Pathogenic for guinea pig, rabbit, mouse, rat and pigeon. Forms an exotoxin, toxic on injection but not on feeding growth.

Optimum temperature 35°C to 38°C.

Anaerobic.

Source: From a guinea pig inoculated with peptonized casein; later from gaseous gangrene.

Habitat: Probably occurs in manured soils.

10. **Clostridium botulinum** (Van Ermengem) Holland. (*Bacillus botulinus* Van Ermengem, Cent. f. Bakt., I Abt., *19*, 1896, 443, and Ztschr. f. Hyg., *26*, 1897, 48; Holland, Jour. Bact., *5*, 1920, 217; *Ermengemillus botulinus* Heller, Jour. Bact., *7*, 1922, 8.) From Latin, *botulus*, sausage; M.L., *botulinus*, relating to sausage.

Clostridium botulinum comprises a number of toxic species, conveniently divided by Bengtson, U. S. Public Health Serv., Hyg. Lab. Bull. 136, 1924, 33, and by Meyer and Gunnison, Jour. Inf. Dis., *45*, 1929, 96 and 108, and by Gunnison and Meyer, Jour. Inf. Dis., *45*, 1929, 130, into a non-ovolytic (*Clostridium botulinum*) and an ovolytic (*Clostridium parabotulinum*) group. Authorities are not yet in agreement on fermentations and on variant sub-types, and the present groupings are only tentative, and subject to revision. Meyer and Gunnison cite some 15 sub-types on the basis of toxicity, agglutination and fermentation.

The original Van Ermengem strain is not available, and his description is inadequate for classification purposes. Description follows Bengtson (*loc. cit.*) who used Lister Institute Strain No. 94 (Brit. Med. Res. Counc., Spec. Rept. Ser. No. 12, 1917, 29; *ibid.*, Spec. Rept. Ser. No. 39, 1919, 26) as a type culture.

Rods: 0.5 to 0.8 by 3.0 to 8.0 microns, with rounded ends, occurring singly, in pairs and in short to occasional long chains. Motile with peritrichous flagella. Spores oval, central, subterminal, to terminal at maturation, slightly swelling rods. Gram-positive.

Gelatin: Liquefied.

Deep liver agar colonies: Fluffy with dense center.

Liver agar surface colonies (anaerobic): No perceptible growth.

Broth: Scant or no growth.

Liver broth: Luxuriant turbidity, with considerable gas.

Milk: Slowly increasing acidity. No coagulation. No gas.

Acid and gas from glucose, fructose, maltose, dextrin, glycerol, adonitol and inositol. Galactose, sucrose, lactose, raffinose, inulin, dulcitol, mannitol, xylose, arabinose, rhamnose and salicin not fermented (Bengtson, *loc. cit.*, 22–25).

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Meat medium not blackened or digested.

Pathogenic for animals. Forms a powerful exotoxin which is neurotoxic both on injection and feeding. Toxin is neutralized by *Clostridium parabotulinum* Type B antitoxin.

Optimum temperature 20° to 30°C (Van Ermengem, Ztschr. f. Hyg., *26*, 1897, 42); 30°C (Van Ermengem, Arch. d. Pharmacodyn., *3*, 1897, 213 and 499; see Williams and Reed, Jour. Inf. Dis., *71*, 1942, 227). Starin (Jour. Inf. Dis., *38*, 1926, 103), growth usually earlier at 37°C. Toxin production probably best around 28°C.

Anaerobic.

Source: Unknown. Culture received through Reddish from Robertson as *Bacillus botulinus* No. 94, Strain A, Institute of Infectious Diseases at Berlin. Similar strains have been isolated from canned foods.

Habitat: Probably occurs in soil.

10a. *Clostridium botulinum* Type C. (Toxin producing anaerobe, Bengtson, U. S. Pub. Health Repts., *37*, 1922, 164 and 2252; *Bacillus botulinus* Type C, Bengtson, *ibid.*, 38, and U. S. Pub. Health Serv., Hyg. Lab. Bull. 136, 1924, 7; *Clostridium luciliae* Bergey et al., Manual, 1st ed., 1923, 336.) From Latin, *botulus*, sausage.

Probably identical variety: *Clostridium parabotulinum equi* Theiler and Robinson, Rev. Gén. de Med. Vet., *36*, 1927, 199 (*Clostridium botulinum* Type E, Topley and Wilson, Principles of Bact. and Immunol., 2nd ed., 1936, 688; *Bacillus (Clostridium) botulinum D*, Weinberg and Ginsbourg, Données Recentes sur les Microbes Anaér., Paris, 1927, 107, but shown to be a Type C by Robinson, Union S. Africa, 16th Ann. Rept., Dir. Vet. Serv. and Animal Indus., 1930, 126; not *Clostridium botulinum* Type D, Meyer and Gunnison, *vide infra*). From a rat carcass presumably responsible for botulism in mules in South Africa.

Related varieties: *Bacillus parabotulinus* Seddon, Jour. Comp. Path. and Therap., *35*, 1922, 155 and 275 (*Clostridium parabotulinum* Ford, Text-Book of Bact., 1927, 743, although this name was used earlier in the "group" sense by Bengtson, U. S. Pub. Health Serv., Hyg. Lab. Bull. 136, 1924, 32). First isolated from bones considered the source of "bulbar paralysis" of cattle in Australia.

Clostridium parabotulinus bovis Theiler et al., Union S. Africa, Dept. Agric., 11th and 12th Repts. of the Dir. Vet. Educ. and Res., Part II, 1927, 1202 (*Clostridium botulinum* Type D, Meyer and Gunnison, Proc. Soc. Expt. Biol. and Med., *26*, 1928–29, 88, also Jour. Inf. Dis., *45*, 1929, 106; not *Clostridium botulinum* Type D, Weinberg and Ginsbourg, *vide supra*). From "lamziekte" of cattle in South Africa.

Clostridium botulinum Type E, Gunnison, Cummings and Meyer, Proc. Soc. Expt. Biol. and Med., *35*, 1936, 278. An organism received by them from the Russian Ukraine; source of isolation not stated.

Clostridium botulinum Type C may be regarded as a variety of *Clostridium botulinum*, as it has morphologic and cultural characters very similar to those of the Van Ermengem strain. Only divergent or additional characters are recorded here.

Rods: 0.5 to 0.8 by 3.0 to 6.0 microns, commonly slightly curved.

Agar stab: Slight growth. No gas.

Deep liver agar colonies: Lenticular, becoming loosely fluffy. Gas is formed.

Deep glucose agar colonies: Fluffy, without central nucleus. Gas is not formed.

Agar surface growth (anaerobic): Very scant, thin.

Broth: Scant growth.

Milk: Slowly increasing acidity. No coagulation. No digestion.

Acid and gas from glucose, fructose, galactose, maltose, glycerol and inositol. Dextrin is weakly fermented. Sucrose, lactose, raffinose, inulin, adonitol, dulcitol, mannitol, xylose, arabinose, rhamnose and salicin not fermented.

Pathogenic for animals. Forms a powerful exotoxin which is neurotoxic both on injection and feeding. Toxin is neutralized by homologous (Type Cα) antitoxin, but not by *Bacillus parabotulinus* Seddon (Type Cβ) antitoxin, although Seddon-toxin is neutralized by Type Cα antitoxin (Pfenninger, Jour. Inf. Dis., *35*, 1924, 347).

Grows well at 37°C.

Anaerobic.

Source: Larvae of blue-bottle fly (*Lucilia caesar*). Produces limberneck in chickens.

Habitat: Not determined, other than this source.

11. **Clostridium acetobutylicum** McCoy, Fred, Peterson and Hastings. (McCoy et al., Jour. Inf. Dis., *39*, 1926, 483; *ibid.*, *46*, 1930, 118; *Clostridium aceto-butylicum* Legg, U. S. Pat., 1,668,814, 1928; *Clostridium acetonobutylicum* Prévot, Ann. Inst. Past., *61*, 1938, 80; *Clostridium acetobutyricum* Prévot, Man. d. Class., etc., 1940, 110.) From Latin, *acetum*, vinegar and *butylicus*, butylic, relating to butyl alcohol.

Synonyms: *Bacillus granulobacter pectinovorum* Speakman, Jour. Biol. Chem., *41*, 1920, 319; *Clostridium acetonigenum* Donker, Inaug. Diss., Delft., 1926, 144.

Rods: Vegetative cells 0.6 to 0.72 by 2.6 to 4.7 microns; clostridia 1.3 to 1.6 by 4.7 to 5.5 microns. Straight, with rounded ends, occurring singly and in pairs, not in chains. No capsules. Motile with peritrichous flagella. Spores oval, excentric to subterminal, swelling rods to clostridia. Gram-positive, becoming Gram-negative.

Granulose reaction positive in clostridial stage.

Glucose gelatin: Liquefied.

Glucose agar surface colonies (anaerobic): Compact, raised, fairly regular.

Deep glucose agar colonies: Compact, typically lenticular and smooth. Agar fragmented early by abundant gas.

Blood agar not hemolyzed.

Pigmentation: None; colonies creamy-white, opaque.

Plain broth: No growth.

Glucose broth: Abundant, uniform turbidity, with much gas.

Litmus milk: Acid and active, often stormy, coagulation. Litmus reduced. Clot fragmented by gas, but not visibly digested. Proteolysis demonstrable, however, on milk agar.

Potato: Growth creamy-yellow. Potato digested to a yellow slime.

Corn mash: Much gas with butylic odor.

Indole not formed.

Acetylmethylcarbinol formed from many carbohydrates.

Nitrites not produced from nitrates.

Nitrites reduced to ammonia.

Acid and gas from arabinose, xylose, rhamnose, glucose, galactose, mannose, fructose, sucrose, maltose, lactose, raffinose, melezitose, starch, dextrin, inulin, glycogen, *d*-mannitol, α-methyl glucoside and salicin. Esculin, amygdalin and trehalose are weakly fermented. Melobiose, dulcitol, *d*-arabitol, perseitol, lactositol, sorbitol, erythritol, adonitol, inositol, quercitol, glycerol, pectin and cellulose are not fermented.

Fermentation products include acetone, butyl and ethyl alcohols, butyric and acetic acids, H_2 and CO_2.

Coagulated albumin cubes: Softened and browned by slow digestion.

Hydrogen sulfide produced from thiosulfate or sulfite; generally negative from proteinaceous sources.

Blood serum not liquefied.

Brain medium not blackened or digested.

Non-pathogenic for guinea pig and rabbit.

Optimum temperature probably about 37°C. Grows from 20°C to 47°C.

Anaerobic.

Source: From corn, molasses, potato and garden soil.

Habitat: Widely, but apparently sparsely, dispersed in agricultural soils.

NOTE: A number of acetone and butyl alcohol-fermenting anaerobes have been described. Present knowledge, however, does not permit any expression of the degree of possible relationship. Only a few well-described species are cited. *Bacillus butylicus B. F.*, Ricard, U. S. Pat., 1,385,888, 1921; *Bacillus butylaceticum* Freiberg, U. S. Pat., 1,537,597, 1925; *Clostridium butyricum* (*Prazmowski-Pike-Smyth*) Pike and Smyth, U. S. Pat., 1,655,435, 1928; *Butylobacter betae*, *Butylobacter sinense*, *Butylobacter solani* and *Butylobacter zeae* Bakonyi, British Pat., 328,723, 1930, and U. S. Pat., 1,818,-782, 1931; *Bacillus saccharobutyricus liquefaciens* McCoy et al., Jour. Inf. Dis., *46*, 1930, 121 (*Bacillus saccharobutyricum liquefaciens* Legg and Stiles, U. S. Pat., 1,927,813, 1933); *Clostridium saccharobutylicum-gamma* Izsak and Funk, U. S. Pat., 1,908,361, 1933 (*Clostridium saccharobutylicum gamma* and *Clostridium saccharobutyricum gamma* Izsak and Funk, U. S. Pat., 2,016,112, 1935); *Clostridium saccharo-acetobutylicum-alpha* McCoy, British Pat., 415,311, 1934; *Clostridium propyl-butylicum* Muller and Legg, British Pat., 415,312, 1934 (*Clostridium propyl butylicum* Legg and Stiles, U. S. Pat., 2,063,448, 1936); *Clostridium saccharobutyl-acetonicum* Loughlin, British Pat., 409,730, 1934, and U. S. Pat., 1,996,428, 1935, and 1,992,921, 1935; *Clostridium saccharo-acetobutylicum* Stiles and Legg, British Pat., 437,121, 1935 (*Clostridium saccharo-acetobutylicum* Legg, U. S. Pat., 2,063,449, 1936); *Clostridium saccharo-acetobutylicum-beta* Arzberger, U. S. Pat., 2,050,219, 1936; *Clostridium saccharo-acetobutylicum-gamma* Arzberger, *ibid.*; *Clostridium inverto-acetobutylicum* Legg and Stiles, British Pat., 437,120, 1935, and Legg, U. S. Pat., 2,063,449, 1936; *Clostridium* (*Bacillus*) *tetrylium* Owen, Mobley and Arroyo, Cent. f. Bakt., II Abt., *95*, 1936, 131; *Clostridium saccharobutyl-isopropyl-acetonicum* Loughlin, U. S. Pat., 2,085,666, 1937 (*Clostridium saccharo-butyl-isopropyl-acetonicum* Loughlin, *ibid.*, and U. S. Pat., 2,096,377, 1937).

12. **Clostridium aerofoetidum** (Weinberg and Seguin) Bergey et al. (Bacille D, Weinberg, Compt. rend. Soc. Biol., Paris, *79*, 1916, 117; *Bacillus aerofoetidus* Weinberg and Seguin, *ibid.*, 1028; *Bacillus aero-foetidus* McIntosh, Med. Res. Counc., Spec. Rept. Ser. No. 39, 1919, 42; *Seguinillus aerofoetidus* Heller, Jour. Bact., 7, 1922, 7; Bergey et al., Manual, 1st ed., 1923, 327.) From Latin, *aer*, air and *foetidus*, fetid.

Rods: 0.4 to 0.6 by 3.0 to 5.0 microns, occurring singly, in pairs and in short chains. Motile with peritrichous flagella. Spores rare, oval, subterminal, slightly swelling rods. Gram-positive.

Gelatin: Rapidly liquefied.

Agar surface colonies (anaerobic): Circular, transparent, with faintly bluish tint, fimbriate.

Deep agar colonies: Lenticular, becoming indented and lobate.

Blood agar not hemolyzed.

Glucose broth: Turbid; with sediment.

Litmus milk: Acid; slowly coagulated; followed by slow peptonization. Gas is formed.

Acid and gas from glucose, fructose, galactose, mannose, maltose, lactose, xylose, amygdalin, salicin, esculin and glycogen. Sucrose, inulin, glycerol and mannitol not fermented.

Coagulated albumin slowly liquefied.

Blood serum is liquefied.

Brain medium blackened and digested.

Meat medium reddened, then blackened and slowly digested.

Slightly pathogenic for guinea pig.

Optimum temperature 30°C to 35°C.

Anaerobic.

Source: From gaseous gangrene and from feces.

Habitat: Not determined other than these sources. Probably occurs in soil.

13. **Clostridium sporogenes** (Metchnikoff) Bergey et al. (*Bacillus sporogenes* var. *A*, Metchnikoff, Ann. Inst. Past., *22*, 1908, 944; Bergey et al., Manual, 1st ed., 1923, 329; not *Clostridium sporogenes* Holland, Jour. Bact., *5*, 1920, 220 (*Bacillus enteritidis sporogenes* Klein, Cent. f. Bakt., I Abt., *18*, 1895, 737; *Bacillus sporogenes* Migula, Syst. d. Bakt., *2*, 1900, 560; *Bacillus (enteritidis) sporogenes* and *Bacillus enteritidis* Klein, Local Govt. Bd., Ann. Rept. Med. Off., London, *33*, 1903–04, 442 and 443.) From Greek, *sporus*, seed; M.L., spore; *genes*, producing.

Two varieties, *A* and *B*, were described. *Bacillus sporogenes* var. *A*, Metchnikoff, *loc. cit.*, 944 (*Metchnikovillus sporogenes* Heller, Jour. Bact., *7*, 1922, 9; *Clostridium sporogenes* var. *A*, Prévot, Ann. Inst. Past., *61*, 1938, 83) is regarded as the typical form and is described here. Var. *B*, see *Clostridium bifermentans*.

Synonyms or probably related species: Oedembacillen, Koch, Mitt. a. d. kaiserl. Gesundheitsamte, *1*, 1881, 54; *Bacillus oedematis maligni* Zopf, Die Spaltpilze, 3 Aufl., 1885, 88 (not *Bacillus oedematis maligni* Liborius, Ztschr. f. Hyg., *1*, 1886, 158; *Bacillus oedematis* Migula, Syst. d. Bakt., *2*, 1900, 604); *Bacillus oedematis* Chester, Man. Determ. Bact., 1901, 292; *Clostridium oedematis maligni* Bergey et al., Manual 1st ed., 1923, 325 (see Species No. 6, *Clostridium septicum* Ford, p. 774): *Paraplectrum foetidum* Weigmann, Cent. f. Bakt., II Abt., *4*, 1898, 827 (Bacterie β, Weigmann, Cent. f. Bakt., II Abt., *2*, 1896, 155; *Bacillus weigmanni* Chester, Man. Determ. Bact., 1901, 300; *Plectridium foetidum* Weigmann, Mykologie der Milch, Leipzig, 1911, 70; *Bacillus anaerobius foetidus* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., 1914, 329; *Endosporus foetidus* Prévot, Ann. Inst. Past., *61*, 1938, 75); *Bacillus saprogenes carnis* Salus, Arch. f. Hyg., *51*, 1904, 114 (*Bacillus saprogenes* Salus, *ibid.*, 115; not *Bacillus saprogenes I, II, III*, Herfeldt, Cent. f. Bakt., II Abt., *1*, 1895, 77; *Bacillus carnis saprogenes* Salus, Arch. f. Hyg., *51*, 1904, 124; *Plectridium saprogenes* Prévot, Ann. Inst. Past., *61*, 1938, 87); *Bacillus sporogenes coagulans* Debono, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 229 (*Clostridium coagulans* Bergey et al., Manual, 1st ed., 1923, 335); Reading Bacillus, Donaldson and Joyce, Lancet, *2*, 1917, 448; *Bacillus putrificus verrucosus* Zeissler, Ztschr. f. Infkrnkh. u. Hyg. Haust., *21*, 1920–21, 13 (*Bacillus verrucosus* Lehmann and Süssmann, in Lehmann and Neumann, Bakt. Diag., 7 Aufl., *2*, 1927, 662).

Rods: 0.6 to 0.8 by 3.0 to 7.0 microns, with rounded ends, occurring singly, in pairs, or less frequently in short to long chains and filaments. Motile with peritrichous flagella. Spores oval, excentric to subterminal, swelling rods. Gram-positive.

Gelatin: Liquefied and blackened.

Agar surface colonies (anaerobic): Small, irregular, transparent, becoming opaque, yellowish-white, fimbriate.

Deep agar colonies: Woolly balls with dense, nodular center.

Agar slant (anaerobic): Grayish, opaque, spreading.

Blood agar is hemolyzed.

Broth: Turbid. Gas is formed. Putrid odor.

Litmus milk: Softly coagulated. Litmus reduced. Slow peptonization, leaving a dark, amber-colored liquid.

Indole formed (trace). Not formed (Hall, Jour. Inf. Dis., *30*, 1922, 482).

Nitrites not produced from nitrates.

Acid and gas from glucose, fructose,

galactose and maltose. Lactose, sucrose, salicin, glycerol, mannitol and inulin not fermented. (Records vary on many sugars.)

Coagulated albumin liquefied.

Blood serum liquefied to a dark, putrid liquid.

Brain medium blackened and digested. Foul odor.

Meat medium reddened, then blackened and digested with foul odor. Gas is produced. Tyrosin crystals not obvious.

Non-pathogenic to guinea pig and rabbit, other than a slight, temporary local tumefaction. Filtrate non-toxic on injection and feeding.

Optimum temperature 37°C. Can grow at 50°C.

Anaerobic.

Source: From intestinal contents, gaseous gangrene, and from soil.

Habitat: Common in soil, especially where heavily manured.

The following species are commonly regarded as variants of the typical *Clostridium sporogenes*.

13a. *Clostridium sporogenes* var. *A. P. Marie* Prévot, Ann. Inst. Past., *61*, 1938, 83 (Bacille anaérobie, Marie, Compt. rend. Soc. Biol., Paris, *93*, 1925, 21).

Resembles the typical *Clostridium sporogenes* except in the sharp but not putrid odor of its cultures.

Pathogenicity: Large abscesses are induced on subcutaneous injection into guinea pigs.

From spontaneous putrefaction of macerated pork.

13b. *Clostridium sporogenes* var. *equine* Prévot, Ann. Inst. Past., *61*, 1938, 83 (Unnamed anaerobe No. IV, Choukévitch, Ann. Inst. Past., *25*, 1911, 259).

Sporulation is delayed and restricted. Spores are long and almost rectilinear.

Litmus milk is coagulated, then the clot is digested after 3 to 4 weeks.

Coagulated albumin is slowly dissolved.

Not pathogenic for guinea pig or mouse.

From large intestine of horse.

13c. *Clostridium tyrosinogenes* (Hall) Bergey et al. (Culture No. 106, Hall and Finnerud, Proc. Soc. Expt. Biol. and Med., *19*, 1921–22, 48; *Bacillus tyrosinogenes* Hall, Abst. Bact., *6*, 1922, 7; not *Bacillus tyrosinogenes* Rusconi, as cited by Carbone, Ramazotti, Mazzucchi and Monti, Boll. Ist. Sieroter., Milan, *2*, 1921, (29?), see Clark and Smith, Jour. Bact., *37*, 1939, 278; Bergey et al., Manual, 1st ed., 1923, 329; *Clostridium sporogenes* var. *tyrosinogenes* Prévot, Ann. Inst. Past., *61*, 1938, 83.) From Greek, *tyrus*, cheese; M. L., *tyrosinum*, tyrosine; *genes*, producing.

Ferments monosaccharides but not higher carbohydrates (Hall, Jour. Inf. Dis., *30*, 1922, 482).

Traces of gas, but no acid, from glycerol, sorbitol, mannose, xylose, lactose, sucrose, arabinose, galactose, salicin, inulin, dextrin and starch (F. E. Clark, personal communication).

Distinctive character: Forms large amounts of tyrosin which precipitate in cultures in protein media.

Source: Originally isolated from a culture erroneously labeled *Bacillus tetani*. Later isolated from an amputated arm.

Habitat: Not determined. Only two isolations on record.

13d. *Clostridium flabelliferum* Sturges and Reddish. (Fish-tailed putrefactive anaerobe, Reddish and Sturges, Abst. Bact., *8*, 1924, 5; Sturges and Reddish, Jour. Bact., *11*, 1926, 37; *Clostridium sporogenes* var. *caudapiscis* Prévot, Ann. Inst. Past., *61*, 1938, 83.) From Latin, *flabellum*, a little fan; *fer*, bearing.

Glucose agar surface colonies (anaerobic): Coarse, raised, with long peripheral intertwining outgrowths.

Deep plain agar colonies: Irregular, becoming woolly.

Sucrose is fermented (in contrast with *Clostridium sporogenes*).

Distinctive character: Spores are long

retained within the sporangium, of which the distal end frays out to fibrils, giving the characteristic fish-tail appearance. Otherwise closely resembles *Clostridium sporogenes*.

Source: From soured hams and from salt.

Habitat: Not determined, other than these sources.

13e. *Clostridium parasporogenes* (Bulloch et al.) Bergey et al. (Bacillus Type XII, McIntosh and Fildes, Med. Res. Counc., Spec. Rept. Ser. No. 12, 1917, 36; *Bacillus parasporogenes* Bulloch et al., Med. Res. Counc., Spec. Rept. Ser. No. 39, 1919, 39; Bergey et al., Manual, 1st ed., 1923, 327; *Clostridium sporogenes* var. *parasporogenes* Prévot, Ann. Inst. Past., *61*, 1938, 83.)

Deep agar colonies: Lenticular to slightly irregular. Not woolly.

Pathogenic for young guinea pigs. Filtrate non-toxic on injection or on feeding.

Optimum temperature 30°C to 35°C.

Distinctive character: Resembles *Clostridium sporogenes*, but does not form woolly colonies in deep agar, and is agglutinatively distinct. Probably merely a variety.

Source: From gaseous gangrene.

Habitat: Not determined. Probably occurs in soil.

14. **Clostridium parabotulinum** Bengtson. (U. S. Pub. Health Serv., Hyg. Lab. Bull. 136, 1924, 32; Types A and B, Burke, Jour. Bact., *4*, 1919, 556; *Clostridium botulinum* Types A and B, Bergey et al., Manual, 1st ed., 1923, 328.) From Latin, *para*, like; M.L., *botulinum*, a species name.

Note: This group comprises the putrefactive (ovolytic) species, including strains commonly referred to as *Memphis* and *Canton* (Type A), and *Nevin* (Type B). Growth of these types is more easily obtained than with the *Clostridium botulinum* strains, and the reactions are more obvious.

Gunnison and Meyer (Jour. Inf. Dis., *45*, 1929, 130) propose an intermediate group between *Clostridium botulinum* and *Clostridium parabotulinum*, which they call *Clostridium metabotulinum*. Such a group would provisionally include certain European Type B strains, the Australian Type C, certain American Type C strains, and the South African Type D.

Rods: 0.5 to 0.8 by 3.0 by 8.0 microns, with rounded ends, occurring singly, in pairs, and in short chains. Motile with peritrichous flagella. Spores oval, subterminal, distinctly swelling rods. Gram-positive.

Gelatin: Liquefied.

Deep liver agar colonies: Type A tend to be restricted to compact disks, with sharp outline and small, opaque nucleus at periphery. Type B tend rather to form loose, woolly colonies (indicative only).

Liver agar surface growth (anaerobic): Profuse, moist.

Broth: Fairly abundant diffuse turbidity. Many strains spontaneously agglutinate.

Liver broth: Luxuriant turbidity. Profuse gas.

Milk: Slight acidity; slow curdling precipitation, with subsequent digestion and darkening.

Fermentation records are variable: Acid and gas from glucose, fructose, maltose, dextrin, glycerol and salicin. Galactose, sucrose, lactose, rhamnose, raffinose, inulin, adonitol, dulcitol, mannitol, xylose, arabinose and inositol not fermented (Bengtson, *loc. cit.*, 22–25).

Coagulated albumin liquefied: Action of Type B usually more marked than that of Type A.

Blood serum liquefied.

Brain medium blackened and digested, with putrefactive odor.

Meat medium blackened and digested. Putrefactive odor. Tyrosine crystals not observed.

Pathogenic for animals. Forms a powerful exotoxin which is neurotoxic both on injection and feeding, and which

is neutralized only by the homologous type antitoxin.

Optimum temperature: Records at variance. Grows best at 35 to 37°C. Toxin production best at about 28°C.

Anaerobic.

Distinctive character: Types are identified chiefly by protection tests with known-type antitoxin, and to less extent by agglutination.

Source: Chiefly from spoiled, non-acid canned goods, from soil and from silage.

Habitat: Found rather widely dispersed in soil.

15. **Clostridium saccharolyticum** Bergey et al. (*Bacillus sporogenes saccharolyticus* Distaso, Cent. f. Bakt., I Abt., Orig., *59*, 1911, 100; Bergey et al., Manual, 1st ed., 1923, 334.) From Greek, *saccharum*, sugar; *lyticus*, dissolving, digesting.

Rods: Short, rounded ends, occurring singly, in pairs and in short chains. Motile. Spores large, oval, excentric to subterminal, swelling rods. Gram-positive.

Gelatin: Liquefied.

Deep glucose agar colonies: Gray, biconvex, lenticular, granular, entire. Gas is formed.

Broth: Turbid.

Milk: Soft coagulation; casein precipitated, then peptonized, leaving a clear, yellow-amber supernatant fluid.

Indole is formed.

Acid and gas feebly formed from glucose. Lactose and sucrose feebly, or doubtfully, fermented.

Coagulated albumin slowly liquefied.

Grows well at 37°C.

Anaerobic.

Distinctive character: All cultures give a mixed butyric and fecal odor.

Source: From feces of a chimpanzee.

Habitat: Not determined, other than this source.

16. **Clostridium regulare** Bergey et al. (*Bacillus sporogenes regularis* Distaso, Cent. f. Bakt., I Abt., Orig., *59*, 1911, 100; Bergey et al., Manual, 1st ed., 1923, 334.) From Latin, straight.

Long rods: With rounded ends, occurring singly and in pairs. Motile. Spores oval, small, subterminal, slightly swelling rods. Gram-positive.

Gelatin: Liquefied.

Deep agar colonies: Small, opaque, irregular.

Milk: Acid; slowly coagulated, then clot slowly digested.

Indole formed in small quantity.

Slight acidity from glucose, lactose and sucrose. Gas is not formed. Odor of scatol and valerianic acid.

Coagulated albumin slowly liquefied.

Grows at 37°C.

Anaerobic.

Source: From human feces.

Habitat: Not determined, other than this source.

17. **Clostridium hastiforme** MacLennan. (A4, Cunningham, Cent. f. Bakt., II Abt., *82*, 1930–31, 487, and B4a, Cunningham, *ibid.*, *83*, 1931, 11; MacLennan, Jour. Path. and Bact., *49*, 1939, 543.) From Latin, resembling a spear.

Rods: Slender, 0.3 to 0.6 by 2.0 to 6.0 microns, with rounded ends, occurring singly, in pairs, and rarely in short chains. Filaments not observed. Motile, with delicate peritrichous flagella; motility persists even after sporulation. Spores ellipsoidal, subterminal, swelling rods. Polar-cap of protoplasm remains long attached to free spores. Gram-positive.

Gelatin: Rapidly liquefied. Blackening not recorded.

Plain agar surface colonies (anaerobic): Minute translucent dots, becoming irregularly round, granular, grayish-white, with opaque center and delicate translucent border.

Blood agar surface colonies (anaerobic): As above, but larger and more opaque. Old colonies show grayish pigmentation. No hemolysis.

Deep plain agar colonies: Small, irregularly round with coarsely filamentous

border. A little gas is occasionally formed.

Broth: Transient uniform turbidity, quickly settling as a heavy, white, flocculent deposit. Culture assumes a cheesy odor.

Milk: Abundant growth, with lab-coagulation in 2 to 3 days. No increase in acidity; becoming slightly alkaline. Clot completely digested in 10 to 14 days, leaving a white, semi-translucent fluid of cheesy odor.

Indole not formed.

Ammonia not formed.

Hydrogen sulfide not formed.

Glucose not fermented.

Carbohydrates not fermented.

Egg medium: No digestion or other visible change.

Coagulated albumin not digested or blackened.

Blood serum not digested or blackened.

Meat medium not digested or blackened, even in presence of metallic iron. Meat particles slightly reddened.

Brain medium not digested or blackened.

Grows well between 22°C and 37°C.

Anaerobic.

Non-pathogenic to guinea pigs on subcutaneous inoculation (Cunningham, Cent. f. Bakt., II Abt., *83*, 1931, 12).

Source: Originally isolated by Cunningham as a dissociant from a culture of *Bacillus saccharobutyricus* von Klecki. Later isolated by MacLennan; 1 strain from a culture of *Clostridium sporogenes*, and 2 strains from street dust.

Habitat: Not determined, other than these sources.

18. **Clostridium subterminale** (Hall and Whitehead) *comb. nov.* (*Bacillus subterminalis* Hall and Whitehead, Jour. Inf. Dis., *41*, 1927, 66.) Named from the characteristic position of the spores.

Rods: Occurring singly, in pairs and rarely in short chains. Motile. Spores oval, subterminal, swelling rods. Gram-positive.

Gelatin: Slowly liquefied, with slight turbidity and black sediment.

Blood agar surface colonies (anaerobic): Delicate. At first mildly, later actively, hemolytic.

Deep agar colonies: Opaque, compact, biconvex or lobate discs.

Agar slant (anaerobic): No surface growth.

Glucose broth: Turbidity, but no acid or gas formed.

Indole not formed.

Milk: Slowly coagulated (2 to 3 days), with mild acidity and gas. Slow but complete digestion of casein (8 to 18 days).

Glucose, fructose, galactose, maltose and lactose not fermented.

Brain medium: Slight turbidity in supernatant fluid. Slight gas formation and slow digestion.

Iron brain medium: Blackened in 2 to 3 days.

Tyrosin crystals not observable.

Non-pathogenic to guinea pigs on subcutaneous injection.

Grows well at 37°C.

Obligately anaerobic.

Source: From an African arrowhead.

Habitat: Not determined, other than this source.

19. **Clostridium malenominatum** (Weinberg et al.) *comb. nov.* (Pseudo-coli anaérobie, Jungano, Compt. rend. Soc. Biol., Paris, *65*, 1908–09, 457; *Bacillus pseudo-coli anaérobie* Jungano and Distaso, Les Anaérobies, 1910, 162; *Bacillus pseudocoli anaerobius* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., 1914, 345; *Bacillus malenominatus* Weinberg et al., Les Microbes Anaérobies, 1937, 763; *Paraplectrum malenominatum* Prévot, Ann. Inst. Past., *61*, 1938, 75.) From Latin, meaning badly named.

Rods: Short, cocco-bacillary, becoming elongated to short filaments in old cultures—especially in sugar broth. Ends rounded. Distinct bipolar staining tendency. Non-motile. Capsulated, especially in body fluids. Spores oval,

subterminal, slightly swelling rods. Gram-negative.

Gelatin: No growth.

Deep agar colonies: Small, round, very regular, almost transparent. Gas not formed.

Plain broth: Uniform turbidity, settling after 48 hours, forming a fine, powdery sediment.

Indole not produced.

Milk: Growth with no coagulation.

Glucose and sucrose not fermented.

Coagulated albumin: Not attacked.

Meat medium: Abundant growth. No record of changes. Capsules are demonstrable in this medium.

Very pathogenic for guinea pigs, which die of septicemia in 24 hours after intraperitoneal inoculation. Less pathogenic for rabbit, which dies after one week.

Toxin not demonstrable in cultures.

Grows at 22°C to 37°C.

Obligately anaerobic.

Source: From feces of a diarrheal infant.

Habitat: Not determined, other than this single isolation.

20. **Clostridium bifermentans** (Weinberg and Seguin) Bergey et al. (*Bacillus bifermentans sporogenes* Tissier and Martelly, Ann. Inst. Past., *16*, 1902, 894; *Bacillus bifermantans* Weinberg and Seguin, La Gangrène Gazeuse, Paris, 1918, 128; *Martellillus bifermentans* Heller, Jour. Bact., *7*, 1922, 8; Bergey et al., Manual, 1st ed., 1923, 323.) From Latin, *bis*, twice, and *fermentum*, a ferment.

Closely related if not identical species: *Bacillus centrosporogenes* Hall, Jour. Inf. Dis., *30*, 1922, 464 (*Clostridium centrosporogenes* Bergey et al., Manual, 1st ed., 1923, 322); *Bacillus oedematis sporogenes* Sordelli, Compt. rend. Soc. Biol., Paris, *89*, 1923, 55 (Anaérobie agent de gangrène gazeuse, Sordelli, *ibid.*, *87*, 1922, 838; *Bacillus sordelli* Hall and Scott, Jour. Inf. Dis., *41*, 1927, 329; *Bacillus sporogenes oedematis* Piening, Thesis, Hanover, 1931, (?), cited from McCoy and McClung, The Anaer. Bact., etc., *2*, 1939, 492; *Clostridium sordelli* Prévot, Ann. Inst. Past., *61*, 1938, 83); *Clostridium oedematoides* Meleney, Humphreys and Carp, Proc. Soc. Expt. Biol. and Med., *24*, 1926–27, 677.

Varying degrees of virulence and toxicity occur in the above group. The more toxic and virulent strains are commonly referred to as *Bacillus sordelli*, although otherwise an apparently homogeneously organized group.

Probable synonyms: *Clostridium foetidum* Liborius, Ztschr. f. Hyg., *1*, 1886, 160 (*Cornilia foetida* Trevisan, I generi e le specie delle Batteriacee, 1889, 22; *Bacillus foetidus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *10*, 1898, 128; not *Bacillus foetidus* Trevisan, *loc. cit.*, 16); *Bacillus liquefaciens magnus* Lüderitz, Ztschr. f. Hyg., *5*, 1889, 146 (*Cornilia magna* Trevisan, *loc. cit.*, 22; *Bacillus magnus* Herfeldt, Cent. f. Bakt., II Abt., *1*, 1895, 78; *Bacillus magnus liquefaciens* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., Paris, 1914, 327; *Bacillus foetidus clostridiiformis* LeBlaye and Guggenheim, *idem*, 327); *Clostridium foetidum carnis* Salus, Arch. f. Hyg., *51*, 1904, 121 (*Clostridium carnis foetidum* and *Clostridium foetidum* Salus, *ibid.*, 121 and 124; *Clostridium carnofoetidus* McCrudden, Jour. Biol. Chem., *8*, 1910–11, 109; *Clostridium carnofoetidum* Prévot, Ann. Inst. Past., *61*, 1938, 84); *Bacillus sporogenes* var. *B*, Metchnikoff, Ann. Inst. Past., *22*, 1908, 944 (*Clostridium sporogenes* var. *B*, Prévot, Ann. Inst. Past., *61*, 1938, 83); *Bacillus sporogenes foetidus* Choukévitch, Ann. Inst. Past., *25*, 1911, 257 (*Bacillus foetidus* Choukévitch, *ibid.*, 258); *Bacillus putrificus tenuis* Zeissler, Ztschr. f. Infkrnkh. u. Hyg. Haust., *21*, 1920–21, 13; *Bacillus nonfermentans* Hall and Whitehead, Jour. Inf. Dis., *41*, 1927, 65.

Rods: 0.8 to 1.0 by 5.0 to 6.0 microns, occurring singly, in pairs, and in short chains. Spores oval, central to excentric, not distinctly swelling rods. Motile in very young cultures only (less than 24 hours old). Gram-positive.

Gelatin: Liquefied and blackened.

Agar surface colonies (anaerobic): Circular, crenated to amoeboid.

Blood agar surface colonies (anaerobic): Small, transparent, hemolytic, becoming opaque, yellowish, spreading.

Broth: Turbidity and gas. Thick mucoid sediment.

Litmus milk: Slowly coagulated. Slowly peptonized, with little gas.

Indole is formed.

Nitrites not produced from nitrates.

Hydrogen sulfide is produced.

Acid and gas from glucose, fructose, mannose and maltose. Lactose, sucrose and inulin not fermented. Records suggest variability in glycerol and salicin.

Coagulated albumin rapidly liquefied and blackened.

Blood serum liquefied and blackened.

Brain medium digested and blackened.

Egg-meat medium digested and blackened. Tyrosin crystals in 8 to 10 days.

Pathogenicity: Variable with the strain; some kill rabbits in 24 hours; others produce only slight edema, while some show no effect.

Toxicity: Likewise variable, from acute to none.

Optimum temperature from 30°C to 37°C. Can grow at 50°C.

Anaerobic.

Source: Originally from putrid meat; subsequently from gaseous gangrene.

Habitat: Occurs commonly in feces, soil and sewage. Widely distributed in nature.

21. **Clostridium mucosum** (Klein) Bergey et al. (*Bacillus mucosus* Klein, Cent. f. Bakt., I Abt., *29*, 1901, 991; not *Bacillus mucosus* Zimmermann, Die Bakt. unserer Trink- u. Nutzwässer, Chemnitz, *2*, 1894, 8; *Bacterium mucosum* Migula, Syst. d. Bakt., *2*, 1900, 315; *Bacillus kleinii* Buchanan and Hammer, Iowa Agric. Exp. Sta. Res. Bull. 22, 1915, 276; not *Bacillus kleinii* Migula, Syst. d. Bakt., *2*, 1900, 766; not *Bacillus kleinii* Trevisan, *in litt.* cited from De Toni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 946; *Clostridium kleinii* Bergey et al., Manual, 1st ed., 1923, 321; Bergey et al., Manual, 4th ed., 1934, 472; not *Clostridium mucosum* Simola, cited from Prévot, Man. d. Class., etc., 1940, 112; *Endosporus mucosus* Prévot, Ann. Inst. Past., *61*, 1938, 75.) From Latin, slimy.

Rods: 1.3 by 2.0 to 5.0 microns, occurring singly, in pairs and in chains. Motile. Spores oval, central, not swelling rods. Gram-negative (Klein, *loc. cit.*). Young cultures Gram-positive (Buchanan and Hammer, *loc. cit.*).

No growth in media without carbohydrates.

Glucose gelatin: Slowly liquefied.

Glucose gelatin surface colonies (anaerobic): Small, gray.

Glucose gelatin stab: Villous growth. Slow liquefaction.

Glucose agar slant (anaerobic): Thin, veil-like layer. Slimy condensation water.

Glucose broth: Turbid. Gas bubbles.

Litmus milk: Acid; slowly coagulated, slimy. Gas formed. Odor of butyric acid.

Potato: No growth.

Indole not formed.

Nitrites not produced from nitrates.

Acid and gas from glucose.

Blood serum: No growth.

Non-pathogenic.

Grows at 37°C.

Anaerobic.

Source: Blood sausage (Blutwurst).

Habitat: Not determined, other than this source.

22. **Clostridium pruchii** (Buchanan and Hammer) Bergey et al. (*Bacillus lactis pruchii* Conn, Esten and Stocking, 18th Ann. Rept. Storrs Agric. Exp. Sta., 1906, 179; *Bacillus pruchii* Buchanan and Hammer, Iowa Agric. Exp. Sta. Res. Bull. No. 22, 1915, 276; Bergey et al., Manual, 1st ed., 1923, 322.) Named for M. J. Prucha, American bacteriologist.

Rods: Variable in size, with club-shaped ends. Motile, with peritrichous

flagella. Spores central, oval, not swelling rods. Gram-positive.

Gelatin: Rapid, stratiform liquefaction. Reddish-yellow sediment.

Agar surface colonies (anaerobic): Round, flat, white, smooth, opaque.

Agar slant (anaerobic): Luxuriant, white, viscid.

Broth: Turbid, with flocculent pellicle and gray viscous sediment.

Litmus milk: Acid; slowly coagulated, becoming slimy yellow.

Potato: Thin, brownish, spreading.

Indole not formed.

Nitrites not produced from nitrates.

Acid but no gas from glucose.

Coagulated albumin not recorded.

Blood serum not liquefied.

Non-pathogenic.

Optimum temperature 30°C. Grows well between 20°C and 37°C.

Anaerobic.

Source: From slimy milk.

Habitat: Not determined, other than this source.

23. **Clostridium cylindrosporum** Barker and Beck. (Jour. Biol. Chem., *141*, 1941, 3.) Named from the characteristic spore morphology.

Rods: 1.0 by 4.0 to 7.0 microns, straight. Motile with peritrichous flagella. Spores elongate to cylindrical, 1.0 to 1.1 by 1.7 to 3.0 microns, central, subterminal to terminal, with little or no swelling of rods. Gram-negative.

Iron-gelatin (Spray): No growth.

Deep plain agar: No growth.

Deep uric acid agar colonies: Whitish, compact, lobate, 1 to 2 mm in diameter, with irregular edges, surrounded by a zone of precipitated ammonium ureate which gradually disappears.

Plain broth: No growth.

Glucose broth: No growth.

Iron-milk (Spray): No growth.

Indole not recorded (probably negative).

Nitrites not recorded (probably negative).

Glucose not fermented.

Carbohydrates not fermented.

Cellulose not fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not digested or blackened.

Pathogenicity not recorded (probably non-pathogenic).

Optimum temperature about 35°C.

Optimum reaction about pH 7.5; lower limit for growth pH 6.5.

Anaerobic.

Distinctive characters: Requires uric acid, or certain other purines, as a primary source of carbon and energy. The purines are converted into ammonia, CO_2, acetic acid and a little glycine. This organism is physiologically similar to *Clostridium acidi-urici*, but may be readily distinguished from the latter by its morphology.

Source: A single strain isolated from soil.

Habitat: Probably soil, although only this single isolation is recorded.

24. **Clostridium perfringens** (Veillon and Zuber) Holland.* *Clostridium perfringens* Type A, Wilsdon. (*Bacillus aerogenes capsulatus* Welch and Nuttall, Johns Hopkins Hosp. Bull. *3*, 1892, 81 (*Bacillus capsulatus aerogenes* Lehmann and Neumann, Bakt. Diag., 2 Aufl., *2*, 1899, 327); *Bacillus phlegmones emphysematosae* Fraenkel, Ueber Gasphleg-

* Because of use of the species name *perfringens* by the Permanent Standards Commission of the Health Organization of the League of Nations (Report of the Permanent Commission on Biological Standardization, London, June 23, 1931), the use of this name has been continued although it is preceded by a valid binomial (*Bacillus emphysematosus* Kruse).

monen, Leipzig, 1893, 47; *Bacillus emphysematosus* Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 242; *Bacterium aerogenes capsulatus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 125; *Bacterium emphysematosus* Chester, *ibid.*, 126; *Bacillus emphysematis vaginae* Lindenthal, Wien. klin. Wchnschr., *10*, 1897, 42; *Bacillus perfringens* Veillon and Zuber, Arch. Méd. Expt. et Anat. Path., *10*, 1898, 539; *Bacillus capsulatus anaerobius* and *Bacillus capsulatus aerogenes* Binaghi, Cent. f. Bakt., II Abt., *4*, 1898, 920; *Granulobacillus saccharobutyricus immobilis liquefaciens* Schattenfroh and Grassberger, Cent. f. Bakt., II Abt., *5*, 1899, 702 (*Granulobacillus immobilis* Schattenfroh and Grassberger, Arch. f. Hyg., *37*, 1900, 68; *Bacillus amylobacter immobilis* Gratz and Vas, Cent. f. Past., *60*, 1938, 295).

Bacillus zoodysenteriae Weinberg et al., Les Mic. Anaér., 1937, 256 (*Bacillus zoodysenteriae hungaricus* Detre, Cent. f. Bakt., I Abt., Orig., *104*, 1927, 251; *Welchia perfringens* var. *zoodysenteriae* Prévot, Ann. Inst. Past., *61*, 1938, 78).

Clostridium perfringens var. *anaerogenes* Hauduroy et al., Dict. d. Bact. Path., 1937, 122 (Unnamed species of Grootten, Compt. rend. Soc. Biol., Paris, *100*, 1929, 499).

Rods: Short, thick, 1.0 to 1.5 by 4.0 to 8.0 microns, occurring singly and in pairs, less frequently in short chains. Non-motile. Spores oval, central to excentric, not swelling rods. Encapsulated. Gram-positive.

Gelatin: Liquefied and blackened.

Agar surface colonies (anaerobic): Circular, moist, slightly raised, opaque center, entire.

Broth: Turbid; peptolytic. Clearing with viscid sediment.

Litmus milk: Acid, coagulated. Clot torn with profuse gas formation, but not digested.

Potato: Thin, grayish-white streak; gas in subtended liquid.

Indole not formed.

Nitrites produced from nitrates.

Acid and gas from glucose, fructose, galactose, mannose, maltose, lactose, sucrose, xylose, trehalose, raffinose, starch, glycogen and inositol. Mannitol not fermented. Salicin rarely fermented. Action on inulin and glycerol variable.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Egg-meat: Profuse gas production in 8 hours. The meat is reddened and the liquid becomes turbid. No digestion.

Pathogenic for guinea pig, pigeon and mouse. Produces an exotoxin for which an antitoxin can be prepared.

Optimum temperature 35°C to 37°C. Can grow at 50°C.

Anaerobic.

Distinctive characters: Stormy fermentation of milk, combined with non-motility.

Source: Gaseous gangrene, feces, milk and soil.

Habitat: Widely distributed in feces, sewage and soil.

25. **Clostridium sphenoides** (Bulloch et al.) Bergey et al. (*Bacillus sphenoides* Bulloch, Bulloch, Douglas, Henry, McIntosh, O'Brien, Robertson and Wolf, Med. Res. Counc., Spec. Rept. Ser. No. 39, 1919, 43; *Douglasillus sphenoides* Heller, Jour. Bact., *7*, 1922, 5; Bergey et al., Manual, 1st ed., 1923, 331; *Plectridium sphenoides* Prévot, Ann. Inst. Past., *61*, 1938, 88.) From Greek, wedge-shaped.

Described from Bulloch et al., *loc. cit.*, as amplified by Hall, Jour. Inf. Dis., *30*, 1922, 502.

Rods: Small, fusiform in vegetative state, occurring singly, in pairs and occasionally in short chains. Sporulating cells cuneate. Motile. Spores spherical, subterminal, becoming terminal on

maturation, swelling rods. Gram-positive only in young cultures.

Gelatin: Not liquefied.

Agar surface colonies (anaerobic): Circular, or slightly irregular, entire.

Blood agar surface colonies (anaerobic): Minute dew-drops, becoming whitish, opaque. Blood is hemolyzed.

Deep agar colonies: Minute, opaque, smooth disks.

Broth: Turbid.

Litmus milk: Acid; slowly and softly coagulated. Clot not digested.

Indole not formed (indole formed by Tholby strain, Stanley and Spray, Jour. Bact., *41*, 1941, 256).

Nitrites produced from nitrates.

Acid and gas from glucose, galactose, maltose, lactose and salicin. Inulin, glycerol and dulcitol not fermented. Strains are apparently variable on mannitol, sucrose, dextrin and starch.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Non-pathogenic for guinea pig and rabbit.

Optimum temperature not determined. Grows well at 30°C to 37°C.

Anaerobic.

Source: From gangrenous war wounds.

Habitat: Not determined, other than this source.

26. **Clostridium innominatum** Prévot. (Bacillus E, Adamson, Jour. Path. and Bact., *22*, 1918–19, 391; Prévot, Ann. Inst. Past., *61*, 1938, 85.) From Latin, remaining unnamed.

Rods: Very small, thick, tapering at one or both ends, occurring singly, paired, in chains and filaments. Involution forms abundant on glucose agar. Motile. Spores small, spherical, subterminal, swelling rods. Gram-positive, quickly becoming Gram-negative.

Gelatin: Not liquefied.

Glucose agar surface colonies (anaerobic): Two forms are produced: 1) Circular, entire edge, opaque; 2) Diffuse, spreading, irregular and translucent.

Plain agar surface colonies (anaerobic): Small, circular, entire edge, whitish-translucent, becoming opaque-yellowish with age.

Plain broth: Moderate turbidity, clearing by sedimentation in 3 to 4 days.

Glucose broth: More abundant turbidity and slight gas production.

Milk: Slowly acidified but not clotted. No further change.

Glucose, maltose, lactose and mannitol fermented with acid and gas.

Sucrose not fermented.

Coagulated albumin: Not digested or blackened.

Meat medium: Not digested or blackened.

Blood serum: Not digested or blackened.

Brain medium: Not digested or blackened.

Non-pathogenic (Prévot, *loc. cit.*).

Grows well at 37°C.

Anaerobic.

Source: From septic and gangrenous war wounds.

Habitat: Not determined, other than this source.

27. **Clostridium filiforme** Bergey et al. (*Bacillus regularis filiformis* Debono, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 234; Bergey et al., Manual, 1st ed., 1923, 331.) From Latin, thread-like.

Rods: 0.5 to 0.8 by 3.0 to 5.0 microns, slender, occurring singly, in pairs, in chains and filaments. Non-motile. Spores very small, spherical, subterminal, or occasionally terminal, not swelling rods. Gram-positive.

Gelatin: Not liquefied.

Deep gelatin colonies: Small, gray, filamentous.

Deep agar colonies: Irregular, gray, translucent, filamentous.

Broth: Uniform turbidity.

Litmus milk: Acid, but no further change.

Potato: Gray, filamentous; substance not digested.

Acid and gas from glucose and lactose. Acid only from sucrose and dulcitol. Starch not fermented.

Coagulated albumin not liquefied.

Grows in gelatin at 22°C.

Anaerobic.

Source: From human feces.

Habitat: Not determined, other than this source.

28. **Clostridium sartagoformum** Partansky and Henry. (Jour. Bact., *30*, 1935, 570.) From Latin, shaped like a frying-pan.

Rods: 0.3 to 0.5 by 3.5 to 6.0 microns. Slender, curved, with rounded ends, occurring singly. Motile. Spores oval, terminal, swelling rods. Gram-positive.

Gelatin: Not liquefied.

Agar surface colonies (anaerobic): Convex, discrete, circular, transparent to white and opaque. Surface moist and smooth.

Blood agar not hemolyzed.

Deep agar colonies: Regular, lenticular, smooth.

Broth: Clear; no growth.

Glucose broth: Turbid, with gas bubbles.

Litmus milk: Acid; slowly coagulated, with some gas formation. Clot not digested.

Potato: Very scant growth. No gas in surrounding liquid.

Indole not formed.

Nitrites not produced from nitrates.

Acid and gas from xylose, glucose, fructose, galactose, sucrose, lactose, maltose, raffinose, inulin, salicin, mannitol, acetate and butyrate. Starch, ethanol, glycerol and dulcitol not fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied. Scant growth.

Brain medium not blackened or digested. Some gas is formed.

Optimum temperature 37°C.

Anaerobic.

Distinctive character: Ferments sulfite waste liquor in 40 per cent concentration, forming butyric and acetic acids, H_2 and CO_2.

Source: From garden soil and from stream and lake mud.

Habitat: Not recorded; obviously soil. Distribution undetermined.

29. **Clostridium paraputrificum** (Bienstock) Snyder. (Art V, Bienstock, Fortschr. d. Med., *1*, 1883, 612; *Bacillus diapthirus* Trevisan, I generi e le specie delle Batteriacee, 1889, 15; *Bacillus paraputrificus* Bienstock, Ann. Inst. Past., *20*, 1906, 413, and Strassburger Med. Zeit., *3*, 1906, 111; *Bacillus paraputrificus coli* Henry, Brit. Med. Jour., *1*, 1917, 763; *Tissierillus paraputrificus* Heller, Jour. Bact., *7*, 1922, 27; Snyder, Jour. Bact., *32*, 1936, 401; *Plectridium paraputrificum* Prévot, Man. d. Class., etc., 1940, 160.) From Latin, also putrefying.

Probable synonyms: Köpfchenbakterien, Escherich, Fortschr. d. Med., *8*, 1885, 515; Bacillus No. 3, Rodella, Ztschr. f. Hyg., *39*, 1902, 209 (*Plectridium fluxum* Prévot, Ann. Inst. Past., *61*, 1938, 87); Art XI, Hibler, Cent. f. Bakt., I Abt., *25*, 1899, 516 (Art IX, Hibler, Untersuch. ü. d. Path. Anaer., 1908, 3 and 407; *Plectridium nonum* Prévot, Ann. Inst. Past., *61*, 1938, 88); Anaerobe b, Dalyell, Jour. Path. and Bact., *19*, 1914–15, 281; *Bacillus innutritus* Kleinschmidt, Monatschr. f. Kinderheilkunde, *62*, 1934, 18 (*Palmula innutrita* Prévot, Ann. Inst. Past., *61*, 1938, 89; *Acuformis innutritus* Prévot, Man. d. Class., etc., 1940, 165).

Described from Hall and Snyder, Jour. Bact., *28*, 1934, 181.

Rods: 0.3 to 0.5 by 2.0 to 6.0 microns. Straight or slightly curved, single, in pairs, or in short chains. Ends rounded. Motile with peritrichous flagella. Spores oval, terminal, swelling rods. Gram-positive.

Gelatin: Not liquefied. Gas is formed.

Blood agar surface colonies (anaerobic): Delicate, irregular, round-topped dewdrops. Non-hemolytic.

Deep agar colonies: Small, irregular, opaque, dense, cottony masses. Gas is formed.

Broth: Diffuse turbidity.

Milk: Usually coagulated in from 6 to 10 days. Abundant gas, but no peptonization.

Indole is not formed.

Acid and gas from glucose, fructose, galactose, maltose, lactose, sucrose, raffinose, dextrin, soluble starch, amygdalin and salicin. Xylose, inulin, mannitol and glycerol not fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied or discolored.

Brain medium not blackened or digested. Non-proteolytic.

Non-pathogenic for guinea pig and rabbit.

Grows well at 37°C.

Anaerobic.

Source: Feces, gaseous gangrene, and postmortem fluid and tissue cultures.

Habitat: Undetermined, other than these sources. Evidently occurs commonly in intestinal canal of human beings.

30. **Clostridium cochlearium** (Bulloch et al.) Bergey et al. (Bacillus Type IIIc, McIntosh, Med. Res. Counc., Spec. Rept. Ser. No. 12, 1917, 20; *Bacillus cochlearius* Bulloch, Bulloch, Douglas, Henry, McIntosh, O'Brien, Robertson and Wolf, Med. Res. Counc., Spec. Rept. Ser. No. 39, 1919, 40; *Flemingillus cochlearius* Heller, Jour. Bact., 7, 1922, 5; Bergey et al., Manual, 1st ed., 1923, 333; *Plectridium cochlearium* Prévot, Ann. Inst. Past., *61*, 1938, 88; *Plectridium incertum* Prévot, *idem.*) From Latin, spoon-shaped.

Rods: Slender, straight, occurring chiefly singly, or infrequently in pairs and in short chains. Motile with peritrichous flagella. Spores oval, terminal, swelling rods. Weakly Gram-positive.

Gelatin: Not liquefied.

Agar surface colonies (anaerobic): Circular, clear, entire, or with crenated edge.

Deep agar colonies: Lenticular, entire.

Broth: Turbid.

Litmus milk: Unchanged.

Glucose not fermented.

Carbohydrates not fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Meat medium: Slightly reddened. Not blackened or digested. Little gas of non-putrefactive odor.

Non-pathogenic.

Optimum temperature 30°C to 35°C.

Anaerobic.

Source: From human war wounds and septic infections.

Habitat: Not determined, other than these sources. Probably occurs in soil.

31. **Clostridium kluyveri** Barker and Taha. (Jour. Bact., *43*, 1942, 347.) Named for A. J. Kluyver, in whose laboratory the organism was discovered.

Rods: 0.9 to 1.1 by 3.0 to 11.0 microns. Straight to slightly curved; usually single, but also paired and occasionally in long chains. Motile with peritrichous flagella. Spores oval, terminal, swelling rods. Generally Gram-negative; some strains weakly Gram-positive when young.

Iron-gelatin (Spray): No growth.

Surface agar colonies (anaerobic): Growth slow and restricted by residual traces of oxygen. Rough and smooth colonies are produced.

Deep agar colonies (yeast autolysate and C_2H_5OH): Small colonies (1 to 3 mm) after 2 to 3 days; two types are formed: a) fluffy spheres with dense nuclear center and filamentous periphery; b) compact, lenticular colonies. Little gas is formed.

Plain broth: No growth.

Glucose broth: No growth.

Milk or iron-milk (Spray): No growth.

Indole not recorded (probably negative).

Nitrites not recorded (probably negative).

Glucose not fermented.

Carbohydrates not fermented.

Cellulose not fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not digested or blackened.

Probably non-pathogenic.

Optimum temperature about 34°C. Grows between 19°C and 37°C.

Optimum reaction about pH 6.8. Range for growth pH 6.0 to 7.5.

Anaerobic.

Distinctive characters: Large size of cells, and slow growth, accompanied by non-putrefactive odor of caproic acid and of higher alcohols. Growth is exceptionally favored by synergistic association with *Methanobacterium omelianskii*. In pure culture a high concentration of yeast autolysate is required. Caproic acid is formed from ethyl alcohol.

Source: From black mud of fresh water and marine origin.

Habitat: Not determined, other than these sources. Evidently widely dispersed in nature.

32. **Clostridium acidiurici** (Liebert) Barker. (*Bacillus acidi urici* Liebert, Koninkl. Akad. v. Wetensch., Proc. Sect. Sci., Amsterdam, *12*, 1909, 55; Barker, Jour. Bact., *36*, 1938, 323.) Named from its characteristic ability to ferment uric acid.

Rods: 0.5 to 0.7 by 2.5 to 4.0 microns; straight. Motile with peritrichous flagella. Spores oval, terminal, swelling rods. Most strains Gram-negative. A few strains weakly Gram-positive, quickly becoming Gram-negative.

Iron-gelatin (Spray): No growth.

Deep plain agar: No growth.

Deep uric acid agar colonies: Whitish, compact, lobate, 1 to 2 mm in diameter, with irregular edge; surrounded by a temporary zone of precipitated ammonium ureate which gradually disappears.

Surface uric acid agar colonies (anaerobic): Variable with strain and with moisture of medium. Colonies 1 to 2 mm in diameter, opaque, white, raised, round, smooth edge, with concentric surface markings, and of rubbery consistency. Other colonies may be very thin, soft, transparent, with fimbriate projections, spreading to cover almost the entire plate. Intermediate colony types also observed.

Plain broth: No growth.

Glucose broth: No growth.

Iron-milk (Spray): No growth.

Indole not recorded (probably negative).

Nitrites not recorded (probably negative).

Glucose not fermented.

Carbohydrates not fermented.

Cellulose not fermented.

Coagulated albumin not liquefied

Blood serum not liquefied.

Brain medium not digested or blackened.

Probably non-pathogenic.

Optimum temperature about 35°C.

Optimum reaction about pH 7.5; lower limit for growth about pH 6.5.

Anaerobic.

Distinctive characters: Requires uric acid, or certain other purines, as a primary source of carbon and energy. The purines are converted mainly into ammonia, CO_2 and acetic acid. During growth the medium tends to become alkaline (pH 8.0 to 8.5); there is no visible evolution of gas.

Source: From soils of diverse origin.

Habitat: Evidently widely dispersed in soils. Present in fecal material of yellow-shafted flicker (*Colaptes auratus*).

33. **Clostridium capitovale** (Snyder and Hall) Snyder. (*Bacillus capitovalis* Snyder and Hall, Cent. f. Bakt., I Abt., Orig., *135*, 1935, 290; *Clostridium capitovalis* Snyder, Jour. Bact., *32*, 1936, 401; *Plectridium capitovalis* Prévot, Ann. Inst. Past., *61*, 1938, 87.) From Latin, oval-headed.

Rods: 0.5 to 0.8 by 2.0 to 2.5 microns. Slender, commonly curved, with rounded ends, occurring singly, in pairs, and rarely in short chains. Motile with long peri-

trichous flagella. Spores oval, terminal, swelling rods. Gram-positive.

Gelatin: Liquefied.

Blood agar surface colonies (anaerobic): Tiny, transparent, round or irregular dew-drops, becoming opaque. Non-hemolytic.

Deep agar colonies: Small, opaque, lenticular to heart-shaped.

Tryptone broth: Turbid. Gas is formed.

Milk: Often, but not invariably, clotted. Acid is formed. Clot, when formed, is not digested.

Indole not formed.

Nitrites not produced from nitrates.

Acid and gas from glucose, fructose and galactose. Maltose, lactose, sucrose, raffinose, xylose, inulin, dextrin, starch, cellulose, amygdalin, salicin, mannitol and glycerol not fermented.

Coagulated albumin liquefied.

Blood serum slowly softened and partially liquefied. Not blackened. Mildly proteolytic.

Brain medium is blackened; slightly softened, but not conspicuously liquefied.

Pathogenicity: Guinea pig may show slight subcutaneous edema; usually no effect. Non-pathogenic for rabbit.

Grows at 37°C.

Anaerobic.

Source: Human feces, gaseous gangrene and septicemia.

Habitat: Not determined, other than these sources.

34. **Clostridium parabifermentans** *comb. nov.* (*Bacillus parabifermentans sporogenes* de Gasperi, Compt. rend. Soc. Biol., Paris, *67*, 1909, 492.) From Greek, *para*, near, and Latin, *bis*, twice, and *fermentum*, a ferment.

Rods: 0.5 to 0.7 by 4.0 to 5.0 microns, occurring singly, in pairs and in chains of 3 to 5 cells. Motile. Spores oval, terminal, swelling rods. Gram-positive.

Glucose gelatin: Rapid growth with liquefaction.

Deep glucose agar colonies: Lenticular, regular, opaque, whitish. Agar disrupted by considerable gas of putrefactive odor.

Glucose broth: Abundant growth with uniform turbidity and with viscous sediment.

Milk: Acidified but not coagulated. Casein slowly precipitated with slow, but complete, digestion.

Indole formed in trace.

Glucose, lactose and sucrose fermented to acids. (Gas not recorded.) Starch is not fermented.

Coagulated albumin actively liquefied.

Non-pathogenic for mouse.

Grows between 22°C and 37°C.

Anaerobic.

Source: From putrefying game (pheasant and guinea-fowl).

Habitat: Undetermined, other than this source.

35. **Clostridium ovalare** Bergey et al. (*Bacillus putrificus ovalaris* Debono, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 231; Bergey et al., Manual, 1st ed., 1923, 336; *Plectridium ovalaris* Prévot, Ann. Inst. Past., *61*, 1938, 88.) From Latin, oval.

Rods: 0.3 to 0.4 by 6.0 to 8.0 microns, straight or curving, ends rounded, occurring singly, in pairs and in short chains. Motile. Spores oval, terminal, swelling rods. Gram-positive.

Gelatin: Rapidly liquefied.

Deep glucose agar colonies: Small, globular, entire, becoming brownish. Scant gas is formed.

Broth: Turbid.

Litmus milk: Acid, peptonized without coagulation.

Indole not formed.

Acid and scant gas from glucose and lactose. Acid only from sucrose. Dulcitol not fermented.

Coagulated albumin rendered transparent, then slowly peptonized, with a putrefactive odor.

Grows at 22°C and at 37°C.

Anaerobic.

Source: Originally from putrid meat, later from feces.

Habitat: Not determined, other than these sources.

36. **Clostridium zoogleicum** Bergey et al. (*Bacillus sporogenes zoogleicus* Distaso, Cent. f. Bakt., I Abt., Orig., *59*, 1911, 99; Bergey et al., Manual, 1st ed., 1923, 335.) From Greek, zoogleal.

Rods: Fairly long, occurring singly, in pairs and in short chains. Motile. Spores large, oval, terminal, swelling rods. Gram-positive.

Gelatin: Growth and liquefaction not recorded.

Deep agar colonies: Small, gray, slightly opaque, becoming heart-shaped. Gas is not formed.

Broth: Turbid, then clearing with zoogleal sediment.

Litmus milk: Slowly coagulated, then digested. Litmus reduced.

Indole is formed in trace.

Acid but no gas from glucose. Lactose and sucrose not fermented.

Coagulated albumin liquefied, leaving a clear fluid and zoogleal sediment.

Grows at 37°C.

Anaerobic.

Source: From human feces.

Habitat: Undetermined, other than this source.

37. **Clostridium thermosaccharolyticum** McClung. (Jour. Bact., *29*, 1935, 200; *Terminosporus thermosaccharolyticus* Prévot, Ann. Inst. Past, *61*, 1938, 86.) From Greek, heat, and sugar-digesting.

Rods: 0.4 to 0.7 by 3.5 to 7.5 microns, slender, granulated, occurring singly and in pairs, not in chains. Motile with peritrichous flagella. Spores spherical, terminal, swelling rods. Gram-negative.

Gelatin: Not liquefied.

Pea-infusion agar surface colonies (anaerobic): Granular, grayish-white, raised center, with feathery edges.

Deep glucose-tryptone agar colonies: Small, lenticular, smooth.

Liver-infusion broth over liver meat: Turbidity and gas.

Litmus milk: Litmus reduced. Acid and slow but firm coagulation; coagulum split with gas. Clot not digested.

Indole not formed.

Nitrites not produced from nitrates.

Cellulose not fermented.

Acid and gas from arabinose, fructose, galactose, glucose, mannose, xylose, cellobiose, lactose, maltose, sucrose, trehalose, dextrin, glycogen, corn-starch, amygdalin, esculin, α-methyl glucoside and salicin. Raffinose weakly fermented. Rhamnose, inulin, pectin, erythritol, inositol, mannitol, glycerol, quercitol and Ca-lactate not fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Meat-medium not blackened or digested.

Non-pathogenic on feeding to white rat, or by injection into rabbit.

Optimum temperature 55°C to 62°C. Thermophilic.

Anaerobic.

Source: From hard-swell of canned goods, and from soil.

Habitat: Not determined, other than these sources.

38. **Clostridium caloritolerans** Meyer and Lang. (Jour. Inf. Dis., *39*, 1926, 321; *Plectridium caloritolerans* Prévot, Ann. Inst. Past., *61*, 1938, 87.) From Latin, heat-enduring.

Rods: 0.5 to 0.8 by 8.0 to 10.0 microns, with rounded ends, occurring singly, in pairs, in chains and in curved filaments. Motile with peritrichous flagella. Spores spherical or pear-shaped, terminal, swelling rods. Gram-positive.

Gelatin: Not liquefied.

Glucose blood agar surface colonies (anaerobic): Small, flat, grayish, rhizoidal. Non-hemolytic.

Deep liver agar colonies: Small, flat, transparent disks with large polar tufts. Some colonies become fluffy.

Broth: Slight turbidity.

Glucose broth: Abundant turbidity,

with clearing by sedimentation. Gas is formed.

Brom cresol purple milk: No change.

Indole not formed.

Acid and gas from glucose, galactose and maltose. Fructose feebly fermented. Lactose, sucrose, raffinose, inulin, salicin, mannitol, inositol and glycerol not fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Beef-heart mash medium: Reddened; not blackened or digested.

Non-pathogenic for mouse, guinea pig and rabbit.

Optimum temperature not determined. Grows at 37°C.

Anaerobic.

Source: From an old culture of *Clostridium parabotulinum* Type A.

Habitat: Not determined, other than this single isolation.

39. **Clostridium tetanoides** (Adamson) Hauduroy et al. (Unnamed anaerobe, Adamson and Cutler, Lancet, *1*, 1917, 688; *Bacillus tetanoides* (*A*) Adamson, Jour. Path. and Bact., *22*, 1918–19, 382; Hauduroy et al., Dict. d. Bact. Path., 1937, 140; *Palmula macrospora* Prévot, Ann. Inst. Past., *61*, 1938, 88; *Acuformis macrosporus* Prévot, Man. d. Class., etc., 1940, 166.) From Latin, tetanus-like.

Rods: 1.0 to 2.0 by 4.0 to 12.0 microns (averaging 1.0 to 1.5 by 6.0 to 7.0 microns), with rounded to slightly tapered ends, occurring singly, in pairs and in chains of 3 to 5 cells, but not in filaments. Motile only in young cultures. Spores large, spherical, terminal, swelling rods. Gram-positive in young cultures, soon becoming Gram-negative.

Gelatin: Not liquefied.

Glucose agar surface colonies (anaerobic): Circular, regular, opaque, bluish-gray, moist, shining, thick, raised. Surface flat, becoming conical in center with age. On moist medium showing radiating, dendritic branching. Growth becomes tenacious-mucoid.

Plain agar surface colonies (anaerobic): Confluent, becoming an opaque film. Isolated colonies circular to slightly irregular. Dendritic branching and mucoid tendency less evident than on glucose agar.

Glucose agar stab: Thick growth along stab, starting 0.5 cm below surface. No gas or splitting of medium.

Neutral-red glucose agar: Reduced to orange by transmitted, and greenish-fluorescent by reflected light.

Plain broth: Early slight turbidity, with clearing and mucoid sedimentation.

Glucose broth: Abundant turbidity and profuse mucoid sediment.

Milk: Slight and slowly increasing alkalinity, with slow separation of casein. No further change.

Indole: Trace formed in broth.

Glucose and maltose fermented with acid but no gas. Lactose, sucrose, mannitol, starch and cellulose not fermented.

Coagulated albumin: Not digested or blackened.

Meat medium: Not digested or blackened.

Blood serum: Not digested or blackened.

Brain medium: Not digested or blackened.

Non-pathogenic for guinea pig and rabbit.

Optimum temperature not recorded. Grows well at 37°C.

Anaerobic.

Source: From war wounds, from post-mortem blood culture, and from garden soil.

Habitat: Not determined, other than these sources.

40. **Clostridium tetani** (Flügge) Holland. (Tetanusbacillen and Tetanuserreger, Nicolaier, Deuts. Med. Wchnschr., *10*, 1884, 843; *Bacillus tetani* Flügge, Die Mikroorg., 2 Aufl., 1886, 274; *Pacinia nicolaieri* Trevisan, I generi e le specie delle Batteriacee, 1889, 23; *Plectridium*

tetani Fischer, Jahrb. f. Wissensch. Botanik, *27*, 1895, (147?); Holland, Jour. Bact., *5*, 1920, 220; *Nicollaierillus tetani* Heller, Jour. Bact., *7*, 1922, 7.) From *tetanus*, lockjaw.

Rods: 0.4 to 0.6 by 4.0 to 8.0 microns, rounded ends, occurring singly, in pairs, and often in long chains and filaments. Motile with peritrichous flagella. Spores spherical, terminal, swelling rods. Gram-positive.

Gelatin: Slowly liquefied and blackened.

Serum agar surface colonies (anaerobic): Small, transparent, villous to fimbriate margin.

Blood agar is hemolyzed.

Deep agar colonies: Fluffy, cottony spheres, usually without visible central nucleus.

Broth: Slightly turbid. Gas is formed. Some strains clear quickly by sedimentation.

Litmus milk: Slow precipitation of casein, or soft clotting. Clot slowly softened, but not definitely digested. Little gas is formed.

Indole is formed.

Nitrites not produced from nitrates.

Glucose not fermented.

Carbohydrates not fermented.

Coagulated albumin slowly liquefied.

Blood serum slowly softened, with feeble digestion.

Brain medium blackened and slowly digested. Not actively proteolytic.

Pathogenic and toxic. Forms a potent exotoxin for which an antitoxin is prepared. Toxin intensely toxic on injection but not on feeding.

Optimum temperature 37°C.

Anaerobic.

Source: Originally isolated from animals inoculated with garden soil extract. Frequently isolated from wounds in human tetanus.

Habitat: Common in soils, and in human and horse intestine and feces.

41. Clostridium lentoputrescens Hartsell and Rettger. (Bacillus der Eiweissfäulniss, Bienstock, Fortschr. d. Med., *1*, 1883, 614 (Art IV, Bienstock, *ibid.*, 612; Eiweissbacillus, Bienstock, Ztschr. f. klin. Med., *8*, 1884, 38); *Bacillus albuminis* Schroeter, in Cohn's Kryptogamen-Flora von Schlesien, *3*, 1, 1886, 162; *Bacillus putrificus coli* Flügge, Die Mikroorg., 2 Aufl., 1886, 303; *Pacinia putrifica* Trevisan, I generi e le specie delle Batteriacee, 1889, 23; *Bacillus putrificus* Bienstock, Ann. Inst. Past. *13*, 1899, 861; *Bacillus butyricus putrefaciens* Rodella, Ann. Inst. Past., *19* 1905, 804; *Putribacillus vulgaris* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 343; *Clostridium putrificum* Holland, Jour. Bact., *5*, 1920, 220; *Putrificus bienstocki* Heller, Jour. Bact., *7*, 1922, 8; *Bacillus putrificus* (*coli*) Lehmann and Neumann, Bakt. Diag., 7 Aufl., *2*, 1927, 661; Hartsell and Rettger, Jour. Bact., *27*, 1934, 39 and 497; *Plectridium putrificum* and *Plectridium putrificum* var. *lentoputrescens* Prévot, Ann. Inst. Past., *61*, 1938, 88.) From Latin, slowly made putrid.

Probable synonyms: *Bacillus radiatus* Lüderitz, Ztschr. f. Hyg., *5*, 1889, 149 (*Cornilia radiata* Trevisan, *loc. cit.*, 22; *Bacillus radiatus anaerobius* Hopffe, Ztschr. f. Infkrnkh. u. Hyg. Haust., *14*, 1913, 392); *Bacillus cadaveris sporogenes* (*anaerobicus*) Klein, Cent. f. Bakt., I Abt., *25*, 1899, 279 (*Bacillus cadaveris* Klein, *idem*; not *Bacillus cadaveris* Sternberg, Researches relating to the etiology and prevention of yellow fever, Washington, 1891, 212; not *Bacillus cadaveris* Migula, Syst. d. Bakt., *2*, 1900, 646; *Bacillus cadaveris sporogenes* Klein, *loc. cit.*, 284; *Plectridium cadaveris* Prévot, Ann. Inst. Past., *61*, 1938, 88); Art XIV, von Hibler, Untersuch. ü. d. Path. Anaer., 1908, 3 and 413; *Bacillus tetanoides* (*B*) Adamson, Jour. Bact. and Path., *22*, 1918–19, 388.

Hartsell and Rettger, *loc. cit.*, conclude that their organism differs very materially either from *Clostridium cochlearium* or from *Bacillus putrificus*, as described by Cunningham, Jour. Bact.,

24, 1932, 61, and, as it cannot be definitely related to any other anaerobic species (including the Eiweissbacillus, Bienstock, *loc. cit.*, *Bacillus putrificus coli* Flügge, *loc. cit.*, *Bacillus putrificus* Bienstock, *loc. cit.*, etc.), they propose the name of *Clostridium lentoputrescens* for this species.

Rods: 0.4 to 0.6 by 7.0 to 9.0 microns, with rounded ends, occurring singly, in pairs and in chains. Motile with peritrichous flagella. Spores spherical, terminal, swelling rods. Weakly Gram-positive, becoming Gram-negative.

Gelatin: Liquefied.

Agar surface colonies (anaerobic): Small, circular, flat, edge crenated to filamentous spreading. Develop a ground-glass appearance.

Deep agar colonies: Fluffy spheres with fibrils radiating from a central nucleus.

Blood agar is hemolyzed.

Litmus milk: Slow, soft coagulation or flocculent precipitation. Casein is slowly digested.

Indole is formed (Hall, Jour. Inf. Dis., *30*, 1922, 141). Not formed (Hartsell and Rettger, *loc. cit.*, 509).

Nitrites not produced from nitrates.

Hydrogen sulfide formed in egg-meat medium.

Carbohydrates not fermented. Glucose slightly attacked without distinct acid (Hartsell and Rettger, *loc. cit.*, 508).

Coagulated albumin slowly liquefied and blackened.

Blood serum is liquefied. Gas is formed.

Brain medium slowly blackened and digested.

Egg-meat medium: Slightly turbid liquid. Meat reddened in 7 to 10 days, then digested with a foul odor.

Non-pathogenic for white mouse, guinea pig and rabbit. Filtrate non-toxic on injection or feeding.

Grows well at 37°C.

Anaerobic.

Source: From putrefying meat.

Habitat: Intestinal canal of human. Widely dispersed in soil.

42. **Clostridium filamentosum** Bergey et al. (*Bacillus putrificus filamentosus* Distaso, Cent. f. Bakt., I Abt., Orig., *59*, 1911, 98; Bergey et al., Manual, 1st ed., 1923, 333; *Palmula filamentosa* Prévot, Ann. Inst. Past., *61*, 1938, 88; *Acuformis filamentosus* Prévot, Man. d. Class., etc., 1940, 165.) From Latin, filamentous.

Rods: Slender, occurring singly, in pairs and in chains. Motile. Spores spherical, or nearly so, terminal, swelling rods. Gram-positive.

Gelatin: Liquefied.

Deep glucose agar colonies: Delicate, cottony flocculi. Only a trace of gas formed.

Broth: Turbid.

Litmus milk: May or may not coagulate and digest slowly (variable).

Indole formed in scarcely detectable trace. Odor of scatol.

Glucose is feebly fermented, with little gas. Lactose and sucrose not fermented.

Coagulated albumin: Rendered transparent, then slowly liquefied.

Grows well at 37°C.

Anaerobic.

Source: From human feces.

Habitat: Not determined, other than this source.

43. **Clostridium tetanomorphum** (Bulloch et al.) Bergey et al. (*Bacillus pseudo-tetanus*, Type No. IX,—Tetanus-like Bacillus (Pseudotetanus Bacillus), McIntosh and Fildes, Med. Res. Counc., Spec. Rept. Ser. No. 12, 1917, 11 and 32; *Bacillus tetanomorphus* Bulloch et al., Med. Res. Counc., Spec. Rept. Ser. No. 39, 1919, 41; *Macintoshillus tetanomorphus* Heller, Jour. Bact., *7*, 1922, 5; Bergey et al., Manual, 1st ed., 1923, 330; *Plectridium tetanomorphum* Prévot, Ann. Inst. Past., *61*, 1938, 87.) From Greek, shaped like the tetanus organism.

Synonyms or possibly related species: *Bacillus pseudotetani* Migula, Syst. d. Bakt., *2*, 1900, 598 (Tetanusähnlicher Bacillus and Pseudotetanusbacillus, Tavel and Lanz, Mitteil. a. klin. Med. Inst. d. Schweiz, *1*, 1893, 162; *Bacillus taveli*

Chester, Man. Determ. Bact., 1901, 304; *Plectridium pseudotetanicum* Prévot, Ann. Inst. Past., *61*, 1938, 87; *Plectridium pseudo-tetanicum* Prévot, Man. d. Class., etc., 1940, 158); possibly identical with *Bacillus fragilis* Veillon and Zuber, Arch. d. Méd. Expt. et d'Anat. Path., *10*, 1898, 536 and *Bacillus ramosus* Veillon and Zuber, *ibid.*, 537.

Rods: Slender, with rounded ends, occurring singly and in pairs, not in chains. Motile with peritrichous flagella. Spores spherical, or nearly so, terminal, swelling rods. Gram-positive.

Gelatin: Not liquefied. Gelatin is liquefied (Hall, Jour. Inf. Dis., *30*, 1922, 501).

Agar surface colonies (anaerobic): Small, flat, irregularly circular, translucent, crenated.

Deep agar colonies: Small, opaque, irregular; not woolly or branched.

Agar slant (anaerobic): Grayish, translucent growth.

Broth: Turbid.

Litmus milk: Unchanged; or occasional slight reduction of litmus.

Acid and gas from glucose and maltose. Fructose, galactose, lactose, sucrose, salicin, inulin, mannitol and glycerol not fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Egg-meat medium: Slight gas formation in 48 hours. White crystals are deposited.

Non-pathogenic for guinea pig and rabbit.

Grows at 30°C and 37°C.

Anaerobic.

Source: From war wounds and from soil.

Habitat: Not determined other than these sources. Probably rather common in soil.

44. **Clostridium alcaligenes** Bergey et al. (*Bacillus anaërobicus alcaligenes* Debono, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 232; Bergey et al., Manual, 1st ed., 1923, 331; *Palmula alcaligenes* Prévot, Ann. Inst. Past., *61*, 1938, 89; *Acuformis alcaligenes* Prévot, Man. d. Class., etc., 1940, 165.) From French *alcali*, alkali and Latin suffix, producing.

Rods: Long, slender, occurring singly, in pairs and in short chains. Non-motile. Spores spherical, terminal, swelling rods. Gram-positive.

Gelatin: Not liquefied.

Deep glucose agar colonies: Lenticular to irregular, or spherical, white, granular, entire.

Broth: Uniform turbidity. Fecal odor.

Milk: Alkaline; casein slowly precipitated, with yellowish supernatant fluid.

Indole is formed in abundance.

Acid and gas from glucose and lactose. Sucrose and dulcitol not fermented. Cultures have odor of valerianic acid.

Grows at 22°C and at 37°C.

Anaerobic.

Source: From human feces.

Habitat: Not determined, other than this source.

45. **Clostridium angulosum** (Distaso) Hauduroy et al. (*Bacillus angulosus* Distaso, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 439; not *Bacillus angulosus* Garnier and Simon, Bull. et Mem. Soc. Méd. Hôp. Paris, *24*, 1907, 1034; *Bacteroides angulosus* Bergey et al., Manual, 1st ed., 1923, 260; Hauduroy et al., Dict. des Bact. Path., 1937, 91.) From Latin *angulosus*, having angles, hooked.

Rods: Short, thick, with rounded ends, occurring singly and in pairs. Long rods sometimes bent to form an obtuse angle. Encapsulated. Non-motile. Spores very small, spherical, terminal, slightly swelling rods. Gram stain not recorded.

Plain gelatin: No growth at 20°C or at 37°C.

Glucose gelatin: Grows well at 37°C. Growth cloudy at first, then clears and liquefies, with whitish, powdery precipitate.

Glucose agar deep colonies: Large,

angular, opaque, yellowish. Gas bubbles are formed.

Broth: Turbid.

Litmus milk: Acid and coagulated in 14 days.

Indole is formed.

Acid and gas from glucose, lactose and sucrose. Butyric acid is formed.

Coagulated albumin not liquefied. Odor of skatol.

Optimum temperature 37°C.

Anaerobic.

Distinctive character: Resembles the Bacille neigeux, Jungano, Compt. rend. Soc. Biol., Paris, *62*, 1907, 677, in form, but not in other respects.

Source: From human feces.

Habitat: Not determined, other than this source.

46. **Clostridium putrefaciens** (McBryde) Sturges and Drake. (*Bacillus putrefaciens* McBryde, U. S. D. A., Bur. An. Ind., Bull. 132, 1911, 6; Sturges and Drake, Jour. Bact., *14*, 1927, 175; *Palmula putrefaciens* Prévot, Ann. Inst. Past., *61*, 1938, 89; *Acuformis putrefaciens* Prévot, Man. d. Class., etc., 1940, 165.) From Latin, putrefying.

Description from McBryde (*loc. cit.*) and amplified from Sturges and Drake (*loc. cit.*).

Rods: 0.5 to 0.7 by 3.0 to 15.0 microns, rounded ends, occurring singly, in pairs, and in chains and filaments. Non-motile. Spores spherical, terminal, swelling rods. Gram-positive.

Gelatin: Liquefied.

Agar surface colonies (anaerobic): Small, filamentous.

Agar slant (anaerobic): Scanty, white, beaded, glistening growth.

Broth: Moderate turbidity. Heavy, flocculent sediment.

Litmus milk: Rennet coagulation, peptonized. Litmus reduced.

Indole not formed.

Nitrites not produced from nitrates.

Slight production of hydrogen sulfide.

Acid and gas from glucose. Lactose, sucrose, maltose and starch not fermented.

Coagulated albumin liquefied.

Blood serum liquefied.

Brain medium blackened and slowly digested.

Minced pork medium: Slight disintegration; sour, putrefactive odor.

Non-pathogenic.

Optimum temperature 20°C to 25°C. Slow growth at 0°C and no visible growth at 37°C.

Anaerobic.

Source: From muscle tissue of hogs at slaughter.

Habitat: Not determined, other than this source.

47. **Clostridium nigrificans** Werkman and Weaver. (Iowa State Coll. Jour. Sci., *2*, 1927–28, 63; Werkman, Iowa State Coll. Research Bull. 117, 1929, 165.) From Latin *niger*, black and *faciens*, making.

Rods: 0.3 to 0.5 by 3.0 to 6.0 microns, with rounded ends. Motile. Spores oval, subterminal, slightly swelling rods. Gram-positive.

Gelatin: Not liquefied.

Deep agar colonies: Show blackening of medium around colonies. Black increased by adding 0.1 per cent ferric chloride to medium.

Milk: Not recorded.

Indole not formed.

Nitrites not produced from nitrates.

Glucose not fermented.

Carbohydrates not fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium blackened but not digested.

Hydrogen sulfide produced from cystine.

Non-pathogenic to man, guinea pig, mouse, rat and rabbit.

Optimum temperature 55°C. Thermophilic, growing at 65°C to 70°C.

Anaerobic.

Distinctive character: Black colonies in agar media.

Source: From canned corn showing sulfur stinker spoilage; also occasionally from soil and manure.

Habitat: Presumably soil, although detected with great difficulty.

48. **Clostridium belfantii** (Carbone and Venturelli) Spray. (*Bacillus belfantii* Carbone and Venturelli, Boll. Ist. Sieroter., Milan, 4, 1925, 59; not *Bacillus belfantii* Migula, Syst. d. Bakt., 2, 1900, 767; Spray, in Manual, 5th ed., 1939, 759; *Endosporus belfantii* Prévot, Ann. Inst. Past., *61*, 1938, 75.) Named for Belfanti, an Italian bacteriologist.

Rods: 0.4 to 0.6 by 1.5 to 7.0 microns, thick and straight, occurring singly, in pairs and in short chains. Motile. Spores large, oval, central to subterminal, swelling rods. Usually Gram-negative, occasional cells Gram-positive.

Granulose reaction negative

Gelatin: Not liquefied.

Plain agar surface colonies (anaerobic): Large, round, opaque, with filamentous edge.

Deep agar colonies: Arborescent along the stab. Gas is formed.

Plain broth: Diffuse turbidity, clearing by precipitation. No pigmentation. Gas is formed.

Potato mash: Forms a foam becoming violet in 24 to 48 hours, persisting 3 to 6 days, but disappearing on exposure to air.

Potato slant: Grayish pellicle, becoming violet in 24 to 48 hours. Gas of alcoholic odor is produced. No acetone.

Glycerinated potato: Thin, grayish pellicle, not becoming violet.

Milk: Coagulated in 24 to 48 hours. Clot broken by gas.

Milk agar: Abundant growth. Gas of butyric odor is liberated.

Indole is formed.

Hydrogen sulfide not formed.

Acid and gas from glucose, fructose, maltose, sucrose, lactose and mannitol. Starch and inulin weakly fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Grows well at 37°C.

Anaerobic.

Specifically agglutinated only by homologous antiserum.

Source: From retting beds and from air.

Habitat: Not determined, other than these sources.

Note: Six other strains of similar pigmenting, sporulating anaerobes are described by the authors. These have the general characters of *Clostridium belfantii*, but differ in certain particulars, such as color of pigment, fermentation and specific agglutination. Present information does not permit accurate systematic differentiation.

48a. *Clostridium maggiorai* (Carbone and Venturelli) Spray. (*Bacillus maggiorai* Carbone and Venturelli, *loc. cit.*, 59; Spray, in Manual, 5th ed., 1939, 759; *Endosporus maggiorai* Prévot, *loc. cit.*, 76.) Named for Maggiora, an Italian bacteriologist.

Characters in general those of the group, but does not produce indole.

Violet pigmentation persisting only 24 hours.

No alcoholic odor from cultures.

Specifically agglutinated only by homologous antiserum.

From mud from bed of stream in Italy.

48b. *Clostridium derossii* (Carbone and Venturelli) Spray. (*Bacillus de rossii* Carbone and Venturelli, *loc. cit.*, 59; Spray, in Manual, 5th ed., 1939, 760; *Endosporus rossii* Prévot, *loc. cit.*, 76.) Named for G. de Rossi, an Italian bacteriologist.

Characters in general those of the group. Greenish pigmentation on potato slant, changing to violet or orange.

Indole is formed.

Spedifically agglutinated only by homologous antiserum.

From soil in Italy.

48c. *Clostridium ottolenghii* (Carbone and Venturelli) Spray. (*Bacillus ottolenghii* Carbone and Venturelli, *loc. cit.*, 59; Spray, in Manual, 5th ed., 1939, 760;

Endosporus ottolenghii Prévot, *loc. cit.*, 76.) Named for Ottolenghi, an Italian bacteriologist.

Characters in general those of the group. Potato slant digested to a grayish-brown mash. Greenish pigment changing to reddish. Gas of disagreeable odor is formed.

Indole is formed.

Specifically agglutinated only by homologous antiserum.

From mud from bed of a stream in Italy.

48d. *Clostridium paglianii* (Carbone and Venturelli) Spray. (*Bacillus paglianii* Carbone and Venturelli, *loc. cit.*, 60; not *Bacillus paglianii* Trevisan, I generi e le specie delle Batteriacee, 1889, 19; Spray, in Manual, 5th ed., 1939, 760; *Endosporus paglianii* Prévot, *loc. cit.*, 76.) Named for Pagliani, an Italian bacteriologist.

Characters in general those of the group. One or two subterminal spores are said to be formed.

Greenish pigmentation on potato, browning with age.

Indole is formed.

Specifically agglutinated only by homologous antiserum.

From soil in Italy.

48e. *Clostridium lustigii* (Carbone and Venturelli) Spray. (*Bacillus lustigii* Carbone and Venturelli, *loc. cit.*, 59; not *Bacillus lustigii* Trevisan, *in litt.*, quoted from DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 958; not *Bacillus lustigi* Chester, Man. Determ. Bact., 1901, 304; Spray, in Manual, 5th ed., 1939, 760; *Endosporus lustigii* Prévot, *loc. cit.*, 76.) Named for Lustig, an Italian bacteriologist.

Characters in general those of the group. Green pigmentation on potato slant.

Indole is not formed.

Specifically agglutinated only by homologous antiserum.

From mud and soil in Italy.

48f. *Clostridium sclavoi* (Carbone and Venturelli) *comb. nov.* (*Bacillus sclavoi* Carbone and Venturelli, *loc. cit.*, 60; *Endosporus sclavoei* Prévot, *loc. cit.*, 76.) Named for Sclavo, an Italian bacteriologist.

Characters in general those of the group. Greenish to brown pigmentation on potato slant.

Indole is not formed.

Specifically agglutinated only by homologous antiserum.

From retting flax in Italy.

49. **Clostridium venturelli** (de Tomasi) Spray. (*Bacillus venturelli* de Tomasi, Boll. Ist. Sieroter. Milanese, *4*, 1925, 203; *Endosporus venturelli* Prévot, Ann. Inst. Past., *61*, 1938, 76; Spray, in Manual, 5th ed., 1939, 769.) Named for Venturelli, an Italian bacteriologist.

Rods: Pleomorphic, fusiform to straight or slightly curved, with rounded ends. Size variable with medium, 0.5 to 0.8 by 2.5 to 8.0, and up to 20.0 microns. Occurring singly, in pairs, in chains, or frequently in parallel groupings. Motile. Capsulated. Spores oval, central to excentric, swelling rods. Gram-negative.

Granulose reaction positive; showing violet granules with iodine.

Gelatin: No growth; no liquefaction.

Glucose agar surface colonies (anaerobic): Round, becoming rose-colored.

Plain agar slant (anaerobic): No growth.

Maltose agar stab: Colonies lenticular, yellowish, turning to rose. Odor of acetone.

Plain broth: No growth.

Potato slant (anaerobic): Becomes mucilaginous. Bubbles of gas of amylic odor.

Potato mash: Very abundant growth; rose color, with red spots.

Milk with $CaCO_3$: Coagulated; becoming yellow, then pale rose. Amylic odor.

Acid and gas from glucose, maltose, sucrose, fructose, lactose, inositol, dextrin and starch. Arabinose, glycerol, mannitol and inulin not fermented (cited from Weinberg et al., Les Mic. Anaér., 1937, 800).

Fermentation products include especially acetone and amyl alcohol, and smaller amounts of propyl, butyl and isobutyl alcohols, and acetic acid.

Coagulated albumin not digested.

Blood serum not liquefied; forms a small amount of yellowish liquid.

Optimum temperature 18°C to 20°C. Inhibition of growth and pigmentation above 25°C.

Anaerobic.

Distinctive character: Forms a rose-colored pigment which is soluble in alcohol, but not in water, ether or chloroform.

Source: From potato.

Habitat: Not determined, other than this source.

50. **Clostridium roseum** McCoy and McClung. (Arch. f. Mikrobiol., *6*, 1935, 237.) From Latin *roseum*, pink.

Rods: 0.7 to 0.9 by 3.2 to 4.3 microns, occurring singly, in pairs and in short chains. Motile with peritrichous flagella. Spores oval, subterminal, swelling rods to clostridia. Gram-positive, becoming Gram-negative.

Granulose reaction positive in clostridial stage.

Glucose gelatin: Liquefied.

Plain agar slant (anaerobic): Surface growth scant, scarcely perceptible.

Glucose agar surface colonies (anaerobic): Raised, smooth, edges slightly irregular. Pink to orange pigment.

Deep glucose agar colonies: Compact, lenticular, pink to red-orange.

Blood agar not hemolyzed.

Pigmentation (anaerobic): Colonies red-orange, becoming purplish-black on aeration.

Plain broth: No growth.

Glucose broth: Abundant, uniform turbidity, with much gas.

Litmus milk: Stormy coagulation. Litmus reduced, but obscured by pink pigment. Clot slowly softened. Proteolysis demonstrable on milk agar.

Potato: Rapid digestion to a clear yellow fluid and bluish sediment. Much gas with butylic odor.

Corn mash: Resembling reaction of *Clostridium acetobutylicum*, but with flesh-orange pigment, becoming slowly purple at surface on ageing.

Hydrogen sulfide formed from thiosulfate and sulfite.

Nitrates reduced to ammonia.

Nitrites reduced to ammonia.

Indole not formed.

Acid and gas from xylose, arabinose, glucose, mannose, fructose, galactose, lactose, maltose, sucrose, raffinose, starch, dextrin, glycogen, inulin, pectin and salicin. Esculin and amygdalin weakly fermented. Mannitol, erythritol, glycerol, α-methyl glucoside, Ca-lactate and cellulose not fermented.

Coagulated albumin cubes: Softened and yellowed by slow digestion.

Blood serum not liquefied.

Brain medium not blackened or digested.

Non-pathogenic for guinea pig and rabbit.

Optimum temperature about 37°C. Growth occurs from 8°C to 62°C.

Anaerobic.

Source: From German maize.

Habitat: Probably occurs in soil.

51. **Clostridium chromogenes** Prévot. (Chromogenic anaerobe, Ghon and Mucha, Cent. f. Bakt., I Abt., Orig., *42*, 1906, 406; *Bacillus anaerobius chromogenes* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., 1914, 321; Prévot, Ann. Inst. Past., *61*, 1938, 85.) From Latin, color-producing.

Rods: Moderate size, coccoid to elongate, ends rounded to slightly pointed; straight to slightly curved. Occurring singly, paired, in short chains and in long, curved to coiled filaments. Capsulate, especially in serum media. Motile, with many peritrichous flagella. Spores abundant, oval, central, subterminal, to apparently terminal at maturation, swelling rods to clubs and clostridia. Gram-positive.

Granulose negative with iodine solution.

Gelatin: Liquefied in 48 hours. Diffuse turbidity, clearing with abundant, whitish-gray sediment, which later becomes red to violet-red. Upper (1 cm) layer shows diffuse, red pigment.

Deep plain agar (without peptone): Growth sparse. Pigment not formed in absence of peptone.

Blood agar surface colonies (anaerobic): Grayish, moist, shining, flat; edges lobate with finely dendritic-tufted edges. Blood agar is hemolyzed.

Glucose agar surface colonies (anaerobic): As on blood agar. Growth slightly less profuse.

Glucose agar deep colonies: Grayish-white, multi-lobate, with dense center and dendritic, tufted edges. Growth begins about 1 cm below surface. Gas abundantly formed. Diffuse, red pigment appears in superficial layers after 4 to 5 days.

Glucose meat-infusion broth: Abundant, diffuse turbidity with much gas. Gradual, profuse sedimentation, but with prolonged turbidity.

Peptone water: Growth variable; sometimes fails. At best, moderate turbidity and sediment. No gas.

Synthetic fluid media (Uschinsky, etc.): No growth (unless peptone is added). Growth is proportionate to added peptone.

Potato slant (anaerobic): Growth delicate, shining, grayish-yellow. Fecal odor.

Milk: Spongy coagulation after 3 to 4 days. Abundant gas. Turbid, yellowish whey is expressed. Casein clot gradually digested in 4 to 5 weeks. Fecal odor.

Indole is not formed.

Hydrogen sulfide is abundantly formed.

Coagulated albumin (hydrocoel- and ascitic-fluid): Digested and blackened, with moderate gas of fecal odor. When covered with agar, the agar plug shows diffuse, red pigmentation.

Pathogenicity: Weakly pathogenic for white mice and guinea pigs. Produces hemorrhagic, serous peritonitis after intraperitoneal inoculation. Death due apparently to a weak toxin. Virulence increased by animal passage.

Grows well at 21°C and at 37°C.

Anaerobic.

Distinctive character: Red pigmentation which is increased on addition of chlorine-, or of bromine-water. Although produced by an anaerobe, pigment appears only in aerated zone and depends on peptone content of medium.

Source: From pus of a human perinephritic abscess.

Habitat: Not determined, other than this single source.

52. **Clostridium felsineum** (Carbone and Tombolato) Bergey et al. (*Bacillus felsineus* Carbone and Tombolato, Le Staz. Sper. Agrar., Ital., *50*, 1917, 563; Ruschmann and Bavendamm, Cent. f. Bakt., II Abt., *64*, 1925, 340; Van der Lek, Thesis, Delft, 1930, (143?); *Clostridium felsinus* Bergey et al., Manual, 3rd ed., 1930, 453.) Named for Felsinea, the ancient name of Bologna, Italy.

Described from Ruschmann and Bavendamm (*loc. cit.*), from the Kluyver strain used by Van der Lek (*loc. cit.*), and from McCoy and McClung, Arch. f. Mikrobiol., *6*, 1935, 230.

Rods: 0.3 to 0.4 by 3.0 to 5.0 microns, occurring singly, in pairs and in short chains. Motile with peritrichous flagella. Spores oval, subterminal, swelling rods to clostridia. Gram-positive, becoming Gram-negative.

Granulose positive in the clostridial stage.

Glucose gelatin: Liquefied.

Plain agar slant (anaerobic): Surface growth scant, scarcely perceptible.

Glucose agar surface colonies (anaerobic): Raised, smooth, slightly irregular, yellow-orange.

Deep glucose agar colonies: Compact, lenticular, opaque, yellow.

Blood agar not hemolyzed.

Pigmentation (anaerobic): Yellow-orange, ageing to brownish. Not changing on aeration.

Plain broth: No growth.

Glucose broth: Abundant, uniform turbidity, with much gas. Yellow slimy sediment.

Litmus milk: Acid and coagulation. Litmus reduced. Clot torn and yellowed. No visible digestion.

Potato: Digested to a yellow slime. Much gas with butylic odor.

Corn mash: Resembling reaction of *Clostridium acetobutylicum*, but with flesh to orange pigment.

Indole not formed.

Nitrates reduced to ammonia.

Nitrites reduced to ammonia.

Acid and gas from arabinose, xylose, glucose, mannose, fructose, galactose, lactose, maltose, sucrose, raffinose, starch, dextrin, inulin, glycogen, pectin and salicin. Mannitol, erythritol, glycerol, Ca-lactate and cellulose not fermented.

Fermentation products include butyl and ethyl alcohol, acetone, organic acids (probably butyric and acetic), H_2 and CO_2.

Coagulated albumin cubes: Softened and yellowed by slow digestion.

Blood serum not liquefied.

Brain medium not blackened or digested.

Non-pathogenic for guinea pig and rabbit.

Grows at 37°C.

Anaerobic.

Source: From retting flax.

Habitat: Not determined. Found in soil in Italy, Argentina and in the United States.

53. **Clostridium carbonei** Arnaudi. (Soc. Intern. Microbiol., Boll. Sez. Ital., *8*, 1936, 251, and Boll. Ist. Sieroter, Milano, *16*, 1937, 650; *Inflabilis carbonei* Prévot, Man. d. Class., etc., 1940, 96.) Named for Carbone, an Italian bacteriologist.

Rods: 0.8 to 1.0 by 3.5 to 4.5 microns, with ends slightly tapered. Non-motile. Spores oval, terminal, 0.8 to 1.0 by 1.0 to 1.75 microns, swelling rods. Gram-positive.

Granulose reaction strongly positive with iodine solution.

Gelatin: No growth.

Glucose and lactose gelatin: No growth.

Plain agar surface colonies (anaerobic): Flat, shining, colorless, with irregular edges.

Malt agar surface colonies (anaerobic): Creamy to slightly reddish colonies with irregular edges.

Roux-potato slant (anaerobic): Punctiform, raised, opaque, deep red colonies, becoming almost violet.

Plain agar stab: Only traces of growth along stab.

Glucose and maltose agar stab: No growth.

Plain broth: Very slight, colorless, diffuse turbidity.

Glucose broth: Very slight turbidity.

Maltose broth: Intense turbidity, with profuse, reddish-yellow sediment.

Tarozzi broth: Slight, diffuse turbidity.

Indole not formed.

Hydrogen sulfide not formed.

Milk: Soft coagulation, with slight, fine reddish flocculence. Whey turbid and colorless. Reaction acid. Clot not digested.

Digest-milk (optimum medium): Very abundant turbidity, with bright red flocculent sediment, diffusing uniformly on shaking.

Coagulated egg-yolk broth: Slight turbidity; no digestion.

Coagulated egg-albumin broth: Slight turbidity; no digestion.

Coagulated serum (Loeffler, anaerobic): Poor growth; flat, red surface colonies. No digestion.

Brain medium: Not recorded.

Cellulose not attacked. Hemp is not retted.

Ferments weakly: Glucose, maltose, sucrose, galactose, fructose and raffinose. Slow and partial fermentation of lactose (only in acidified medium). Starch slightly fermented. Fermentation products include H_2, CO_2, CH_4, butyric acid and traces of ethyl alcohol.

Non-pathogenic for sheep, rabbit, guinea pig or white mouse.

Optimum reaction pH 7.0 to 7.2; minimum pH 6.0; maximum pH 8.0.

Optimum temperature 37°C. Grows slowly at 25°C to 30°C; growth ceases at 40°C.

Anaerobic.

Distinctive character: Production of a brilliant red pigment, soluble in amyl alcohol, petrol-ether, xylol and aniline oil. Partly soluble in ether, chloroform and acetone. Pigment very stable in light.

Source: From macerated raw potato infusion.

Habitat: Not recorded, other than from this single source.

54. **Clostridium spumarum** (Prévot and Pochon) *comb. nov.* (*Plectridium spumarum* Prévot and Pochon, Compt. rend. Soc. Biol., Paris, *130*, 1939, 966.) From Latin, foam or froth.

Rods: 0.5 by 4.0 microns, motile. Spores are oval and terminal, swelling rods. Gram-positive.

Gelatin: Liquefied in 15 days.

Deep agar: Forms small cottony colonies and a few gas bubbles.

Peptone water: Turbidity and slight sediment.

Milk: Coagulated in 5 days, but clot is not digested.

Indole is produced.

Hydrogen sulfide is formed (medium not stated).

Sugars not attacked immediately after isolation.

After 1 month cultivation, ferments slowly glucose, fructose, galactose, maltose, arabinose, xylose, sucrose, mannitol and starch. Inulin is not fermented.

Cellulose (in synthetic medium) is fermented chiefly to acetic and butyric acids, together with inflammable gas and traces of ethyl alcohol.

Coagulated albumin not attacked.

Brain medium not blackened.

Optimum temperature around 37°C. Not thermopbilic.

Anaerobic.

Distinctive characters: Does not produce pigment, and ferments a variety of carbohydrates.

Source: From the scum of sugar refining vats.

Habitat: Not determined, other than from this source.

55. **Clostridium werneri** Bergey et al. (*Bacillus cellulosam fermentans* Werner, Cent. f. Bakt., II Abt., *67*, 1926, 297; Bergey et al., Manual, 3rd ed., 1930, 452; *Bacterium cellulosam* Jepson, Bull. Entomol. Res., *28*, 1937, 163; *Terminosporus cellulosam fermentans* Prévot, Ann. Inst. Past., *61*, 1938, 86; *Terminosporus cellulosam-fermentans* Prévot, Man. d. Class., etc., 1940, 148.) Named for Erich Werner, the German bacteriologist who first isolated this organism.

Related species: Probably closely related to *Clostridium omelianskii*.

Rods: 0.5 to 0.7 by 1.5 to 7.0 microns, occurring singly and in pairs, but not in chains. Motile with peritrichous flagella. Spores oval, terminal, swelling rods. Gram-negative.

Cellulose agar slant (anaerobic): Growth only in contact with cellulose. Growth grayish-black; agar is darkened. Gas is formed.

Agar slant (anaerobic): No growth.

Broth: No growth.

Broth with filter paper: Poor growth; cellulose weakly attacked.

Omelianski solution with filter paper: Abundant growth; cellulose digested with formation of H_2 and CO_2.

Hydrogen sulfide is formed in the Omelianski medium, presumably from the $(NH_4)_2SO_4$ and $MgSO_4$.

Glucose not fermented.

Carbohydrates, other than cellulose, not fermented.

Non-pathogenic for mice.

Optimum temperature 33°C to 37°C.

Anaerobic.

Source: From larvae of rose leaf beetle (*Potosia cuprea*).

Habitat: Occurs in soil and in feces of herbivorus animals.

56. **Clostridium cellulosolvens** Cowles and Rettger. (Jour. Bact., *21*, 1931, 167; *Caduceus cellulosolvens* Prévot, Ann. Inst. Past., *61*, 1938, 86.) From chemical term, cellulose, and Latin, dissolving.

Rods: 0.5 by 2.0 to 6.0 microns, commonly curving, occurring singly and in pairs, not in chains. Non-motile. Spores spherical, terminal, swelling rods. Gram stain uncertain; usually Gram-negative.

Does not grow in routine media, except where cellulose or certain few carbohydrates are added.

Surface colonies on dextrin-cysteine meat infusion agar (anaerobic): Tiny, round, transparent dew-drops; finely granular, with smooth edge.

Acid and gas from cellulose, dextrin, arabinose, xylose and soluble starch. Glucose, fructose, mannose, lactose, maltose, sucrose, melezitose, raffinose, inulin, salicin, amygdalin, adonitol, dulcitol, erythritol, glycerol, inositol, mannitol, sorbitol and gum arabic not fermented.

Cellulose decomposed to H_2, CO_2 and organic acids.

Grows at 37°C.

Anaerobic.

Source: From horse feces.

Habitat: Not determined, other than this source. Probably widely dispersed in manured soil.

57. **Clostridium dissolvens** Bergey et al. (*Bacillus cellulosae dissolvens* Khouvine, Ann. Inst. Past., *37*, 1923, 711; Bergey et al., Manual, 2nd ed., 1925, 344; *Caduceus cellulosae dissolvens* Prévot, Ann. Inst. Past., *61*, 1938, 86.) From Latin, dissolving.

Rods: Slender, ranging from 2.5 to 12.5 microns in length, occurring singly, occasionally in pairs, but not in chains. Non-motile. Spores oval, terminal, swelling rods. Gram-negative.

Cellulose is digested by the formation of an endocellulase which acts only when the bacteria are attached to the cellulose. Saccharides are formed from cellulose, also CO_2, H_2, ethyl alcohol, acetic, lactic and butyric acids.

A yellow pigment is formed in presence of cellulose.

Glucose not fermented.

Carbohydrates, other than cellulose, not fermented.

Non-pathogenic for guinea pig.

Optimum temperature: Grows between 35°C and 51°C, without a definite optimum.

Anaerobic.

Distinctive character: Grows only in media containing cellulose, in the presence of which it produces a yellow pigment.

Source: From human feces.

Habitat: Intestinal canal of man.

58. **Clostridium omelianskii** (Henneberg *emend.* Clausen) *comb. nov.* (Cellulose fermenting microbe, Omelianski, Compt. rend. Acad. Sci., Paris, *121*, 1895, 653 (*Bacillus fermentationis cellulosae* Omelianski, Arch. Sci. Biol. (Russ.), *7*, 1899, 419; *Bacterium cellulosis* Migula, Syst. d. Bakt., *2*, 1900, 513); Bacille hydrogénique, Omelianski, Arch. Sci. Biol. (Russ.), *9*, 1902–03, 263 (Wasserstoffbacillus, Omelianski, Cent. f. Bakt., II Abt., *8*, 1902, 262; *Bacillus fossicularum* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 466; *Bacillus hydrogenii* Jungano and Distaso, Les Anaérobies, 1910, 147; *Bacillus omelianskii* Henneberg, Cent. f. Bakt., II Abt., *55*, 1922, 276, *emend.* Clausen, Cent. f. Bakt., II Abt., *84*, 1931, 40 and 54; *Omelianskillus hydrogenicus* Heller, Jour. Bact., *7*, 1922, 5; *Caduceus cellulosae hydrogenicus* Prévot, Ann. Inst. Past., *61*, 1938, 86); Bacille formenique, Omelianski, Arch. Sci. Biol. (Russ.), *9*, 1902–03, 263 (Methanbacillus, Omelianski, Cent. f. Bakt., II Abt., *11*, 1903–04, 370; *Bacillus methanigenes* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 466; *Cellobacillus methanigenes* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 343; *Bacillus methanii* Jungano and Distaso, Les

Anaérobies, 1910, 146; *Caduceus cellulosae hydrogenicus* var. *cellulosae methanicus* Prévot, Ann. Inst. Past., *61*, 1938, 86; *Caduceus cellulosae methanicus* Prévot, Man. d. Class., etc., 1940, 150).) Named for Omelianski, the Russian bacteriologist who first described this type.

This species was apparently first isolated and studied in pure culture by Clausen (*loc. cit.*). From his studies he concludes that Omelianski's Wasserstoff- and Methanbacillus are but a single species, and that the gaseous fermentation products (H_2, CO_2 and CH_4) were affected by the symbiotic forms always present in Omelianski's cultures.

His evidence is quite convincing, and the organism is presented here from his description.

Rods: Length varying with the medium, 0.5 to 0.7 by 5.0 to 15.0 microns, straight to slightly curved. Occurring chiefly singly, occasionally in pairs, frequently parallel in groups, never in chains or filaments. Young cells motile, but motility disappearing with sporulation. Flagella not demonstrable. Spores spherical, terminal, swelling rods. Spores 1.0 to 1.5 microns in diameter, varying with medium. Gram-positive, becoming Gram-labile on sporulation.

Young vegetative cells colored wine-red with iodine solution.

Gelatin (plus asparagine): Liquefied in 6 to 10 days. Medium remains perfectly clear.

Asparagine agar deep colonies: Grayish-white, delicate, cottony, with fine radial outgrowths.

Asparagine agar surface colonies (anaerobic): Poor growth, delicate, translucent, filmy, scarcely discernible.

Cellulose-liver broth: Solution remains visibly clear and does not darken with age. Occasional large gas bubbles arise.

Indole not formed.

Ammonia not formed.

Nitrates not reduced to nitrites.

Traces of H_2S produced in inorganic solutions.

Milk: Soft coagulation in 24 hours. Amorphous clot shrinks and settles, forming a yellowish-red to orange sediment, with turbid supernatant whey.

Brain medium: Not digested or blackened; no visible evidence of growth.

None of the following carbohydrates attacked: Maltose, mannitol, lactose, glucose, sucrose, galactose, fructose, starch, salicin, glycerol and inulin.

Cellulose apparently the primary C-source, but is only weakly attacked by pure cultures.

Yellow pigment not recorded in presence of cellulose (see *Clostridium dissolvens*).

Non-pathogenic for mice; other animals not recorded.

Optimum reaction pH 7.0 to 7.4; grows between pH 6.0 and 8.4.

Optimum temperature 37°C to 42°C.

Anaerobic: Growing at 25 to 30 mm mercury pressure.

Distinctive characters: Ability to liquefy gelatin (plus asparagine); to coagulate milk with orange sediment, and to grow in media containing asparagine without requiring presence of cellulose. Spores resist heating at 100°C for 90 minutes.

Source: From human, cow and horse excreta, from cow's stomach contents, from cheese and from soil.

Habitat: Intestinal canal of animals, and presumably thence widely disseminated in soil.

59. **Clostridium carnis** (Klein) Spray. (Art V, von Hibler, Cent. f. Bakt., I Abt., *25*, 1899, 515; *Bacillus carnis* Klein, Cent. f. Bakt., I Abt., Orig., *35*, 1904, 459, also Trans. Path. Soc., London, *55*, 1904, 74; Art. VI, von Hibler, Untersuch. ü. d. Path. Anaer., 1908, 3 and 406; *Hiblerillus sextus* Heller, Jour. Bact., *7*, 1922, 6; *Bacillus lactiparcus* Lehmann and Süssmann, in Lehmann and Neumann, Bakt. Diag., 7 Aufl., *2*, 1927, 647; *Plectridium carnis* Prévot, Ann. Inst. Past., *61*, 1938, 87; Spray, in Bergey et al., Manual, 5th ed., 1939, 750; *Clostridium*

sextum Prévot, Man. d. Class., etc., 1940, 136.) From Latin, of flesh.

Description from Hall and Duffett, Jour. Bact., *29*, 1935, 269.

Rods: 0.5 to 0.7 by 1.5 to 4.5 microns, occurring singly, in pairs, rarely in chains of 3 to 4 cells. Motile with peritrichous flagella. Spores oval to elongate, subterminal, slightly swelling rods. Gram-positive.

Gelatin: Not liquefied or blackened.

Agar surface colonies (aerobic): Minute, transparent dew-drops, becoming flat and lobate.

Blood agar surface colonies (aerobic): Similar to plain agar. Slight hemolysis.

Deep agar colonies: Lenticular, becoming nodular to arborescent.

Milk: Abundant gas, but no coagulation or other change.

Indole not formed.

Acid and gas from glucose, galactose, fructose, maltose, lactose, sucrose, amygdalin, salicin and dextrin. Trehalose, raffinose, xylose, arabinose, starch, inulin, mannitol, dulcitol, sorbitol, glycerol and inositol not fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Pathogenic for guinea pig, white rat and rabbit. Forms an exotoxin of moderate intensity, producing edema, necrosis and death on sufficient dosage.

Grows well at both 37°C and at room temperature.

Anaerobic and microaerophilic; growing delicately on aerobic agar slants.

Source: Originally isolated from a rabbit inoculated with garden soil (von Hibler); from contaminated beef infusion (Klein).

Habitat: Probably occurs in soil.

60. **Clostridium histolyticum** (Weinberg and Seguin) Bergey et al. (*Bacillus histolyticus* Weinberg and Seguin, Compt. rend. Acad. Sci., Paris, *163*, 1916, 449; *Weinbergillus histolyticus* Heller, Jour. Bact., *7*, 1922, 9; Bergey et al., Manual, 1st ed., 1923, 328.) From Greek, tissue-dissolving.

Rods: 0.5 to 0.7 by 3.0 to 5.0 microns, occurring singly and in pairs. Motile with peritrichous flagella. Spores oval, subterminal, swelling rods. Gram-positive.

Gelatin: Complete liquefaction in 24 hours.

Blood agar surface colonies (aerobic): Minute, round dew-drops. Blood is hemolyzed.

Deep agar colonies: Variable; from lenticular, lobate, to fluffy, according to the agar concentration.

Agar slant (aerobic): Grows aerobically in barely perceptible film, or in tiny, smooth, discrete colonies.

Broth: Turbid, with slight precipitate.

Indole not formed.

Nitrites not produced from nitrates.

Litmus milk: Softly coagulated, then slowly digested. Little gas is formed.

Carbohydrates are not fermented.

Coagulated albumin slowly liquefied.

Blood serum slowly liquefied with darkened, putrid fluid.

Brain medium blackened and digested with putrefactive odor.

Egg-meat medium: Little gas is formed. Meat first reddened, then darkened in 3 days. Digestion apparent in about 24 hours. Nauseous odor. Tyrosin crystals are abundant after about a week.

Pathogenic for small laboratory animals. Produces a cytolytic exotoxin which causes extensive local necrosis and sloughing on injection. Not toxic on feeding.

Grows well at 37°C.

Anaerobic and microaerophilic. Grows feebly on aerobic agar slant.

Source: Originally isolated from war wounds, where it induces active necrosis of tissue.

Habitat: Not determined, other than source stated. Found occasionally in feces and soil. Apparently widely, but sparsely, dispersed in soil.

61. **Clostridium tertium** (Henry) Bergey et al. (*Bacillus tertius* Henry, Jour. Path. and Bact., *21*, 1916, 347; *Henrillus tertius* Heller, Jour. Bact., *7*, 1922, 5; Bergey et al., Manual, 1st ed., 1923, 332; *Plectridium tertium* Prévot, Ann. Inst. Past., *61*, 1938, 87.) From Latin *tertius*, third.

Probable synonyms: *Bacillus gazogenes parvus* Choukévitch, Ann. Inst. Past., *25*, 1911, 271 (*Bacillus gazogenes* Choukévitch, *ibid.*, 268; *Plectridium gazogenes* Prévot, Ann. Inst. Past., *61*, 1938, 87); Bacillus Y, Fleming, Lancet, *2*, 1915, 376; *Bacillus aero-tertius* Bulloch et al., Med. Res. Counc., Spec. Rept. Ser. 39, 1919, 4; *Bacillus spermoide* Ninni, Pathologica, *21*, 1920, 385 (*Clostridium spermoides* Bergey et al., Manual, 1st ed., 1923, 336; *Palmula spermoides* Prévot, Ann. Inst. Past., *61*, 1938, 88; *Acuformis spermoides* Prévot, Man. d. Class., etc., 1940, 164).

Rods: 0.4 to 0.6 by 3.0 to 6.0 microns, occurring singly and in pairs, not in chains. Motile. Spores oval, terminal, swelling rods. Gram-positive.

Gelatin: Not liquefied.

Agar surface colonies (aerobic): Circular with opalescent, crenated margin.

Deep agar colonies: Small, lenticular, regular, smooth.

Agar slant (aerobic): Grayish, filmy, opalescent growth.

Blood agar is hemolyzed.

Broth: Turbid, with sediment.

Litmus milk: Acid, coagulated, with some gas formation. Clot is not digested.

Indole not formed.

Nitrites produced from nitrates.

Acid and gas from glucose, fructose, galactose, mannose, lactose, maltose, sucrose, arabinose, xylose, trehalose, melezitose, soluble starch, esculin, mannitol, inositol and salicin. Inulin and glycerol not fermented.

Coagulated albumin not liquefied.

Blood serum not liquefied.

Brain medium not blackened or digested.

Meat medium reddened; acid and gas formed. Meat not blackened or digested. Non-putrefactive.

Non-pathogenic for guinea pig and rabbit.

Optimum temperature 30°C to 35°C. Can grow at 50°C.

Anaerobic and microaerophilic. Grows feebly on aerobic agar slant.

Source: From gangrenous wounds and from feces.

Habitat: Widely distributed in soil, feces and sewage.

Appendix I: The following species of anaerobes are listed, chiefly for their historic interest, from descriptions too incomplete to permit present definite classification. Many of these original cultures are now lost, and the descriptions are often too brief even to permit comparison with recognized species. Several were described from cultures of doubtful purity, and even the anaerobic status of some is open to question. The synonymy cited is not to be regarded as definitely established in all instances.

Many strains have been described by number or by common names only. These are not included here, but many may be found listed in Les Microbes Anaérobies, Weinberg, Nativelle and Prévot, Paris, 1937, and in The Anaerobic Bacteria and their Activities in Nature and Disease, McCoy and McClung, Univ. Calif. Press, 1939.

Species are listed alphabetically under the first valid binomial, regardless of their original designation.

Acuformis caninus Prévot. (Unnamed species of Wolbach and Saiki, Jour. Med. Res., *21*, 1909, 267; *Palmula canina* Prévot, Ann. Inst. Past., *61*, 1938, 88; Prévot, Man. d. Class., etc., 1940, 164.) From liver of healthy dog.

Acuformis dubitatus Prévot. (Species No. 1 of Rodella, Cent. f. Bakt., II Abt., *17*, 1907, 374; *Palmula dubitata* Prévot, Ann. Inst. Past., *61*, 1938, 89; Prévot, Man. d. Class., etc., 1940, 165.) From normal and from spoiled milk.

Acuformis immobilis Prévot. (*Bacillus putrificus immobilis* Distaso, Ann. Inst. Past., *23*, 1909, 955; *Palmula immobilis* Prévot, Ann. Inst. Past., *61*, 1938, 89; Prévot, Man. d. Class., etc., 1940, 165.) From intestine of the flying fox (*Pteropus*).

Amylobacter butylicus Duclaux. (Ann. Inst. Past., *9*, 1895, 813.) From fermenting macerated potato inoculated with soil.

Amylobacter ethylicus Duclaux. (Ann. Inst. Past., *9*, 1895, 814.) Probably only a facultative anaerobe. From fermenting macerated potato inoculated with soil.

Bacillus acidi acetici Thöni. (Thesis, Bern, 1906, (?); quoted from McCoy and McClung, The Anaer. Bact. etc., *2*, 1939, 413.) Source not known.

Bacillus aerogenes gangrenosae Weinberg and Ginsbourg. (Bacillo aerogene gangrenosa, Nacciarone, Riforma Med., *33*, 1917, 778; Weinberg and Ginsbourg, Bull. Inst. Past., *23*, 1925, 825.) From human gaseous gangrene.

Bacillus amyloclasticus Renshaw and Fairbrother. (*Bacillus amyloclasticus intestinalis* Renshaw and Fairbrother, Brit. Med. Jour., *1*, 1922, 675; *ibid.*, 818.) Stated by authors to be a facultative anaerobe. From intestine of diabetic persons.

Bacillus anaerobic No. VIII Chester. (Anaerobe No. VIII, Sanfelice, Ztschr. f. Hyg., *14*, 1893, 375; Pseudo-Rauschbrand-bacillus, Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 250; Chester, Man. Det. Bact., 1901, 296.) From putrefying meat infusions, soil, and from tissues of guinea pigs after inoculation with soil.

Bacillus butyricus Botkin. (Botkin, Ztschr. f. Hyg., *11*, 1892, 421; Bacillus No. I, Flügge, Ztschr. f. Hyg., *17*, 1894, 290; *Bacillus botkini* Migula, Syst. d. Bakt., *2*, 1900, 594; *Bacillus parabutyricus* LeBlaye and Guggenheim, Man. Prat. de Diag. Bact., 1914, 324; not *Bacillus parabutyricus* Gratz and Vas, Cent. f. Bakt., II Abt., *41*, 1914, 510; *Clostridium butyricum* Holland, Jour. Bact., *5*, 1920, 217 and 222.) From milk.

Bacillus butyricus dimorphus Rocchi. (Cent. f. Bakt., I Abt., Orig., *60*, 1911, 580.) A collective name for a group of butyric anaerobes considered denaturable and mutually interconvertible.

Bacillus cadaveris grandis Sternberg. (Researches relating to the etiology and prevention of yellow fever, Washington, 1891, 213.) From liver of a yellow fever cadaver.

Bacillus cannabinus Makrinow and Tchijowa. (Arch. Sci. Biol. (Russ.), *29*, 1929, 52; also Cent. f. Bakt., II Abt., *80*, 1930, 59.) Stated by the authors to be a facultative anaerobe. From soil and from retting of kenaf (*Hibiscus cannabinus*).

Bacillus cincinnatus Gerstner. (Gerstner, Thesis, Basel, 1894, 17; *Bacillus cincinnati* Jungano and Distaso, Les Anaérobies, 1910, 88.) From soil and sewage.

Bacillus clavatus Migula. (Anaerobe No. III, Flügge, Ztschr. f. Hyg., *17*, 1894, 289; Migula, Syst. d. Bakt., *2*, 1900, 597; *Bacillus cuneatus* Chester, Man. Determ. Bact., 1901, 299.) From boiled cow's milk.

Bacillus colicogenes Tissier. (Ann. Inst. Past., *26*, 1912, 523.) From stool of an infant with diarrhea and colic.

Bacillus coprogenes Hopffe. (*Bacillus coprogenes foetidus* Herfeldt, Cent. f. Bakt., II Abt., *1*, 1895, 77; not *Bacillus coprogenes foetidus* Flügge, Die Mikroorg., 2 Aufl., 1886, 305; Hopffe, Ztschr. Infkrnkh. u. Hyg. Haust., *14*, 1913, 404.) From manure and from horse intestine.

Bacillus cresologenes Rhein. (Rhein, Compt. rend. Soc. Biol., Paris, *87*, 1922, 576; *Clostridium cresologenes* Prévot, Ann. Inst. Past., *61*, 1938, 85.) From brain medium inoculated with soil.

Bacillus de baryanus Klein. (Ber. d. Deuts. Bot. Gesellsch., 7 (Bhft.), 1889, 60.) Migula (Syst. d. Bakt., *2*, 1900, 640) says this is probably anaerobic. Observed in swamp water, but not cultivated on artificial media.

Bacillus diffrangens Gerstner. (Thesis, Basel, 1894, 19.) From soil and sewage.

Bacillus dimorphobutyricus Lehmann and Neumann. (Dimorpher Buttersäurebacillus, Grassberger and Schattenfroh, Arch. f. Hyg., *60*, 1907, 59; Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 441.) From milk.

Bacillus elegans Romanovitch. (Compt. rend. Soc. Biol., Paris, *71*, 1911, 169.) From normal human intestine and from diseased appendix.

Bacillus fibrosus Gerstner. (Thesis, Basel, 1894, 26.) From soil and sewage.

Bacillus flüggei Migula. (Anaerobe No. IV, Flügge, Ztschr. f. Hyg., *17*, 1894, 290; Migula, Syst. d. Bakt., *2*, 1900, 597.) From boiled cow's milk.

Bacillus fossicularum Lehmann and Neumann. (Wasserstoffbacillus, Omelianski, Cent. f. Bakt., II Abt., *8*, 1902, 262; Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 466, may have been named in the 3 Aufl.) From mud from canals. Forms hydrogen and CO_2 from anaerobic cellulose fermentations.

Bacillus funicularis Gerstner. (Thesis, Basel, 1894, 24.) From soil and sewage.

Bacillus gangraenae Tilanus. (Nederl. Tijdschr. v. Geneeskunde, *21*, 1885, 110.) From a gangrenous human leg.

Bacillus gracilis ethylicus Achalme and Rosenthal. (Compt. rend. Soc. Biol., Paris, *58*, 1906. 1025.) From stomach contents in a case of gastritis.

Bacillus granulosus Gerstner. (Gerstner, Thesis, Basel, 1894, 21; *Bacillus granulatus* Migula, Syst. d. Bakt., *2*, 1900, 613.) From soil and sewage.

Bacillus haumani Soriano. (Unnamed plectridium, Sordelli and Soriano, Compt. rend. Soc. Biol., Paris, *99*, 1928, 1517; Plectridio amarillo, Soriano, Tomo commemorativo del XXV aniversario de la fundación de la Facultad de Agronomia y Veterinaria, Buenos Aires, 1929, (?); Soriano, Rev. Inst. Bact., Buenos Aires, *5*, 1930, 743; *Plectridium amarillum* Stampa, Ann. Brass. et Distill., *29*, 1930–31, (253, 271 and 302?); *Bacillus haumanni* Arnaudi, Boll. Ist. Sieroter., Milano, *16*, 1937, 650; *Clostridium haumanni* Prévot, Ann. Inst. Past., *61*, 1938, 81.) From flax-retting beds.

Bacillus ichthyismi Konstansoff. (Vestnik Obshtch. Hig. Sudeb. i Prakt. Med., Petrograd, *51*, 1915, (766?); quoted from Weinberg et al., Les Microbes Anaérobies, 1937, 341.) From fish responsible for a condition simulating botulism.

Bacillus indolicus Gratz and Vas. (Gratz and Vas, Cent. f. Bakt., II Abt., *41*, 1914, 511; *Inflabilis indolicus* Prévot, Ann. Inst. Past., *61*, 1938, 77.) From cheese.

Bacillus infantilism Hill and Whitcomb. (Amer. Jour. Pub. Health, *3*, 1913, 926.) From human intestine.

Bacillus inflatus Koch. (Koch, Botan. Zeit., *46*, 1888, 328; *Clostridium inflatum* Trevisan, I generi e le specie delle Batteriacee, 1889, 22; not *Bacillus inflatus* Distaso, Ann. Inst. Past., *23*, 1909, 955.) Anaerobic status insecure; aerobic according to Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 259. Observed in swamp waters, but not isolated. Formed two spores in a spindle-shaped sporangium.

Bacillus irregularis Choukévitch. (Choukévitch, Ann. Inst. Past., *25*, 1911, 348; *Clostridium irregularis* Prévot, Ann. Inst. Past., *61*, 1938, 85.) From large intestine of horse.

Bacillus kedrowskii Migula. (*Bacillus* No. 2, Kedrowski, Ztschr. f. Hyg., *16*, 1894, 451; *Bacillus acidi butyrici* Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 256; not *Bacillus acidi butyrici I* Weigmann, Cent. f. Bakt., II Abt., *4*, 1898, 830 (see *Bacillus pseudonavicula*); Migula, Syst. d. Bakt., *2*, 1900, 589.) From cheese and rancid butter.

Bacillus lactopropylbutyricus Tissier. (Apparently identical with *Bacillus lactopropylbutyricus non liquefaciens* Tissier and Gasching, Ann. Inst. Past., *17*, 1903, 546; Tissier, Ann. Inst. Past., *19*, 1905, 282; *Clostridium lactopropylbutylicum* Prévot, Ann. Inst. Past., *61*, 1938, 85; *Bacillus lactopropylbutylicus non*

liquefaciens Prévot, Man. d. Class., etc., 1940, 141.) From milk.

Bacillus lichenoides Piening. (Cent. f. Bakt., I Abt., Orig., *124*, 1932, 217; not *Bacillus lichenoides* Grohmann, Cent. f. Bakt., II Abt., *61*, 1924, 267.) Cited only by name, without description. From dried sheep intestines used for preparation of catgut sutures.

Bacillus limosus Klein. (Ber. d. Deutsch. Bot. Gesellsch., *7* (Bhft.), 1889, 60.) Migula (Syst. d. Bakt., *2*, 1900, 640) says this is probably anaerobic. Observed in swamp water, but not cultivated on artificial media.

Bacillus longus Chester. (*Bacillus muscoides colorabilis* Ucke, Cent. f. Bakt., I Abt., *23*, 1898, 1000; Chester, Man. Determ. Bact., 1901, 303.) From garden soil.

Bacillus lubinskii Kruse. (Tetanusähnlicher Bacillus, Lubinski, Cent. f. Bakt., *16*, 1894, 771; Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 267.) From a fetid human abdominal abscess in peritonitis.

Bacillus lyticus Costa and Troisier. (Compt. rend. Soc. Biol., Paris, *78*, 1915, 433.) From gangrenous war wounds. Stated to be intermediate between *Clostridium perfringens* and *Clostridium septicum*.

Bacillus macrosporus Klein. (Ber. d. Deutsch. Bot. Gesellsch., *7* (Bhft.), 1889, 60.) Migula (Syst. d. Bakt., *2*, 1900, 640) says this is probably anaerobic. Observed in swamp water, but not cultivated on artificial media.

Bacillus makrono-filiformis Becker. (Ztschr. f. Infkrnkh. d. Haust., *23*, 1922, 20.) From a guinea pig cadaver.

Bacillus maymonei Carbone. (Boll. Sez. Ital., Soc. Intern. Microbiol., *1*, 1929, 74.) A retting organism of doubtful purity and anaerobic status. Cultivated from kenaf (*Hibiscus cannabinus*).

Bacillus megalosporus Choukévitch. (Choukévitch, Ann. Inst. Past., *25*, 1911, 351; *Hiberillus megalosporus* Heller, Jour. Bact., *7*, 1922, 17; *Inflabilis megalosporus* Prévot, Ann. Inst. Past., *61*, 1938, 77.) From large intestine of horse.

Bacillus multiformis Distaso. (Distaso, Cent. f. Bakt., I Abt., Orig., *59*, 1911, 101; not *Bacillus multiformis* van Senus, Dissert., Leiden, 1890, (?); *Bacteroides multiformis* Bergey, Manual, 1st ed., 1923, 263; *Cillobacterium multiforme* Prévot, Ann. Inst. Past., *60*, 1938, 297.) Stated by Distaso (*loc. cit.*) not to produce spores, but to belong probably to the Welch Group. From feces of dog.

Bacillus multiformis van Senus. (van Senus, Dissert., Leiden, 1890 and Koch's Jahrsber., *1*, 1890, 138.) From mud and from decomposing vegetation.

Bacillus muscoides Liborius. (Liborius, Ztschr. f. Hyg., *1*, 1886, 163; *Cornilia muscoides* Trevisan, I generi e le specie delle Batteriacee, 1889, 22.) From mouse inoculated with soil, from cheese, and from bovine feces.

Bacillus muscoides non colorabilis Ucke. (Cent. f. Bakt., I Abt., *23*, 1898, 1000.) From hay infusion.

Bacillus nanus Romanovitch. (Compt. rend. Soc. Biol., Paris, *71*, 1911, 239.) From human intestine.

Bacillus nebulosus Vincent. (Ann. Inst. Past., *21*, 1907, 69; not *Bacillus nebulosus* Wright, Mem. Nat. Acad. Sci., 7, 1894, 465; not *Bacillus nebulosus* Hallé, Thèse de Paris, 1898, 33; not *Bacillus nebulosus* Migula, Syst. d. Bakt., *2*, 1900, 844; not *Bacillus nebulosus* Goresline, Jour. Bact., *27*, 1934, 52.) From well and river water.

Bacillus oedematis Migula. (*Bacillus oedematis maligni* Liborius, Ztschr. f. Hyg., *1*, 1886, 158; not *Bacillus oedematis maligni* Zopf, Die Spaltpilze, 3 Aufl., 1885, 88; Migula, Syst. d. Bakt., *2*, 1900, 604; not *Bacillus oedematis* Chester, Man. Determ. Bact., 1901, 292.)

Bacillus otitidis sporogenes putrificus von Hibler. (Cent. f. Bakt., I Abt., Orig., *68*, 1913, 282.) From a human brain abscess.

Bacillus otricolare Weinberg and Ginsbourg. (Bacillo otricolare, Nacciarone, Riforma Med., *33*, 1917, 778; Weinberg

and Ginsbourg, Bull. Inst. Past., *23*, 1925, 825; *Endosporus otricolare* Prévot, Ann. Inst. Past., *61*, 1938, 75.) From human gaseous gangrene.

Bacillus pappulus de Gasperi. (de Gasperi, Cent. f. Bakt., I Abt., Orig., *58*, 1911, 1; *Paraplectrum pappulum* Prévot, Ann. Inst. Past., *61*, 1938, 75.) From rancid sausages.

Bacillus parabutyricus Gratz and Vas. (Gratz and Vas, Cent. f. Bakt., II Abt., *41*, 1914, 510; not *Bacillus parabutyricus* LeBlaye and Guggenheim, Man. Prat. de Diag. Bact., 1914, 324.) From Liptauer cheese.

Bacillus penicillatus Gerstner. (Inaug. Diss., Basel, 1894, 27.) From soil and sewage.

Bacillus peroniella Klein. (Ber. d. Deutsch. Bot. Gesellsch., *7* (Bhft.), 1889, 60.) Migula (Syst. d. Bakt., *2*, 1900, 640) says this is probably anaerobic. Observed in swamp water, but not cultivated on artificial media.

Bacillus polypiformis Liborius. (Liborius, Ztschr. f. Hyg., *1*, 1886, 162; *Cornilia polypiformie* Trevisan, I generi e le specie delle Batteriacee, 1889, 22; Anaerobe No. II, Sanfelice, Ztschr. f. Hyg., *14*, 1893, 369; *Bacillus cephaloideus* Migula, Syst. d. Bakt., *2*, 1900, 631.) From mouse inoculated with soil.

Bacillus postumus Heim. (Heim, Lehrbuch d. Bakt., 3 Aufl., 1906, (?) (p. 259 in 6 Aufl.); quoted from Würcker, Sitzungsber. d. Physik.-Med. Soz. in Erlangen, *41*, 1909, 230; also Heim, Cent. f. Bakt., I Abt., Orig., *55*, 1910, 341.) From various spontaneously putrefying infusions.

Bacillus pseudomagnus Migula. (Anaerobe No. VI, Sanfelice, Ztschr. f. Hyg., *14*, 1893, 373; Migula, Syst. d. Bakt., *2*, 1900, 608; *Bacillus caris* Chester, Man. Determ. Bact., 1901, 293.) From putrefying meat infusions, soil and animal excreta.

Bacillus pseudonavicula Migula. (Species No. 1, Kedrowski, Ztschr. f. Hyg., *16*, 1894, 445; *Bacillus acidi butyrici I* Weigmann, Cent. f. Bakt., II Abt., *4*, 1898, 830; not *Bacillus acidi butyrici* Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 256; Migula, Syst. d. Bakt., *2*, 1900, 590.) From cheese and rancid butter.

Bacillus pseudooedematis Kruse. (Pseudo - Oedembacillen, Liborius, Ztschr. f. Hyg., *1*, 1886, 163; *Bacillus pseudo-oedematis maligni* Gerstner, Inaug. Diss., Basel, 1894, 35; not *Bacillus pseudooedematis maligni* Sanfelice, Ann. dell'Ist. d'Ig. di Roma, n.s. *1*, 1891, 370; Anaerobe No. VII, Sanfelice, Ztschr. f. Hyg., *14*, 1893, 374; Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 239; *Bacillus pseudoedematis* Chester, Man. Determ. Bact., 1901, 293; presumably identical with *Bacillus pseudo-septicus* Perrone, Ann. Inst. Past., *19*, 1905, 371, and, according to Perrone, with *Proteus hominis capsulatus* Bordoni-Uffreduzzi, Ztschr. f. Hyg., *3*, 1888, 333.) From mouse inoculated with soil, from putrefying meat infusions and from animal excreta.

Bacillus pseudosolidus Migula. (Anaerobe No. III, Sanfelice, Ztschr. f. Hyg., *14*, 1893, 371; Migula, Syst. d. Bakt., *2*, 1900, 630; *Bacillus tardus* Chester, Man. Determ. Bact., 1901, 294; not *Bacillus tardus* Choukévitch, Ann. Inst. Past., *25*, 1911, 350.) From putrefying meat infusions, soil, and from animal excreta.

Bacillus pseudotetani Migula. (Pseudotetanusbacillus, Tavel and Lanz, Mitt. a. klin. med. Inst. d. Schweiz, *1*, 1893, 162; Migula, Syst. d. Bakt., *2*, 1900, 598; *Bacillus taveli* Chester, Man. Determ. Bact., 1901, 304.) From cases of intestinal abscesses.

Bacillus pseudotetanicus Kruse. (Anaerobe IX, Sanfelice, Ztschr. f. Hyg., *14*, 1893, 375; Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 267; not *Bacillus pseudotetanicus* Migula, Syst. d. Bakt., *2*, 1900, 626; not *Bacillus pseudotetanicus* Chester, Man. Determ. Bact., 1901, 302; *Bacillus subtetanicus* Migula, *loc. cit.*, 629.) From putrefying meat infusions and from soil.

Bacillus putrificus coagulans Distaso. (Cent. f. Bakt., I Abt., Orig., *59*, 1911, 97.) From human and animal intestine.

Bacillus putrificus var. *non liquefaciens* Putzu. (Policlin., Sez. Chir., *23*, 1916, 225.) From human gas gangrene.

Bacillus putrificans immobilis Distaso. (Ann. Inst. Past., *23*, 1909, 962.) From the feces of the flying fox (*Pteropus*).

Bacillus pyogenes foetidus Herfeldt. (Cent. f. Bakt., II Abt., *1*, 1895, 77.) From manure and from horse intestine.

Bacillus reniformis Gerstner. (Gerstner, Inaug. Diss., Basel, 1894, 22; *Bacterium reniforme* Migula, Syst. d. Bakt., *2*, 1900, 329.) From soil and sewage.

Bacillus rubellus Okada. (Okada, Cent. f. Bakt., *11*, 1892, 4; *Clostridium rubellum* Prévot, Ann. Inst. Past., *61*, 1938, 85.) From dust and dirt.

Bacillus saccharofermentans de Gasperi. (Compt. rend. Soc. Biol., Paris, *67*, 1909, 494.) From putrefying carcasses of game birds.

Bacillus saccharogenes Romanovitch. (Compt. rend. Soc. Biol., Paris, *71*, 1911, 168.) From human intestine, both normal and during appendicitis.

Bacillus saprogenes I, II and *III*, Herfeldt. (Herfeldt, Cent. f. Bakt., II Abt., *1*, 1895, 77; not *Bacillus saprogenes* Salus, Arch. f. Hyg., *51*, 1904, 115.) From manure and from horse intestine.

Bacillus saprogenes intestinalis Romanovitch. (Compt. rend. Soc. Biol., Paris, *71*, 1911, 237.) From human intestine.

Bacillus saprophyticus Maes. (Surg. Clin. North Amer., *10*, 1930, 792.) Only casual mention of this organism as one of the common gas bacilli. Otherwise unidentified.

Bacillus saprotoxicus Sordelli, Soriano, Ferrari and Torino. (Sordelli et al., Rev. d. Inst. Bact., Buenos Aires, *6*, 1934, 432; *Clostridium saprotoxicum* Prévot, Ann. Inst. Past., *61*, 1938, 83.) From human gaseous gangrene.

Bacillus sarcoemphysematodes hominis Conradi and Bieling. (Münch. med. Wchnschr., *63*, 1916, 133.) From human lesions.

Bacillus satellitis Loris-Melikov. (Unnamed species of Loris-Melikov, Compt. rend. Soc. Biol., Paris, *70*, 1911, 865; Loris-Melikov, Ann. Inst. Past., *27*, 1913, 545; *Bacillus satelitis* (sic) Loris-Melikov, Compt. rend. Acad. Sci., Paris, *156*, 1913, 346; *Inflabilis satellitis* Prévot, Ann. Inst. Past., *61*, 1938, 77.) From human typhoid feces.

Bacillus scatologenes Weinberg and Ginsbourg. (Skatol-liberating *Clostridium*, Fellers, Abst. Bact., *7*, 1923, 351; Bacillus skatol, Fellers and Clough, Jour. Bact., *10*, 1925, 105; Weinberg and Ginsbourg, Les Microbes Anaérobies, Paris, 1927, 54.) From spoiled canned macaroni and salmon.

Bacillus septicus Klein. (Klein, Micro-Organisms and Disease, London, 1884, 78; not *Bacillus septicus* Macé, Traité Prat. d. Bact., 1st ed., 1888, 455; not *Bacillus septicus* Migula, Syst. d. Bakt., *2*, 1900, 646.) Probably synonymous with *Clostridium perfringens* Type A. From earth, putrid blood and other albuminous fluids, and occasionally in blood-vessels of man and animals after death.

Bacillus solidus Lüderitz. (Lüderitz, Ztschr. f. Hyg., *5*, 1889, 152; not *Bacillus solidus* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *10*, 1898, 129; *Cornilia solida* Trevisan, I generi e le specie delle Batteriacee, 1889, 22.) From mouse and guinea pig inoculated with soil.

Bacillus solmsii Klein. (Klein, Ber. d. Deutsch. Bot. Gesellsch., *7* (Bhft.), 1889, 60; *Diplectridium solmsii* Fischer, Jahrb. f. Wiss. Bot., *27*, 1895, 148). Migula (Syst. d. Bakt., *2*, 1900, 640) says this is probably anaerobic. Observed in swamp water, but not cultivated on artificial media.

Bacillus spinosus Lüderitz. (Lüderitz, Ztschr. f. Hyg., *5*, 1889, 152; *Cornilia spinosa* Trevisan, I generi e le specie delle Batteriacee, 1889, 22.) From mouse and guinea pig inoculated with soil.

Bacillus sporogenes Migula. (*Bacillus enteritidis sporogenes* Klein, Cent. f. Bakt., I Abt., *18*, 1895, 737; Migula, Syst. d. Bakt., *2*, 1900, 560; *Bacillus (enteritidis) sporogenes* and *Bacillus enteritidis* Klein, Loc. Govt. Bd., Ann. Rept. Med. Off., London, *33*, 1903-04, 442 and 443; *Bacillus sporogenes capsulatus* Rettger, Jour. Biol. Chem., *2*, 1906-07, 84; *Bacillus enteritidis-sporogenes* Holland, Jour. Bact., *5*, 1920, 218; *Clostridium enteritidis-sporogenes* Holland, *ibid.*, 218; *Clostridium enteritidis sporogenes* Holland, *ibid.*, 222; *Clostridium sporogenes* Holland, *ibid.*, 220.) Probably a culture of *Clostridium perfringens* contaminated with *Clostridium bifermentans* or with *Clostridium sporogenes*. From epidemic diarrheal feces, and from milk presumably causing the epidemic.

Bacillus sporogenes non liquefaciens Jungano. (Jungano, Compt. rend. Soc. Biol., Paris, *65*, 1908–09, 716; *Bacillus sporogenes liquefaciens* Jungano, *ibid.*, 718; *Bacillus sporogenes non liquefaciens anaerobius* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., 1914, 395.) From the intestine of the flying fox (*Pteropus*).

Bacillus sporogenes foetidus Choukévitch. (Ann. Inst. Past., *25*, 1911, 257.) From the large intestine of a horse.

Bacillus sporogenes parvus Choukévitch. (Ann. Inst. Past., *27*, 1913, 251.) From intestine of cattle.

Bacillus stellatus Vincent. (Vincent, Ann. Inst. Past., *21*, 1907, 69; *Bacillus stellatus anaerobius* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., 1914, 368; *Bacterium stellatum* LeBlaye and Guggenheim, *idem.*) Anaerobic status uncertain, but Vincent compares it with *Bacillus polypiformis* Liborius, and with Anaerobe No. II, Sanfelice. From water.

Bacillus subfoetidus Migula. (Anaerobe V, Sanfelice, Ztschr. f. Hyg., *14*, 1893, 372; Migula, Syst. d. Bakt., *2*, 1900, 609; *Bacillus anaerobic No. V* Chester, Man. Determ. Bact., 1901, 296; *Bacillus pseudotetanicus* Chester, *ibid.*, 302.) From putrefying meat infusions, soil, and from animal excreta.

Bacillus tachysporus Wesbrook. (Jour. Path. and Bact., *4*, 1896–97, 8.) From infection in human tetanus.

Bacillus tenuis glycolyticus Distaso. (Ann. Inst. Past., *23*, 1909, 955.) From intestine of the flying fox (*Pteropus*).

Bacillus tenuis spatuliformis Distaso. (Distaso, Cent. f. Bakt., I Abt., Orig., *59*, 1911, 101; *Bacteroides tenuis* Bergey et al., Manual, 1st ed., 1923, 263; *Cillobacterium spatuliforme* Prévot, Ann. Inst. Past., *60*, 1938, 297; *Bacillus spatuliformis* Prévot, Man. d. Class., etc., 1940, 79.) Spores not observed by Distaso, but placed by him in the perfringens-group. From feces of dog.

Bacillus teras Knorr. (Knorr, Cent. f. Bakt., I Abt., Orig., *82*, 1918–19, 225; *Inflabilis teras* Prévot, Ann. Inst. Past., *61*, 1938, 77.) From soil and from fluid aspirated in hematopneumothorax.

Bacillus thalassophilus Russell. (Russell, Ztschr. f. Hyg., *11*, 1892, 189.) Variably recorded as a strict or facultative anaerobe (see *Bacillus polymyxa* and *Bacillus sphaericus*). From sea water and mud from depth of sea.

Bacillus thermofibrincolus Itano and Arakawa. (Bull. Agric. Chem. Soc., Japan, *5*, 1929, 33.) Source not recorded.

Bacillus tympani-cuniculi Morcos. (Jour. Bact., *23*, 1932, 454.) From viscera, muscles and blood of rabbits dying of infectious tympanitis.

Bacillus ukilii Weinberg, Prévot, Davesne and Renard. (Unnamed species of Ukil, Compt. rend. Soc. Biol., Paris, *87*, 1922, 1009; Weinberg et al., Ann. Inst. Past., *42*, 1928, 1199; *Bacillus oedematogenes* Frei, Ergeb. d. allgem. Path. Mensch. u. Tiere, *31*, 1936, 52; *Clostridium ukilii* Hauduroy et al., Dict. d. Bact. Path., 1937, 142; *Clostridium oedematis-benigni* Prévot, Ann. Inst. Past., *61*, 1938, 82; *Clostridium oedematis benigni* Prévot, Man. d. Class., etc., 1940, 120.) From diseased human appendix.

Bacillus ventriculosus Koch. (Koch, Botan. Zeit., *46*, 1888, 341; *Clostridium ventriculosus* Trevisan, I generi e le specie delle Batteriacee, 1889, 22.) Prob-

ably not anaerobic. Observed in decaying vegetation and in swampy waters.

Bacterium coprophilum Migula. (Anaerobe No. 2, Sewerin, Cent. f. Bakt., II Abt., *3*, 1897, 708; Migula, Syst. d. Bakt., *2*, 1900, 323; *Bacillus coprophilus* Weinberg, Nativelle and Prévot, Les Microbes Anaér., 1937, 643.) From horse manure.

Bacterium lini Migula. (Unnamed species of Winogradsky, Compt. rend. Acad. Sci., Paris, *121*, 1895, 744; Migula, Syst. d. Bakt., *2*, 1900, 513. From retting flax.

Bacterium pseudoclostridium Migula. (*Clostridium foetidum lactis* von Freudenreich, Cent. f. Bakt., II Abt., *1*, 1895, 856; Migula, Syst. d. Bakt., *2*, 1900, 511.) From cheese.

Bacterium sternbergii Migula. (*Bacillus anaerobicus liquefaciens* Sternberg, Researches relating to the etiology and prevention of yellow fever, Washington, 1891, 214; *Bacillus anaerobius liquefaciens* Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 241; Migula, Syst. d. Bakt., *2*, 1900, 444; *Bacterium anaerobicum* Chester, Man. Determ. Bact., 1901, 198.) From intestine of a yellow fever cadaver.

Bactridium butyricum Chudiakow. (Chudiakow, Zur Lehre von der Anaerobiose, Teil I, Moskau, 1896, (?); quoted from Rothert, Cent. f. Bakt., II Abt., *4*, 1898, 390.) Stated by Rothert to be a pathogenic, obligate anaerobe, but source of culture is not specified.

Caduceus thermophilus α Prévot. (Anaerobie thermophile α (Thermo α), Veillon, Ann. Inst. Past., *36*, 1922, 428; Prévot, Ann. Inst. Past., *61*, 1938, 86; *Bacillus thermophilus* α Prévot, Man. d. Class., etc., 1940, 150; *Caduceus thermophilus* Prévot, *ibid.*, 149; *Caduceus thermophilus alfa* Prévot, *ibid.*, 150.) From horse manure.

Clostridium aceticum Wieringa. (Jour. Microbiol. and Serol., *6*, 1940, 257.) From soil. Oxidizes H_2, using CO_2 as the hydrogen acceptor, forming acetic acid, thus using H_2 as sole source of growth energy and CO_2 as sole carbon source for cell growth.

Clostridium albo-lacteum Killian and Fehér. (Ann. Inst. Past., *55*, 1935, 620.) From Sahara Desert soil.

Clostridium alboluteum Killian and Fehér. (Ann. Inst. Past., *55*, 1935, 595.) From Sahara Desert soil.

Clostridium album liquefaciens Killian and Fehér. (Ann. Inst. Past., *55*, 1935, 595.) From Sahara Desert soil.

Clostridium album minor Killian and Fehér. (Ann. Inst. Past., *55*, 1935, 620.) Presumably identical with *Clostridium minor* Killian and Fehér, *ibid.*, 597. From Sahara Desert soil.

Clostridium album non liquefaciens Killian and Fehér. (Ann. Inst. Past., *55*, 1935, 599.) Presumably identical with *Clostridium non liquefaciens* Killian and Fehér, *ibid.*, 597. From Sahara Desert soil.

Clostridium americanum Pringsheim. (Eine Alkohole bildende Bakterienform, Pringsheim, Cent. f. Bakt., II Abt., *15*, 1906, 300; *Bacillus pringsheim* Pringsheim, *ibid.*, 311; Pringsheim, Cent. f. Bakt., II Abt., *16*, 1906, 796; *Clostridium butyricum* var. *americanum* Prévot, Man. d. Class., etc., 1940, 109.) Anaerobic status uncertain. From spontaneously fermenting potato.

Clostridium aurantibutyricum Hellinger. (Commemorative Vol. to Dr. Ch. Weizmann's 70th Birthday, Nov., 1944, 46.) From retted *Hibiscus* from So. Africa.

Clostridium balaenae Prévot. (Walfischseptikämie Bacillus, Nielsen, Cent. f. Bakt., *7*, 1890, 269; Bacille de la septicémie des baleines, Christiansen, Compt. rend. Soc. Biol., Paris, *83*, 1920, 324; Walfischseptikämiebazillus, Christiansen, Cent. f. Bakt., I Abt., Orig., *84*, 1920, 127; Prévot, Ann. Inst. Past., *61*, 1938, 81.) From flesh of whales dying of septicemia. Later isolated from same material by Christiansen.

Clostridium canadiense Dernby and Blanc. (Jour. Bact., *6*, 1921, 420.) From a human case of gangrene.

Clostridium caproicum Prévot. (*Ba-*

cillus anaerobicus der Capronsäuregruppe, Rodella, Cent. f. Bakt., II Abt., *16*, 1906, 58; Prévot, Ann. Inst. Past., *61*, 1938, 84; *Bacillus anaerobicus caproicus* Prévot, Man. d. Class., etc., 1940, 140.) From cheese.

Clostridium cellobioparus Hungate. (Jour. Bact., *48*, 1944, 499.) From rumen of cattle.

Clostridium cellulosae Horowitz-Wlassowa and Novotelnow. (Cent. f. Bakt., II Abt., *91*, 1935, 477.) Cited only by name. Source not stated.

Clostridium corallinum Prévot and Raynaud. (Ann. Inst. Past., *70*, 1944, 182.) From serous fluid obtained post mortem from a mouse inoculated with an emulsion of street dust.

Clostridium cuniculi Galli. (Galli, Boll. Ist. Sieroter., Milan, *3*, 1923–24, 337; *Clostridium gallii* Prévot, Ann. Inst. Past., *61*, 1938, 83.) From necrotic visceral lesion in a rabbit.

Clostridium disporum Vuillemin. (Compt. rend. Acad. Sci., Paris, *136*, 1903, 1583.) Probably not anaerobic. Encountered in cultures of *Blastomyces;* said to form two spores.

Clostridium foetidum fecale Romanovitch. (Compt. rend. Soc. Biol., Paris, *71*, 1911, 238.) From normal human intestine.

Clostridium ghoni Prévot. (Unnamed species of Ghon and Mucha, Cent. f. Bakt., I Abt., Orig., *39*, 1905, 497; Prévot, Ann. Inst. Past., *61*, 1938, 83.) From post-operative human peritonitis.

Clostridium giganteum Benecke and Keutner. (Ber. d. Deutsch. Botan. Gesellsch., *21*, 1903, 340.) From sea water.

Clostridium haemolysans Hauduroy et al. (*Bacillus anaerobius haemolysans* Markoff, Cent. f. Bakt., I Abt., Orig., *77*, 1915–16, 421; Hauduroy et al., Dict. d. Bact. Path., 1937, 105; *Plectridium hemolysans* Prévot, Ann. Inst. Past., *61*, 1938, 87.) From putrid human buccal tissues.

Clostridium hueppei Trevisan. (Buttersäurebacillen, Hueppe, Mitteil. a. d. kais. Gesundhts., *2*, 1884, 353; *Bacillus butyricus* Flügge, Die Mikroorg., 2 Aufl., 1886, 300; Trevisan, I generi e le specie delle Batteriacee, 1889, 22; *Bacillus pseudo-butyricus* Kruse, in Flügge, Die Mikroorg., 3 Aufl., *2*, 1896, 207; *Bacillus hueppei* Chester, Man. Determ. Bact., 1901, 276.) From milk.

Clostridium hyalinum Killian and Fehér. (Ann. Inst. Past., *55*, 1935, 595.) From Sahara Desert soil.

Clostridium kluyverii Barker and Taha. (Jour. Bact., *43*, 1942, 347.) From alcohol-containing enrichment cultures of *Methanobacterium omelianskii* inoculated with black mud from fresh water and marine sources.

Clostridium liborii Trevisan. (Liborius buttersäurebildender Bacillus, Flügge, Die Mikroorg., 2 Aufl., 1886, 299; Trevisan, I generi e le specie delle Batteriacee, 1889, 22.) Presumably the same as *Clostridium foetidum* Liborius, Ztschr. f. Hyg., *1*, 1886, 160. From mice inoculated with garden soil.

Clostridium medium Henneberg. (Cent. f. Bakt., II Abt., *55*, 1922, 248.) From human and animal feces.

Clostridium mitelmani Prévot. (Ann. Inst. Past., *61*, 1938, 84.) Stated by Prévot to have been isolated by Mitelman from diarrheal human intestine.

Clostridium mucosus Simola. (Simola, Ann. Acad. Scient. Fennicoe, Helsinki, Ser. A, *34*, 1931, (115?); *Clostridium mucosum* Prévot, Man. d. Class., etc., 1940, 112; not *Clostridium mucosum* Bergey et al., Manual, 4th ed., 1934, 472; quoted from Prévot, Ann. Inst. Past., *61*, 1938, 80 who records it as a facultative anaerobe.) Source of isolation unknown.

Clostridium myxogenes Simola. (Simola, Ann. Acad. Scient. Fennicoe, Helsinki, Ser. A, *34*, 1931, (115?); quoted from Prévot, Ann. Inst. Past., *61*, 1938, 80 who records it as a facultative anaerobe.) Source of isolation unknown.

Clostridium necrosans Prévot. (*Bacillus aerogenes necrosans* Schupfer, Policlin., Sez. Med., *12*, 1905, 261; Prévot, Ann. Inst. Past., *61*, 1938, 84.) Isolated

from a gaseous, necrotic thoracic abscess in a woman.

Clostridium nothnageli Henneberg. (Cent. f. Bakt., II Abt., *55*, 1921–22, 245.) Cultivated, but not isolated in pure culture, from human and animal feces.

Clostridium partum Prévot. (Unnamed anaerobe of Levens, Cent. f. Bakt., I Abt. Orig., *88*, 1922, 479; Prévot, Ann. Inst. Past., *61*, 1938, 85.) From a cow in post-partum rausch-brand.

Clostridium propionicum Cardon and Barker. (Jour. Bact., *52*, 1946, 629.) From marine mud.

Clostridium proteolyticum Choukévitch. (Ann. Inst. Past., *27*, 1913, 253.) Said to be a facultative anaerobe. From intestine of cattle.

Clostridium pygmaeum Henneberg. (Cent. f. Bakt., II Abt., *55*, 1921–22, 250.) From human and animal feces.

Clostridium sarcoemphysematodes Prévot. (*Bacillus sarcemphysematodes hominis* Conradi and Bieling, Münch. med. Wochnschr., *63*, 1916, 134; *Clostridium sarcemphysematodes* (sic) Prévot, Ann. Inst. Past., *61*, 1938, 81; Prévot, Man. d. Class., etc., 1940, 120.) From human gaseous gangrene.

Clostridium sardiniensis Prévot. (Ann. Inst. Past., *61*, 1938, 81.) Referred to Altara by Prévot. Cited by name only from Prévot.

Clostridium secundum Hauduroy et al. (Unnamed species of Ghon and Sachs, Cent. f. Bakt., I Abt., Orig., *48*, 1909, 399; Hauduroy et al., Dict. d. Bact. Path., 1937, 130.) From human emphysematous liver.

Clostridium solidum Sanfelice. (Sanfelice, Ztschr. f. Hyg., *14*, 1893, 372; *Bacillus solidum* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *10*, 1898, 129; *Bacillus sanfelicei* Migula, Syst. d. Bakt., *2*, 1900, 630; not *Bacillus solidus* Lüderitz, Ztschr. f. Hyg., *5*, 1889, 152.) From putrefying meat infusions, soil and from animal excreta.

Clostridium sphaeroides Killian and Fehér. (Ann. Inst. Past., *55*, 1935, 598.) From Sahara Desert soil.

Clostridium strasburgense Hauduroy et al. (Unnamed species of Vaucher, Boez, Lanzenberg and Kehlstadt, Bull. et Mem. Soc. Méd. Hôp. Paris, *49*, 1925, 1641; Hauduroy et al., Dict. d. Bact. Path., 1937, 135; *Inflabilis sanguicole* Prévot, Ann. Inst. Past., *61*, 1938, 77.) Isolated by blood culture in human puerperal septicemia.

Clostridium tenue Hauduroy et al. (*Bacillus anaerobicus tenuis* Distaso, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 439; *Bacillus anaerobius tenuis* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., 1914, 337; Hauduroy et al., Dict. d. Bact. Path., 1937, 136.) From normal human intestine.

Clostridium thermoacidophilus Damon and Feirer. (Damon and Feirer, Jour. Bact., *10*, 1925, 41; *Palmula thermoacidophila* Prévot, Ann. Inst. Past., *61*, 1938, 89; *Acuformis thermoacidophilus* Prévot, Man. d. Class., etc., 1940, 165.) Isolated anaerobically, but not strictly anaerobic. From horse manure.

Clostridium thermoaerogenes Damon and Feirer. (Damon and Feirer, Jour. Bact., *10*, 1925, 40; *Caduceus thermoaerogenes* Prévot, Ann. Inst. Past., *61*, 1938, 86.) From horse manure.

Clostridium thermocellum Viljoen, Fred and Peterson. (Viljoen et al., Jour. Agric. Sci. (London), *16*, 1926, 7; *Terminosporus thermocellus* Prévot, Ann. Inst. Past., *61*, 1938, 86.) From horse manure.

Clostridium thermochainus Damon and Feirer. (Jour. Bact., *10*, 1925, 42.) From horse manure.

Clostridium thermophilum Jemel'jantschik and Borissowa. (Microbiology (Russian), *10*, 1941, 236–241; *Bacillus thermophilus anaerobicus, idem;* abst. in Cent. f. Bakt., II Abt., *105*, 1942, 148; not *Clostridium thermophilum* Pribram, Jour. Bact., *22*, 1931, 430.) From fish conserves.

Clostridium thermoputrificum Damon and Feirer. (Damon and Feirer, Jour. Bact., *10*, 1925, 39; *Palmula thermopu-*

trifica Prévot, Ann. Inst. Past., *61*, 1938, 89; *Acuformis thermoputrificus* Prévot, Man. d. Class., etc., 1940, 165.) From horse manure.

Clostridium toxinogenes Prévot. (Unnamed anaerobe of Kojima, Ztschr. f. Hyg., *99*, 1923, 86; Prévot, Ann. Inst. Past., *61*, 1938, 82.) From muscle of a cow dying of symptomatic anthrax.

Clostridium ureolyticum Prévot. (Ann. Inst. Past., *61*, 1938, 85; presumably Erde A, Geilinger, Cent. f. Bakt., II Abt., *47*, 1917, 252.) From manured soil.

Clostridium valerianicum Prévot. (Fäulnisanaerobien der Baldriansäure, Rodella, Cent. f. Bakt., II Abt., *16*, 1906, 62; Prévot, Ann. Inst. Past., *61*, 1938, 84.) From cheese.

Clostridium viscosum Chudiakow. (Zur Lehre von der Anaerobiose, Teil I, 1896 (Russ.); quoted from Rothert, Cent. f. Bakt., II Abt., *4*, 1898, 390.) A facultative anaerobe.

Clostridium xanthogenum DeGraaff. (Nederl. Tijd. Hyg., Microbiol. en Serol., *4*, 1930, 219.) From cultured buttermilk undergoing atypical fermentation.

Clostridium zuntzii Henneberg. (Cent. f. Bakt., II Abt., *55*, 1922, 249.) Cultivated, but not isolated in pure culture, from human and animal feces.

Cornilia parva Trevisan. (*Bacillus liquefaciens parvus* Lüderitz, Ztschr. f. Hyg., *5*, 1889, 148; Trevisan, I generi e le specie delle Batteriacee, 1889, 22; *Bacterium parvum* Migula, Syst. d. Bakt., *2*, 1900, 324.) From animals inoculated with garden soil.

Endosporus otricolare Prévot. (Bacillo otricolare, Nacciarone, Riforma Med., Napoli, *33*, 1917, 778; Prévot, Ann. Inst. Past., *61*, 1938, 75.) From gangrenous war wounds.

Granulobacillus sporogenes Andre. (*Granulobacillus sp.*, Sommer, Deutsch. Monatschr. f. Zahnheilk., *33*, 1915, 328; Andre, Ztschr. f. Hyg., *114*, 1933, 412.) From infected, necrotic pulp of human teeth.

Granulobacter lactobutyricum Beijerinck. (Ferment de lactate de chaux, Pasteur, Compt. rend. Acad. Sci., Paris, *56*, 1863, 416; Beijerinck, Verhandl. d. k. Akademie v. Wetensch., Amsterdam, Tweedie Sectie, Deel I, 1893, 8; *Bacillus lactobutyricus* Migula, Syst. d. Bakt., *2*, 1900, 601; *Amylobacter lactobutyricus* van Beynum and Pette, Cent. f. Bakt., II Abt., *93*, 1935, 200.) From fermenting grain mash and from soil.

Granulobacter pectinovorum Beijerinck and van Delden. (*Plectridium pectinovorum* Störmer, Mitteil. d. deutsch. Landwirts. Gesellsch., *18*, 1903, 195; Beijerinck and van Delden, Arch. Néerl. d. Sci. Exactes et Nat., Ser. II, *9*, 1904, 423; *Bacillus pectinovorus* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., 1914, 324; *Bacillus pectinovorum* Henneberg, Cent. f. Bakt., II Abt., *55*, 1922, 279; *Clostridium pectinovorum* Donker, Thesis, Delft, 1926, 145.) From retting plant tissues.

Granulobacter reptans Beijerinck and van Delden. (Cent. f. Bakt., II Abt., *9*, 1902, 13.) Probably aerobic or microaerophilic. From garden and other soils.

Granulobacter sphaericum Beijerinck. (Cent. f. Bakt., II Abt., *7*, 1901, 568.) Probably aerobic or microaerophilic. From garden and other soils.

Granulobacter urocephalum Beijerinck and van Delden. (Arch. Néerl. d. Sci. Exactes et Nat., Ser. II, *9*, 1904, 423.) From retting plant tissues.

Hiblerillus rectus Heller. (*Streptobacillus anaerobicus rectus* Choukévitch, Ann. Inst. Past., *25*, 1911, 350; *Bacillus anaerobius rectus* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., 1914, 337; Heller, Jour. Bact., *7*, 1922, 17; *Inflabilis rectus* Prévot, Ann. Inst. Past., *61*, 1938, 77.) From large intestine of the horse.

Hiblerillus septimus Heller. (Art VII, von Hibler, Untersuch. ü. d. Path. Anaer., 1908, 3 and 406; Heller, Jour. Bact., *7*, 1922, 17; *Clostridium septimum* Prévot, Ann. Inst. Past., *61*, 1938, 84.) From spleen of a guinea pig inoculated with soil.

Inflabilis barati Prévot. (Bacille de Barat, Tissier, Compt. rend. Soc. Biol., Paris, *81*, 1918, 426; Prévot, Ann. Inst. Past., *61*, 1938, 77.) From beer wort.

Inflabilis magnus Prévot. (*Streptobacillus anaerobicus magnus* Choukévitch, Ann. Inst. Past., *25*, 1911, 251; *Bacillus anaerobius magnus* LeBlaye and Guggenheim, Man. Prat. d. Diag. Bact., 1914, 337; Prévot, Ann. Inst. Past., *61*, 1938, 77.) From large intestine of the horse.

Inflabilis plagarum Prévot. (Bacillus S, Adamson, Jour. Path. and Bact., *22*, 1918–19, 373; Prévot, Ann. Inst. Past., *61*, 1938, 77.) From war wounds.

Inflabilis pseudo-perfringens Prévot. (Presumably Bacillus L, Adamson, Jour. Path. and Bact., *22*, 1918–19, 372; Prévot, Ann. Inst. Past., *61*, 1938, 77.) From war wounds.

Inflabilis setiensis Prévot and Raynaud. (Ann. Inst. Past., *70*, 1944, 50.) From oysters.

Martellillus proteolyticus Heller. (Organism II, Hempl, Jour. Hyg., *17*, 1918, 16; Heller, Jour. Bact., *7*, 1922, 26.) From muscle in human gaseous gangrene.

Myerillus sadowa Heller. (Jour. Bact., *7*, 1922, 7; also Barney and Heller, Arch. Surg., *4*, 1922, 477.) From a gangrenous human arm.

Pectinobacter amylophilum Makronov. (Arch. Sci. Biol. (Russ.), *18*, 1915, 441.) Stated by author to be anaerobic, but description does not make this evident. From soil.

Plectridium cellulolyticum Pochon. (Compt. rend. Soc. Biol., Paris, *113*, 1933, 1325.) Isolated anaerobically, but not strictly anaerobic. From stomach of ruminants.

Plectridium pectinovorum liquefaciens Sjolander and McCoy. (Cent. f. Bakt., II Abt., *97*, 1937, 315 and 322; probably identical with *Amylobacter liquefaciens* Ruschmann and Bavendamm, Cent. f. Bakt., II Abt., *64*, 1937, 359.) From spontaneously retting plant tissues.

Plectridium snieszkoi Prévot. (Unnamed anaerobic thermophilic cellulose-fermenting species, Snieszko, Cent. f. Bakt., II Abt., *88*, 1933, 403; Prévot, Man. d. Class., etc., 1940, 154.) From soil and manure.

Recordillus fragilis Heller. (Jour. Bact., *7*, 1922, 8 and 27.) From a liver infarct in a cow.

Reglillus progrediens Heller. (Jour. Bact., *7*, 1922, 7; also Barney and Heller, Arch. Surg., *4*, 1922, 477.) From muscle of a gangrenous human arm.

Robertsonillus primus Heller. (Organism I, Hempl, Jour. Hyg., *17*, 1918, 13; Heller, Jour. Bact., *7*, 1922, 7.) From a gangrenous war wound of human maxilla.

Streptobacillus terrae Ucke. (Cent. f. Bakt., I Abt., *23*, 1898, 1000.) From garden soil.

Terminosporus raabi Prévot. (Unnamed anaerobe of Raab, Jour. Amer. Water Works Assoc., *10*, 1923, 1051; Prévot, Ann. Inst. Past., *61*, 1938, 86). From Minneapolis city water.

Terminosporus thermocellulolyticus Pochon. (Ann. Inst. Past., *68*, 1942, 354, 383 and 467.) Strict anaerobe. Optimum growth at 60° to 66°C.

Tyrothrix catenula Duclaux. (Duclaux, Ann. Inst. Nat. Agron., *4*, 1882, 23; *Cornilia catenula* Trevisan, I generi e le specie delle Batteriacee, 1889, 22; *Bacillus catenula* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *10*, 1898, 123.) Commonly regarded as anaerobic, but not by Migula (Syst. d. Bakt., *2*, 1900, 588). From cheese.

Tyrothrix claviformis Duclaux. (Duclaux, Ann. Inst. Nat. Agron., *4*, 1882, 23; *Pacinia claviformis* Trevisan, *in litt.*, quoted from DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1017; *Bacterium claviforme* Migula, Syst. d. Bakt., *2*, 1900, 322; *Bacillus claviformis* Vincent, Ann. Inst. Past., *21*, 1907, 70.) From cheese.

Tyrothrix urocephalum Duclaux. (Duclaux, Ann. Inst. Nat. Agron., *4*, 1882, 23; *Bacterium urocephalum* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *10*, 1898, 123; *Bacillus urocephalum* Migula, Syst. d. Bakt., *2*, 1900, 588.)

Appendix II. The following organisms are listed in the text as probable synonyms or possibly related species. They are cited here again in order to record the source of the original isolation. For convenience, they are listed alphabetically under the names of the species to which such presumed relationship is ascribed.

1. **Clostridium butyricum** Prazmowski.

Amylobacter non liquefaciens Ruschmann and Bavendamm. From retting plant tissues.

Bacille amylozyme, Perdrix. From city water of Paris, and from the Seine River water.

Bacillus amylobacter S and *W* Wertheim. From soil and tissues of field plants.

Bacillus butylicus Fitz. From glycerol solutions undergoing butylic fermentation after inoculation with fresh cow feces.

Bacillus holobutyricus Perdrix. From putrefying milk.

Bacillus orthobutylicus Grimbert. From soil, grains and from legumes.

Bacillus saccharobutyricus von Klecki. From cheese.

Bacterium navicula Reinke and Berthold. Observed and described from decomposing plant tissues. Not isolated in pure culture.

Bactridium butyricum Chudiakow. Cited by Rothert, and source not stated by abstractor.

Butylbacillus, Buchner. From glycerinated hay infusion.

Clostridium butyricum (*Bacillus amylobacter*) I, II, III, Gruber. From sugar solutions undergoing butyric fermentation. Source of inoculum not stated. (III is probably not strictly anaerobic.)

Clostridium butyricum iodophilum Svartz. From human feces.

Clostridium intermedium Donker. From retting flax.

Clostridium polyfermenticum Partansky and Henry. From mud of streams and lakes and from soil.

Clostridium saccharobutyricum Donker. From various farinaceous materials and from soil.

Clostridium saccharopetum Partansky and Henry. From mud of streams and lakes and from soil.

Clostridium saccharophilicum Partansky and Henry. From mud of streams and lakes and from soil.

Clostridium saccharopostulatum Partansky and Henry. From mud of streams and lakes and from soil.

Clostridium tyrobutyricum van Beynum and Pette. From soil, water, milk, cheese and various farinaceous materials. Widely dispersed in nature.

Ferment butyrique (Vibrion butyrique) Pasteur. Cultivated and presumably isolated from sugar solutions undergoing butyric fermentation after inoculation with yeast. Purity of cultures seriously questioned.

Granulobacillus saccharobutyricus mobilis non-liquefaciens Schattenfroh and Grassberger. From milk and from soil.

Granulobacter butylicum Beijerinck. From fermenting grain mash and from soil.

Granulobacter saccharobutyricum Beijerinck. From fermenting grain mash and from soil.

Granulobacter saccharobutyricus immobile nonliquefaciens McCoy et al. Source of isolation not recorded.

Plectridium pectinovorum Störmer. From retting flax and hemp. Probably not strictly anaerobic.

1b. **Clostridium pasteurianium** Winogradsky.

Bacillus azoticus, *Bacillus dulcitofermentans*, *Bacillus inulofugus*, *Bacillus nonpentosus* and *Bacillus rhamnoticus* Bodily. Source of isolation not specified, other than from cultures received from various sources labeled *C. pasteurianum*.

6. **Clostridium septicum** Ford.

Bacillus tumefaciens Wilson. From human gaseous gangrene.

Bradsotbacillus, Nielsen. From tissues and organs of sheep dying of braxy.

Walfischseptikämie Bacillus, Nielsen. From whales evidently dead of septicemia resulting from harpoon wounds.

9. **Clostridium novyi** Bergey et al.

Bacille neigeux, Jungano. From a human case of fetid cystitis, from abscess of kidney, and from various perineal infections.

Bacillus bellonensis Sacquépée. From human gaseous gangrene.

Bacillus gigas Zeissler and Rassfeld. From tissues of a sheep dying of a braxy-like disease.

Bacillus oedematiens Weinberg and Seguin. From human gaseous gangrene.

Clostridium bubalorum Prévot. Isolated, but not named, by Kraneveld from cases of osteomyelitis of the East Indian buffalo.

Gasödembazillus, Aschoff. From human gaseous edema resulting from war wounds.

11. **Clostridium acetobutylicum** McCoy et al.

Bacillus butylaceticum Freiberg. From grains, soil and natural waters. Widely distributed in nature.

Bacillus butylicus B. F., Ricard. From drains from slaughter houses.

Bacillus saccharobutyricus liquefaciens McCoy et al. Source of isolation unknown; records only from the collection of the Dept. Agric. Bact. of the Univ. of Wis. Received from a commercial laboratory.

Butylobacter betae Bakonyi. From beets (*Beta vulgaris*) contaminated with soil.

Butylobacter sinense Bakonyi. From Jaffa oranges.

Butylobacter solani Bakonyi. From German potatoes.

Butylobacter zeae Bakonyi. From Hungarian maize.

Clostridium butyricum (*Prazmowski-Pike-Smyth*) Pike and Smyth. From spontaneously fermenting corn meal mash.

Clostridium inverto-acetobutylicum Legg and Stiles. From soil and from plant materials in contact with soil.

Clostridium propyl-butylicum Muller and Legg. From soil and from plant materials in contact with soil.

Clostridium saccharo-acetobutylicum Stiles and Legg. From soil and from plant materials in contact with soil.

Clostridium saccharo-acetobutylicum-alpha McCoy. From soil.

Clostridium saccharo-acetobutylicum-beta Arzberger. From soil, rotten wood, grain, cornstalks and river mud.

Clostridium saccharo-acetobutylicum-gamma Arzberger. From soil, rotten wood, grain, corn stalks and river mud.

Clostridium saccharobutyl-acetonicum Loughlin. From potato; found in soil and on plant materials grown in or near soil.

Clostridium saccharobutylicum-gamma Izsak and Funk. From rice.

Clostridium saccharobutyl-isopropyl-acetonicum Loughlin. From potatoes, grains and other plant materials grown in or above soil.

Clostridium (Bacillus) tetrylium Owen, Mobley and Arroyo. From soil and from roots of sugar cane.

13. **Clostridium sporogenes** Bergey et al.

Bacillus putrificus verrucosus Zeissler. From animals suffering from a Rauschbrandlike infection; later from gangrenous war wounds.

Bacillus saprogenes carnis Salus. From human feces by enrichment in meat mash medium.

Bacillus sporogenes coagulans Debono. From normal human intestine.

Paraplectrum foetidum Weigmann. From cheese and milk.

Reading Bacillus, Donaldson and Joyce. From gangrenous human war wounds.

20. **Clostridium bifermentans** Bergey et al.

Bacillus centrosporogenes Hall. From a sterility test of tuberculin, from canned spinach and from garden soil.

Bacillus liquefaciens magnus Lüderitz. From mice and guinea pigs inoculated with garden soil.

Bacillus nonfermentans Hall and Whitehead. From poisoned African arrowheads.

Bacillus oedematis sporogenes Sordelli. From human gaseous gangrene.

Bacillus putrificus tenuis Zeissler. From malignant edema of various animals and from human gaseous gangrene.

Bacillus sporogenes foetidus Chouké-vitch. From large intestine of horse.

Clostridium foetidum Liborius. From mice inoculated with garden soil.

Clostridium foetidum carnis Salus. From human feces by enrichment in meat mash medium.

Clostridium oedematoides Meleney, Humphreys and Carp. From a case of human post-operative gaseous gangrene.

24. **Clostridium perfringens** Holland.

Bacille du rhumatisme, Achalme. Isolated by blood culture from human cases of acute articular rheumatism.

Bacillus amylobacter immobilis Gratz and Vas. From Liptauer cheese.

Bacillus cadaveris Sternberg. From liver and kidney of a yellow fever cadaver.

Bacillus cadaveris butyricus Buday. From organs of human cadavers undergoing postmortem emphysema.

Bacillus egens Stoddard. From muscle in a fatal case of human gaseous gangrene.

Bacillus emphysematis maligni Wicklein. From human gaseous gangrene.

Bacillus emphysematis vaginae Lindenthal. From human kolpohyperplasia cystica or vaginitis emphysematosa.

Bacillus multiformis Distaso. From feces of dog.

Bacillus ovitoxicus Bennetts. From blood, tissues and organs of sheep in Australia dying of entero-toxemia.

Bacillus paludis McEwen. From intestines and viscera of sheep in the Romney Marsh in England suffering from a disease called struck.

Bacillus perfringens Veillon and Zuber. Originally isolated from pus in human appendicitis; later from a variety of sources.

Bacillus phlegmones emphysematosae Fraenkel. From human gaseous phlegmons; later from a variety of related conditions of human beings and animals.

Bacillus zoodysentriae hungaricus Detre. Isolated in Hungary from intestines of diarrheal pigs and lambs.

Clostridium perfringens var. *anaerogenes* Hauduroy et al. An unnamed culture isolated by Grooten by blood culture from a fatal human septicemia.

Granulobacillus saccharobutyricus immobilis liquefaciens Schattenfroh and Grassberger. Originally isolated from market milk; later from cheese, soil, water, human and animal feces, and from various grain meals.

29. **Clostridium paraputrificum** Snyder.

Bacillus innutritus Kleinschmidt. From stools of newborn infants.

Plectridium fluxum Prévot. From feces of nursing newborn infants.

Plectridium nonum Prévot. From emphysematous muscle of an amputated human arm.

41. **Clostridium lentoputrescens** Hartsell and Rettger.

Bacillus cadaveris sporogenes (*anaerobicus*) Klein. From normal intestines of man and animals.

Bacillus radiatus Lüderitz. From mice and guinea pigs inoculated with garden soil.

Bacillus tetanoides (*B*) Adamson. From human septic and gangrenous war wounds.

43. **Clostridium tetanomorphum** Bergey et al.

Bacillus fragilis Veillon and Zuber. From human cases of purulent appendicitis.

Bacillus ramosus Veillon and Zuber. From human cases of purulent appendicitis and from pulmonary gangrene.

45. **Clostridium angulosum** Hauduroy et al.

Bacillus angulosus Garnier and Simon. From blood of a child suffering from typhoid fever.

61. **Clostridium tertium** Bergey et al. *Bacillus aero-tertius* Bulloch et al. Isolated from gangrenous human war wounds. Stated to be aerobic.

Bacillus gazogenes parvus Choukévitch. From large intestine of horse.

Bacillus spermoide Ninni. From soil.

Suborder II. Caulobacteriineae Breed, Murray, and Hitchens.*

(*Caulobacteriales* Henrici and Johnson, Jour. Bact., *29*, 1935, 3; *ibid.*, *30*, 1935, 83; Breed, Murray and Hitchens, Bact. Rev., *8*, 1944, 255.)

Non-filamentous, attached bacteria growing characteristically upon stalks, sometimes sessile. The stalked cells are asymmetrical in that gum, ferric hydroxide or other material is secreted from one side or one end of the cell to form the stalk. Multiply by transverse fission. In some species the stalks are very short or absent. In the latter case the cells may be attached directly to the substrate in a zoogloeic mass. Cells occur singly, in pairs or short chains, never in filaments; not ensheathed. Non-spore-forming. Typically aquatic in habitat.

Key to the families of suborder **Caulobacteriineae.**

I. Long axis of cell transverse to long axis of stalk; stalks dichotomously branched
  A. Stalks lobose, composed of gum, forming zoogloea-like colonies.
    Family I. *Nevskiaceae*, p. 830.
  B. Stalks are bands of ferric hydroxide.
    Family II. *Gallionellaceae*, p. 830.
II. Long axis of cell coincides with axis of stalk.
  A. Reproducing by transverse fission, stalks unbranched.
    Family III. *Caulobacteriaceae*, p. 832.
III. Sessile, capsulated colonies of cocci and short rods attached to water plants.
  A. Deposit of ferric hydroxide about a zoogloeic mass.
    Family IV. *Siderocapsaceae*, p. 833.

As a result of discussions that have taken place since the fifth edition of the Manual was issued, certain readjustments have been made in the arrangement of the stalked bacteria. The organisms in all of the typical species are simple rigid bacteria which are like ordinary bacteria except that they develop a stalk. For this reason the group has been made a suborder of the order *Eubacteriales*.

Stanier and Van Niel (Jour. Bact., *42*, 1941, 454) emphasize the fact that the family *Pasteuriaceae* includes species which reproduce by methods (longitudinal fission, budding) different from those found in other groups of bacteria, and Henrici and Johnson (*loc. cit.*, 81) state that it is at least doubtful whether these species are phylogenetically related to the other stalked bacteria. While waiting for pure culture studies and a clarification of these relationships, this family has been placed in an appendix to the suborder *Caulobacteriineae.*

The family *Siderocapsaceae* has been included in the suborder as the absence of a stalk in attached forms is a natural modification. As stated by Cholodny (Die Eisenbakterien, Jena, 1926, 34–58), these bacteria are similar in morphology and physiology to those found in the family *Gallionellaceae.* This is an arrangement that retains all of the simple non-filamentous types of iron bacteria in one general group.

The stalked bacteria studied by Henrici and Johnson (*loc. cit.*) were of fresh water origin. Bacteria of this type are found, however, equally if not more abundantly in marine habitats where they play their part in starting the fouling of underwater surfaces. ZoBell and Upham (Bull. Scripps Inst. Oceanography, La Jolla, Cali-

* Completely revised by Prof. A. T. Henrici, University of Minnesota, Minneapolis, Minnesota, December, 1938; further revision by Prof. Robert S. Breed, New York State Experiment Station, Geneva, New York, July, 1946.

fornia, *5*, 1944, 253) summarize this situation as follows: "Many of the bacteria found in sea water are sessile or periphytic, growing preferentially or exclusively attached to solid surfaces. The sessile habit of marine bacteria is most pronounced when they are growing in very dilute nutrient solutions such as sea water to which nothing has been added. . . . Most sessile bacteria appear to attach themselves tenaciously to solid surfaces by exuding a mucilaginous holdfast. A few have stalks. Some of the sessile bacteria grow on the walls of the culture receptacle without clouding the medium itself".

The emphasis placed on the presence of a stalk by Henrici and Johnson (*loc. cit.*) seems artificial. In fact it may be questioned whether mere attachment by a holdfast or otherwise is a character of fundamental importance from the taxonomic standpoint. Henrici and Johnson's arrangement of these poorly known bacteria, however, has certain practical advantages and it has therefore been retained in this edition of the MANUAL with such modifications as seem to be clearly indicated by the progress that has been made since their outline was published.

The submerged slide technique as employed by Henrici (Jour. Bact., *25*, 1933, 277) and by ZoBell and Allen (Proc. Soc. Exper. Biol. and Med., *30*, 1933, 1409) has proved to be most useful for studying bacteria that live attached to a substrate.

FAMILY I. NEVSKIACEAE HENRICI AND JOHNSON.

(Jour. Bact., *29*, 1935, 4; *ibid.*, *30*, 1935, 83.)

Stalked bacteria, the long axis of the rod-shaped cells being set at right angles to the axis of the stalk. Stalks lobose, dichotomously branched, composed of gum. Multiplication of cells by transverse binary fission. Growing in zoogloea-like masses in water or in sugar vats.

There is a single genus *Nevskia*.

Genus I. **Nevskia** *Famintzin.*

(Bul. Acad. Imp. Sci., St. Pétersb., *34*, N.S. *2*, 1892, 484.) From the Neva River at St. Petersburg.

Description as for the family.

The type species is *Nevskia ramosa* Famintzin.

1. **Nevskia ramosa** Famintzin. (Bul. Acad. Imp. Sci., St. Pétersb., Ser. IV, *34*, N.S. *2*, 1892, 484.) From Latin *ramosus*, branched.

Globular, bush-like or plate-like colonies of gummy consistency floating upon the surface of water. Colonies composed of gummy material arranged in dichotomously branched stalks arising from a common base, with the bacterial cells contained in the gum, a single cell at the tip of each stalk. At times cells are set free from the stalks to start new colonies.

Rod-shaped cells set with their long axis at right angles to the axis of the broad lobe-like stalk. Cells 2 by 6 to 12 microns, containing a number of highly refractile globules of fat or sulfur.

Multiplication by binary fission. Not cultivated on artificial media.

Source: From the aquarium in the Botanical Garden, St. Petersburg. Similar but smaller organisms found by Henrici and Johnson (Jour. Bact., *30*, 1935, 63) in a jar of water from the lily pond of the University of Minnesota greenhouse in Minneapolis.

Habitat: Water.

2. **Nevskia pediculata** (Koch and Hosaeus) Henrici and Johnson. (*Bacterium pediculatum* Koch and Hosaeus, Cent. f. Bakt., *16*, 1894, 225; Henrici and Johnson, Jour. Bact., *30*, 1935, 83.) From Latin *pediculus*, diminutive of *pes*, foot.

Composed of twisted, short, thick, sausage-like strands, often branched. These strands are stalks, composed of gum.

The cells occur at the tips of the stalks and are smaller than those of *Nevskia ramosa* and are without internal globules. Not cultivated.

This organism is very similar to, and may be identical with, the cultivated species described and named *Betabacterium vermiforme* by Mayer (Das Tibi-Konsortium. Thesis, Utrecht, 1938). See p. 362.

Source: Found growing in the syrup of a sugar refinery as zoogloeae.

FAMILY II. GALLIONELLACEAE HENRICI AND JOHNSON.

(Jour. Bact., *29*, 1935, 4; *ibid.*, *30*, 1935, 83.)

Stalked bacteria, the long axis of the rod-shaped cells being set at right angles to the axis of the stalks. Stalks are slender, twisted bands, dichotomously branched, composed of ferric hydroxide, completely dissolving in dilute hydrochloric acid. Multiplication of cells by transverse binary fission. Grow in iron-bearing waters.

There is a single genus *Gallionella*.

Genus I. **Gallionella** *Ehrenberg.*

(Ehrenberg, Die Infusionsthierchen, 1838, 166; not *Gaillonella* Bory de St. Vincent, Dict. Classique d'Hist. Nat., *4*, 1823, 393; *Gloeotila* Kützing, Phycologia Generalis, 1843, 245; *Didymohelix* Griffith, Ann. Mag. Nat. Hist., Ser. 2, *12*, 1853, 438; *Spirophyllum* Ellis, Cent. f. Bakt., II Abt., *19*, 1907, 502; *Nodofolium* Ellis, Proc. Roy. Soc. Edinburgh, *28*, Part 5, 1908, 339.) From an incorrect spelling of the algal genus name, *Gaillonella*.

Description as for the family.

The type species is *Gallionella ferruginea* Ehrenberg.

Key to the species of genus Gallionella.

I. Cells kidney-shaped; stalks branched.
  A. Stalks slender, spirally twisted.
    1. Cells small, stalks very slender.
      1. *Gallionella ferruginea.*
    2. Cells larger, stalks broader.
      2. *Gallionella major.*
  B. Stalks thick, not definitely in spirals.
      3. *Gallionella minor.*
II. Cells oval or round; stalks unbranched.
      4. *Gallionella corneola.*

1. **Gallionella ferruginea** Ehrenberg. (*Gaillonella ferruginea* Ehrenberg, Vorl. Mittheil. ü. d. wirkl. Vorkommenn fossiler Infusionen u. ihre grosse Verbreitung, Ann. Phys., Ser. 2, *8*, 1836, 217; Ehrenberg, Die Infusionsthierchen, 1838, 166; *Melosira ochracea* Ralfs, Ann. and Mag. Nat. His., Ser. 1, *12*, 1843, 351 (quoted from Buchanan, General Systematic Bacteriology, 1925, 363); *Gloeotila ferruginea* Kützing, Species Algarum, 1849, 363; *Didymohelix ferruginea* Griffith, Ann. Mag. Nat. Hist., Ser. 2, *12*, 1853, 438; *Gloeosphaera ferruginia* Rabenhorst, Alg. Mitteleur., no. 387; Hedwigia, *8*, no. 9, 1854, 43; *Melosira minutula* Breb., Alg. Fal., *5*, 42 (quoted from DeToni and Trevisan, see below); *Spirulina ferruginea* Kirchner, Algen, Kryptogamenflora v. Schlesien, *2*, 1, 1878, 250; *Spirochaete ferruginea* Hansgirg, Oestr. botan. Ztschr., no. 7–8, 1888, 5; *Spirillum ferrugineum* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1007; *Chlamydothrix ferruginea* Migula, Syst. d. Bakt., *2*, 1900, 1031; *Spirophyllum ferrugineum* Ellis, Cent. f. Bakt., II Abt., *19*, 1907, 502; *Spirophyllum tenue*, *Nodofolium ferrugineum*, *Spirosoma ferrugineum* and *Spirosoma solenoide* Ellis, Proc. Roy. Soc. Edinburgh, *28*, Part 5, 1908, 341; also see Cent. f. Bakt., II Abt., *26*, 1910, 321; *Gallionella taeniata* Enderlein, Bakterien-Cyclogenie, Berlin and Leipzig, 1925, 252.) From Latin *ferruginus*, iron rust.

Kidney-shaped bacteria, the cells 0.5 by 1.2 microns, which secrete colloidal ferric hydroxide from the concave portion of the cell, forming band-like stalks. A rotatory motion of the cells gives rise to a spiral twisting of the stalks.

In the older studies, the stalks were described as the organism, the minute cells at the tip having been dislodged or at least overlooked. The cells lie at the tip of the stalk, and multiply by transverse binary fission. This gives rise to a dichotomous branching of the stalks. Stalks become very long and slender, with smooth edges.

Not cultivated in artificial media.

Habitat: Cool springs and brooks which carry reduced iron in solution.

2. **Gallionella major** Cholodny. (Trav. Station. biolog. du Dniepre Acad. des Sci. de l'Ukraine, Classe Sci. Phys. et Math., *3*, Livre 4, 1927.) From Latin *major*, larger.

Very similar to *Gallionella ferruginea*, but the cells are distinctly larger (1 by 3 microns), and, some cells failing to divide, reach a length of 7 microns or more. These form stalks of double the normal width.

The cells contain one or more vacuoles, apparently filled with an iron compound.

Source: Found in a spring in the Caucasus.

Habitat: Iron-bearing water.

3. **Gallionella minor** Cholodny. (Ber. d. deutsch. Bot. Ges., *42*, 1924, 35.) From Latin *minor*, smaller.

Cells as in *Gallionella ferruginea*, but stalks are shorter, thicker, encrusted with nodules of iron and not definitely band-like or twisted.

Habitat: Iron-bearing water.

4. **Gallionella corneola** Dorff. (Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 25.) From Latin *corneolus*, a little horn.

Cells spherical or ellipsoidal, or lenticular in cross section, 0.5 by 2.5 to 3.0 microns.

Stalks short, unbranched, not spirally twisted, completely dissolving in dilute hydrochloric acid. Stalks slender at the base, expanded at the tip, slightly curved, 15 to 30 microns long, attached to the substrate by a holdfast, 3 to 8 stalks arising from a single holdfast.

Habitat: Iron-bearing water.

Appendix: Additional species of *Gallionella* have been described as follows:

Gallionella glomerata described by Naumann (Kungl. Svenska Vetenskapsakad. Handl., I, *62*, 1921, Part 4, 45) is not a valid species according to Cholodny (Die Eisenbakterien, Jena, 1926, 40). From the Aneboda region, Sweden.

Gallionella reticulosa Butkevich. (Ber. d. Wiss. Meeresinst. Moscow, *3*, 1928, 58 and 80.) From the White Sea.

Gallionella sideropous described by Naumann (Kungl. Svenska Vetenskapsakad. Handl., I, *62*, 1921, Part 4, 33) is not a valid species, according to Cholodny (Die Eisenbakterien, Jena, 1926, 39). From the Aneboda region, Sweden.

Gallionella tortuosa Butkevich. (Ber. d. wiss. Meeresinst. Moscow, *3*, 1928, 57 and 79.) From the Petschora Sea.

FAMILY III. CAULOBACTERIACEAE HENRICI AND JOHNSON.

(Jour. Bact., *29*, 1935, 4; *ibid.*, *30*, 1935, 83.)

Stalked bacteria, the long axis of the elongated cells coinciding with the long axis of the stalks. Stalks are slender, flagellum-like, often attached to the substrate by a button-like holdfast, unbranched. Multiplication of cells by transverse binary fission. The outermost cell of a pair may form a stalk before cell division is complete. Periphytic, growing upon submerged surfaces.

There is a single genus *Caulobacter*.

Genus I. Caulobacter *Henrici and Johnson.*

(Jour. Bact., *29*, 1935, 4; *ibid.*, *30*, 1935, 83.) From Latin *caulis*, stalk and *bacter*, a small rod.

Description as for the family.

The type species is *Caulobacter vibrioides* Henrici and Johnson.

1. **Caulobacter vibrioides** Henrici and Johnson. (Jour. Bact., *30*, 1935, 84.) From Latin, like a vibrio.

Cells elongated, curved, vibrio-like, with rounded ends, 0.7 to 1.2 by 2.0 to 2.5 microns.

Growing upon firm substrates in water. Not cultivated on artificial media.

Habitat: Water.

Appendix: Henrici and Johnson (Jour. Bact., *30*, 1935, 62) list the following as possibly belonging in this genus:

Bacillus flagellatus Omeliansky. (Jour. Microbiol. (Russian), *1*, 1914, 24.) Probably the same as the organism described by Jones (Henrici and Johnson, *loc. cit.*, 62).

Polar flagellate organism, Jones. (Cent. f. Bakt., II Abt., *14*, 1905, 459.) From water and sewage.

Vibriothrix tonsillaris Tunnicliff and Jackson. (Tunnicliff and Jackson, Jour. Inf. Dis., *46*, 1930, 12; see Henrici and Johnson, *loc. cit.*, 62.) From tonsil crypts. See p. 219 for a different viewpoint regarding this species.

Six additional types are figured but not named by Henrici and Johnson (*loc. cit.*, 84).

FAMILY IV. SIDEROCAPSACEAE PRIBRAM.

(Tribe *Siderocapseae* Buchanan, Jour. Bact., *2*, 1915, 615; Pribram, Jour. Bact., *18*, 1929, 377.)

Cells spherical or ovoid. Motile stages, if any, unknown. Not yet cultivated on artificial media. Thick capsules enclosing the cells become encrusted with ferric hydroxide. Attached to the surface of leaves and other parts of water plants.

Key to the genera of family **Siderocapsaceae.**

I. Cocci, occurring singly and in groups, and embedded in small irregular gelatinous masses.

Genus I. *Siderocapsa*, p. 833.

II. Coccobacteria, occurring in chains, and embedded in large gelatinous masses.

Genus II. *Sideromonas*, p. 834.

Genus I. **Siderocapsa** *Molisch.*

(Ann. Jard. Bot. Buitenzorg, 2 Sér., Supp. 3, 1909, 29; also Die Eisenbakterien, Jena, 1910, 11.) From Greek *sideros*, iron and Latin *capsa*, box.

One to many spherical to ovoid small cells embedded in a mass of capsular material surrounded by ferric hydroxide. Best recognized by staining with Schiff's reagent. Motility unknown. Grow attached to the surface of water plants.

The type species is *Siderocapsa treubii* Molisch.

1. **Siderocapsa treubii** Molisch. (Ann. Jard. Bot. Buitenzorg, 2 Sér., Supp. 3, 1909, 29; also Die Eisenbakterien, Jena, 1910, 11.) Named for Prof. Treub, the director of the tropical garden at Buitenzorg, Java.

Cocci: 0.4 to 0.6 micron in diameter embedded in zoogloeal masses surrounded by ferric hydroxide.

Deposit ferric hydroxide on the surfaces of water plants.

Source: Found attached to the roots, root hairs and leaves of water plants (*Elodea*, *Nymphaea*, *Sagittaria*, *Salvinia*, etc.).

Habitat: Widely distributed, on fresh water plants.

2. **Siderocapsa major** Molisch. (Ann. Jard. Bot. Buitenzorg, 2 Sér., Supp. 3, 1909, 29; also Die Eisenbakterien, Jena, 1910, 13.) From Latin *major*, larger.

Cells colorless, coccus-like short rods, 0.7 by 1.8 microns. A colony consists of 2 to 100 or more cells.

Similar to *Siderocapsa treubii*, except

that the cells are larger and the gelatinous capsule is less sharply defined.

Source: Isolated from *Spirogyra sp.*

Habitat: Epiphytic on fresh water plants.

Appendix: Two additional species have been placed in the genus *Siderocapsa* by later investigators:

Siderocapsa coronata Redinger. (Arch. f. Hydrobiol., *22*, 1931, 410.) From lake water. A free floating form.

Siderocapsa monoica Naumann. (Kungl. Svenska Vetenskapsakad. Handl., I, *62*, 1921, Part 4, 49; quoted from Cholodny, Die Eisenbakterien, Jena, 1926, 59.) Found on *Potamogeton natans* in Sweden. Cells occur singly.

Genus II. Sideromonas *Cholodny.*

(Ber. d. deutsch. Bot. Ges., *40*, 1922, 326; also Die Eisenbakterien, Jena, 1926, 55.) From Greek *sideros*, iron and *monas*, a unit.

Small cocci or coccobacteria which grow in chains in gelatinous masses containing ferric hydroxide attached to thread algae, generally of the genus *Conferva*.

The type species is *Sideromonas confervarum* Cholodny.

1. **Sideromonas confervarum** Cholodny. (Ber. d. deutsch. Bot. Ges., *40*, 1922, 326; also Die Eisenbakterien, Jena, 1926, 55; *Siderocystis confervarum* Naumann, quoted from Dorff, Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 13.) From Latin, of the genus *Conferva*.

Coccobacteria: 0.5 to 0.6 by 0.8 to 0.9 micron, occurring in chains embedded in gelatinous masses, 10 to 100 microns in diameter. Chains become visible when the gelatinous mass is treated with formalin followed by dilute HCl, washed in water, and stained with gentian violet or carbol fuchsin. No motility observed.

Form deposits of ferric hydroxide in the gelatinous mass surrounding the bacteria.

Source: Found on the surface of thread algae in water containing iron salts.

Habitat: Widely distributed on fresh water green algae.

Appendix: Additional species of simple, sessile, non-filamentous bacteria which cause deposits of ferric hydroxide have been described. The majority are rod-shaped bacteria and resemble *Sideromonas*. The list follows:

Ferribacterium calceum Brussoff. (Brussoff, Cent. f. Bakt., II Abt., *48*, 1918, 208; *Siderobacter calceum* Naumann, Kungl. Svenska Vetenskapsakad. Handl., I, *62*, Part 4, 1921, 53 and 63; *Bacillus calceus* De Rossi, Microbiol. Agraria e Technica, Torino, 1927, 903.) From slime in drainage ditches at Aachen.

Ferribacterium duplex Brussoff. (Brussoff, Cent. f. Bakt., II Abt., *45*, 1916, 547; *Sideroderma duplex* Naumann, Kungl. Svenska Vetenskapsakad. Handl., I, *62*, Part 4, 1921, 53 and 63; *Bacterium duplex* De Rossi, Microbiol. Agraria e Technica, Torino, 1927, 903.) A non-motile, diplobacterium from water samples from Breslau (Schwentniger and Pirschamer).

Naumanniella minor Dorff. (Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 21.) From iron-bearing spring water at Worms (Rhein).

Naumanniella neustonica Dorff. (Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 20.) From Neuston on Tuefelsee near Freienwalde. Dorff (*loc. cit.*) indicates this species as the type for a new genus *Naumanniella*.

Siderobacter duplex Naumann. (Kungl. Svenska Vetenskapsakad. Handl., I, *62*, Part 4, 1921, 55.) From Aneboda region, Sweden.

Siderobacter lineare Naumann (*loc. cit.*, 55). From Aneboda region, Sweden. The type species of the genus *Siderobacter*.

Siderococcus communis Dorff. (Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 11.) Widely distributed in Germany, Finland, Russia, Sweden, Czechoslovakia and the U. S. A.

Siderococcus limneticus Dorff (*loc. cit.*). From a swamp iron ore deposit. This is the type species of the genus *Siderococcus* Dorff (*loc. cit.*).

Siderocystis duplex Naumann. (Kungl. Svenska Vetenskapsakad. Handl., I, *62*, Part 4, 1921, 43.) From Aneboda region, Sweden.

Siderocystis minor Naumann (*loc. cit.*, 43). From Aneboda region, Sweden.

Siderocystis vulgaris Naumann (*loc. cit.*, 42). From Aneboda region, Sweden. The type species of the genus *Siderocystis*.

Sideroderma limneticum Naumann. (Kungl. Svenska Vetenskapsakad. Handl., I, *62*, Part 4, 1921, 32; *Ochrobium tectum* Perfiliev, Verh. d. Internat. Vereinigung f. theoret. u. angew. Limnologie, 1925, Stuttgart, 1927; quoted from Dorff, Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 18.) From Aneboda region, Sweden. The type species of the genus *Sideroderma*. Perfiliev regards this species as type for a new genus, *Ochrobium*.

Sideroderma rectangulare Naumann (*loc. cit.*, 54). From Aneboda region, Sweden.

Sideroderma tenue Naumann (*loc. cit.*, 54). From Aneboda region, Sweden.

Siderothece major Naumann. (Kungl. Svenska Vetenskapsakad. Handl., I, *62*, Part 4, 1921, 17.) From Aneboda region, Sweden. The type species of the genus *Siderothece*.

Siderothece minor Naumann (*loc. cit.*, 17). From Aneboda region, Sweden.

APPENDIX TO SUBORDER CAULOBACTERIINEAE.

The family *Pasteuriaceae* included among the stalked bacteria by Henrici and Johnson (*loc. cit.*) has been placed in this appendix as the organisms belonging to the genera *Pasteuria* and *Blastocaulis* reproduce by methods of fission or budding, or both, that are different from the methods of reproduction found in other bacteria. Further information regarding the organisms in these genera is greatly needed.

FAMILY A. PASTEURIACEAE LAURENT EMEND. HENRICI AND JOHNSON.

(Laurent, Compt. rend. Acad. Sci., Paris, *3*, 1890, 754; Henrici and Johnson, Jour. Bact., *30*, 1935, 84.)

Stalked bacteria with spherical or pear-shaped cells; if cells are elongated, long axis of cell coincides with axis of stalk. Stalks may be very short or absent, but when present are usually very fine and at times arranged in whorls attached to a common holdfast. Cells multiply by longitudinal fission or by budding, or by both. Mostly periphytic, one species is parasitic.

Key to the genera of family **Pasteuriaceae.**

I. Stalks lacking, cells sessile.

Genus I. *Pasteuria*, p. 836.

II. Stalks long and slender, often in whorls.

Genus II. *Blastocaulis*, p. 836.

Genus I. **Pasteuria** *Metchnikoff.*

(Ann. Inst. Past., *2*, 1888, 166.) Named for Louis Pasteur, the French chemist and bacteriologist.

Pear-shaped cells attached to each other or to a firm substrate by holdfasts secreted at the narrow end, multiplying by longitudinal fission and by budding of spherical or ovoid cells at the free end.

The type species is *Pasteuria ramosa* Metchnikoff.

1. **Pasteuria ramosa** Metchnikoff. (Ann. Inst. Past., *2*, 1888, 465.) From Latin *ramosus*, branched.

Cells grow attached to each other in cauliflower-like masses, multiplying by longitudinal fission and by intracellular spores (?) which are extruded as bud-like bodies.

Habitat: Parasitic in the body cavities of *Daphnia pulex* and *Daphnia magna.*

Genus II. **Blastocaulis** *Henrici and Johnson.*

(Jour. Bact., *30*, 1935, 84.) From Greek *blastos*, bud, germ and Latin *caulis*, stalk.

Pear-shaped or globular cells attached to a firm substrate by long slender stalks with a holdfast at the base. Stalks may occur singly or may arise in clusters from a common holdfast. Growing on firm substrates in fresh water. Not cultivated on artificial media.

The type species is *Blastocaulis sphaerica* Henrici and Johnson.

1. **Blastocaulis sphaerica** Henrici and Johnson. (Jour. Bact., *30*, 1935, 84.) From Latin *sphaera*, sphere.

Cells spherical, multiplying characteristically by budding, often staining deeply at the free pole and faintly at the attached pole, 1 to 2 microns in diameter.

Habitat: Water.

Appendix: Henrici and Johnson (*loc. cit.*, 84) figure but do not name four additional types of these organisms which they regard as additional species belonging to this genus.

Stanier and Van Niel (Jour. Bact., *42*, 1941, 454) regard the following as belonging to this group:

Hyphomicrobium vulgare Stutzer and Hartleb. (Saltpeterpilz, Stutzer and Hartleb, Cent. f. Bakt., II Abt., *3*, 1897, 621; Stutzer and Hartleb, Untersuchungen über die bei der Bildung von Saltpeter beobachteten Mikroorganismen, I Abt. Mittheil. landwirtsch. Inst. Univ. Breslau, 1898, abst. in Cent. f. Bakt., II Abt., *5*, 1899, 678.) From tap water and soil. The position of this organism in relation to other *Schizomycetes* is very uncertain. It is regarded by Boltjes (Arch. f. Mikrobiol., 7, 1936, 188) as an organism which may be transitional between *Schizomycetes* and *Phycomycetes*. The cells possess structures which appear to be polar flagella; but with dark field illumination show an attached thread of ultramicroscopic size. Reproduction by cell division was not observed. Possibly this may be by budding from the attached thread. Associated with *Nitrobacter spp.* This is the type species of the genus *Hyphomicrobium* Stutzer and Hartleb.

Suborder III. Rhodobacteriineae Breed, Murray and Hitchens.*

(Family *Rhodobacteriaceae* Migula, Syst. d. Bakt., *2*, 1900, 1042; Breed, Murray and Hitchens, Bact. Rev., *8*, 1944, 257.)

Cells spherical, rod-, vibrio-, or spiral-shaped. Size of individual cells from less than 1 to over 20 microns. Motility, when exhibited, due to the presence of polar flagella. Gram-negative so far as known. No endospores formed. Red, purple, brown or green bacteria which contain bacteriochlorophyll or other chlorophyll-like green pigments, and usually also possess one or more carotenoid pigments. Capable of carrying out a photosynthetic metabolism which differs from that of green plants in that it does not proceed with the evolution of oxygen, and depends upon the presence of extraneous oxidizable compounds which are dehydrogenated with the simultaneous reduction of carbon dioxide. As oxidizable substrates a variety of simple substances can be used, such as sulfide, or other reduced sulfur compounds, molecular hydrogen, alcohols, fatty acids, hydroxy- and keto-acids, etc. All can be grown in strictly anaerobic cultures when illuminated. Those members which can grow in the presence of air can also be cultured in the dark under aerobic conditions. Color depends markedly on environmental conditions; small individuals appear colorless unless observed in masses. May contain sulfur globules. Described species have largely been found in fresh water habitats. Some species occur in marine habitats.

Key to the families of suborder **Rhodobacteriineae.**

I. Purple bacteria whose pigment system consists of bacteriochlorophyll and various carotenoids capable of carrying out a photosynthetic metabolism.
   A. Contain sulfur globules in the presence of hydrogen sulfide. The sulfur purple bacteria.
      Family I. *Thiorhodaceae*, p. 841.
   B. Do not contain sulfur globules even in the presence of hydrogen sulfide. All require organic growth factors. The non-sulfur purple and brown bacteria.
      Family II. *Athiorhodaceae*, p. 861.

II. Green sulfur bacteria containing a pigment system which has the characteristics of a chlorophyllous compound although it differs from the chlorophyll of green plants and from the bacteriochlorophyll of the purple bacteria.
      Family III. *Chlorobacteriaceae*, p. 869.

The organisms previously included in the order *Thiobacteriales* Buchanan do not constitute a taxonomic entity; they represent rather a physiological-ecological community. In this sense, however, a special treatment of this group as a unit has decided advantages from a determinative point of view.

When first proposed as a systematic assemblage, the order *Thiobacteria* Migula (Syst. d. Bakt., *2*, 1900, 1039) was intended to include the morphologically conspicuous organisms which, in their natural habitat, contain globules of sulfur as cell inclusions. Since Winogradsky (Beitr. z. Morph. u. Physiol. d. Bact., I, Schwefelbacterien, 1888) had elucidated the function of hydrogen sulfide and of sulfur in their metabolism, the characteristic inclusions appeared linked with a hitherto unrecognized type of physiology, *viz.* the oxidation of an inorganic substance instead of the decomposition of organic materials. From this oxidation the sulfur bacteria derive their energy for maintenance and growth.

* Completely revised by Prof. C. B. van Niel, Hopkins Marine Station, Pacific Grove, California, January, 1944.

Two groups of sulfur bacteria could be distinguished, one consisting of colorless, the other of red or purple organisms. The members of both groups presented an unusual morphology apart from the sulfur droplets; in all cases the individual cells were considerably larger than those of the common bacteria, while many species grew as distinctive colonial aggregates. Migula separated these sulfur bacteria into two families, *Beggiatoaceae* and *Rhodobacteriaceae*. Even at that time, however, some difficulties existed as to just what organisms should properly be considered as sulfur bacteria. Miyoshi (Jour. Coll. Sci., Imp. Univ., Tokyo, *10*, 1897, 143) had discovered a bacterium which forms stringers, incrusted with sulfur, in sulfur springs, but which does not store sulfur globules in its cells. Although physiologically this organism appeared to comply with Winogradsky's concept of a sulfur bacterium, the absence of the typical cell inclusions made Miyoshi decide it could not be considered as such. The problem was aggravated when Nathansohn, Beijerinck, and Jacobsen published their studies on small, colorless, *Pseudomonas*-like bacteria capable of oxidizing hydrogen sulfide, sulfur, and thiosulfate, and evidently dependent upon this oxidation process for their development. Morphologically these organisms have little in common with the *Beggiatoaceae*; they were designated by Beijerinck as species of *Thiobacillus* and have since been rightly considered as members of the order *Eubacteriales* (see p. 78). Nevertheless, these organisms are physiologically in no way different from the *Beggiatoaceae*, so that if physiology only is considered, a good case could be made out for their incorporation in the *Thiobacteriales*.

Furthermore, Molisch (Die Purpurbakterien, Jena, 1907, 95 pp.) described in some detail a number of bacterial species which, in view of their characteristic pigment system, appeared closely related to the *Rhodobacteriaceae*, but which develop only in organic media and are, therefore, not sulfur bacteria in the sense of Winogradsky or Migula. In stressing the importance of pigmentation Molisch combined the red sulfur bacteria and the newly discovered purple bacteria into an order *Rhodobacteria* with the two families *Thiorhodaceae* and *Athiorhodaceae*. It is this grouping that has been followed in the present edition of the MANUAL.

Only a very small number of typical sulfur bacteria have been studied in pure cultures. As a result the descriptions of genera and species rest mainly on observations made with collections from natural sources or crude cultures. Most investigators have implicitly accepted differences in cell size or in colonial appearance as a sufficient justification for establishing independent species. Evidently this procedure presupposes a considerable degree of constancy of such characteristics in the organisms in question. It is true that Winogradsky's investigations have provided a reasonable basis for this belief, but later studies with pure cultures of certain purple bacteria have established beyond a doubt that environmental conditions, such as composition of the medium and temperature, may exert a profound influence on the general morphology of these organisms. By this, it is not intended to infer that the previously proposed genera and species of sulfur bacteria should be abandoned. But it does follow that a cautious evaluation of the distinguishing features is necessary. In the absence of carefully conducted investigations on morphological constancy and variability of most of the previously recognized species of sulfur bacteria with pure cultures grown under a variety of external conditions, the best approach appears to be a tentative arrangement of these organisms based upon those characteristics which are readily ascertainable. Experience with this group over the past twenty years has shown that, while Winogradsky's fundamental work must remain the foundation of present taxonomic efforts, it is advisable to simplify the much more elaborate classification developed by Buchanan which was followed in previous editions of this MANUAL.

Certain genera of sulfur purple bacteria, created by Winogradsky, will very probably be consolidated when detailed information concerning the morphology of the organisms is available. Until such time it seems, however, best to retain most of them, even though the distinguishing characteristics are not always very clear. For the benefit of those who are familiar with previous methods of classification it will be indicated where deviations have been adopted.

The non-sulfur purple bacteria (*Athiorhodaceae* Molisch; *Rhodobacterioideae* Buchanan) have been subjected to a comparative morphological and physiological study comprising more than 150 strains, among which all previously proposed genera and species are represented (Van Niel, Bact. Rev., *8*, 1944, 1–118). It has been found that the characteristics upon which Molisch based the seven genera of this group are inadequate, and a new classification with only two distinguishable genera has been proposed. This system will be followed here.

Nadson (Bull. Jard. Imper. Bot., St. Petersburg, *12*, 1912, 64) described a new type of small, green bacteria, not containing sulfur globules in the presence of hydrogen sulfide, but excreting elementary sulfur. These appear incapable of oxidizing sulfur compounds other than sulfides. They are photosynthetic and are capable of growing in anaerobic culture when illuminated. The green pigment differs from the green plant chlorophylls and from the bacteriochlorophyll of the purple bacteria, but has the characteristics of a chlorophyllous compound. These are grouped in the family *Chlorobacteriaceae*.

FAMILY I. THIORHODACEAE MOLISCH.

(Molisch, Die Purpurbakterien, Jena, 1907, 27; Subfamily *Chromatioideae* Buchanan, Jour. Bact., *3*, 1918, 464; *Rhodo-Thiobacteria* Bavendamm, Die farblosen und roten Schwefelbacterien, Pflanzenforschung, Heft 2, 1924, 102; *Rhodothiobacteria* Bavendamm, Ergeb. Biol., *13*, 1936, 49.)

Unicellular organisms, often developing as cell aggregates or families of variable size and shape. Single cells have the form of spheres, ovoids, short rods, vibrios, spirals, long rods or, occasionally, chains. They occur in nature in environments containing sulfides and require light for their development; infra-red irradiation of a wave-length extending to about 900 millimicrons is effective. They produce a pigment system composed of green bacteriochlorophyll, and yellow and red carotenoids. As a result they appear as pale purple, brownish to deep red cell masses. Single cells, unless they are of considerable size, usually appear to be unpigmented. These are anaerobic or microaerophilic organisms, with a photosynthetic metabolism in which carbon dioxide is reduced with the aid of special hydrogen donors without the liberation of molecular oxygen. Where these organisms are found in nature, hydrogen sulfide acts as a hydrogen donor, and sulfur, the first intermediate oxidation product, accumulates as sulfur droplets in the cells. Probably all members of the group can utilize a number of organic substances other than hydrogen sulfide as hydrogen donors for photosynthesis. Thus they are potentially mixotrophic.

Characterization of the genera in this group has since Winogradsky's studies (Beiträge zur Morphologie und Physiologie der Schwefelbacterien, Leipzig, 1888) been based upon the mode of development of the cell aggregates. Pure culture studies (Bavendamm, Die farblosen und roten Bakterien, I. Schwefelbakterien, Pflanzenforschung, Heft 2, 1924, 74 pp.; van Niel, Arch. f. Mikrobiol., *3*, 1931, 1–112; Manten, Antonie van Leeuwenhoek, *8*, 1942, 164 pp.) have since shown that not only the sequence of events in the formation of the aggregates but also the appearance and form of the latter even including the size and shape of the component cells are influenced to a considerable extent by environmental conditions. This obviously casts doubt upon the usefulness of the previously used diagnostic criteria for genera and species. On the other hand, the scope of pure culture studies has not yet attained sufficient breadth to warrant the use of a different approach. As a provisional measure, Winogradsky's genera are therefore maintained. Even the larger taxonomic units must be regarded as being of tentative value only.

Key to the genera of the family **Thiorhodaceae.**

I. Cells usually combined into aggregates.
  A. Cells grouped as regular sarcina packets.
    Genus I. *Thiosarcina*, p. 842.
  B. Cells not in sarcina packets.
    1. Aggregates in the form of a flat sheet.
      a. Cells in regular arrangement, with tetrads as the common structural unit.
        Genus II. *Thiopedia*, p. 843.
      aa. Cells in irregular aggregates.
        Genus III. *Thiocapsa*, p. 844.

2. Aggregates in the form of three-dimensional masses.
   a. Cells distinctly rod-shaped, and arranged in a net-like structure.
      Genus IV. *Thiodictyon*, p. 845.
   aa. Cells not so arranged.
      b. Cells in a common capsule, individuals rather scattered and loosely grouped.
         Genus V. *Thiothece*, p. 846.
      bb. Cells in rather dense clumps.
         c. Aggregates embedded in conspicuous common slime capsule.
            d. Aggregates small, compact, often several of them enclosed together in a common capsule.
               Genus VI. *Thiocystis*, p. 846.
            dd. Aggregates large and solid, later break up into small clusters.
               Genus VII. *Lamprocystis*, p. 847.
         cc. Common capsule lacking or very transient.
            d. Aggregates as a whole exhibit amoeboid movements.
               Genus VIII. *Amoebobacter*, p. 848.
            dd. Aggregates devoid of amoeboid movements.
               Genus IX. *Thiopolycoccus*, p. 850.

II. Cells usually occurring singly.
   A. Cells clearly spiral-shaped.
      Genus X. *Thiospirillum*, p. 850.
   B. Cells not spiral-shaped.
      1. Cells irregular, often swollen, distorted, or composed of long, crooked and bent rods to filaments.
         Genus XI. *Rhabdomonas*, p. 853.
      2. Cells regular, spherical to short rods or bean-shaped.
         a. Cells spherical, as a rule non-motile, and each one surrounded by a rather wide capsule.
            Genus XII. *Rhodothece*, p. 855.
         aa. Cells ellipsoidal, ovoid, short rods or vibrios, actively motile.
            Genus XIII. *Chromatium*, p. 856.

Genus I. Thiosarcina *Winogradsky.*

(Winogradsky, Zur Morphologie und Physiologie der Bacterien, I. Schwefelbacterien, Leipzig, 1888, 104; *Rhodosarcina* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 344; *Rhodothiosarcina* Ellis, Sulphur Bacteria, London and New York, 1932, 163.) From Greek *theion*, sulfur and Latin *sarcina*, bundle, packet.

Individual cells spherical, forming regular cubical packets of sarcina-shape, resulting from consecutive division in three perpendicular planes. Packets commonly containing 8 to 64 cells. Motility infrequent. Non-spore-forming. Contain bacteriochlorophyll and carotenoid pigments, hence, pigmented purplish to red. Capable of carrying out a photosynthetic metabolism in the presence of hydrogen sulfide, cells then store sulfur globules. Anaerobic.

The type species is *Thiosarcina rosea* (Schroeter) Winogradsky.

1. **Thiosarcina rosea** (Schroeter) Winogradsky. (*Sarcina rosea* Schroeter, Kryptog. Flora von Schlesien, *3*, 1, 1886, 154; *Sarcina sulphurata* Winogradsky, Bot. Ztg., *45*, 1887, 576; Winogradsky, Zur Morphologie und Physiologie

der Schwefelbacterien, Leipzig, 1888, 104; *Rhodothiosarcina rosea* Ellis, Sulphur Bacteria, London and New York, 1932, 163.) From Latin *roseus*, rose-colored.

Cells spherical, 2 to 3 microns in diameter, occurring in packets containing 8 to 64 cells. Infrequent motility. Color ranging from purplish-rose to nearly black.

Anaerobic.

Habitat: Mud and stagnant bodies of water containing hydrogen sulfide and exposed to light; sulfur springs.

Distribution: Probably ubiquitous. One of the less frequent among the purple sulfur bacteria.

Illustration: Issatchenko, Recherches sur les microbes de l'océan glacial arctique, Petrograd, 1914, Plate II, fig. 5.

Genus II. Thiopedia *Winogradsky.*

(Zur Morphologie und Physiologie der Bacterien, I. Schwefelbacterien, Leipzig, 1888, 85.) From Greek *theion* sulfur and *pedion*, plane.

Individual cells spherical to short rod-shaped, the latter shortly before cell division. Arranged in flat sheets with typical tetrads as the structural units. These arise from divisions of the cells in two perpendicular directions. Cell aggregates of various sizes, ranging from single tetrads to large sheets composed of thousands of cells. Motility infrequent. Non-spore-forming. Contain bacteriochlorophyll and carotenoid pigments. Capable of photosynthesis in the presence of hydrogen sulfide, and then storing sulfur globules. Anaerobic.

The type species is *Thiopedia rosea* Winogradsky.

1. **Thiopedia rosea** Winogradsky. (*Erythroconis littoralis* Oerstedt, Naturhist. Tidskrift, *3*, 1840–1841, 555; *Merismopedia littoralis* Rabenhorst, Flora Europaea Algarum, Leipzig, *2*, 1865, 57; Winogradsky, Zur Morphologie und Physiologie der Schwefelbacterien, Leipzig, 1888, 85; *Pediococcus roseus* Trevisan, I generi e le specie delle Batteriacee, Milan, 1889, 28; *Lampropedia rosea* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1049; *Planococcus roseus* Migula, in Engler and Prantl, Die natürlichen Pflanzenfamilien, *1*, 1a, 1895, 19.) From Latin *roseus*, rose-colored.

Size: 1 to 2 microns, often appearing as slightly elongated cocci regularly arranged in platelets. Color, pale red to nearly black, depending upon the amount of sulfur stored. Red color visible only with large cell masses, not in individuals.

According to Winogradsky, the cells are often embedded in a common slime capsule; the extensive studies of Utermöhl (Archiv f. Hydrobiol., Suppl. Vol. *5*, 1925, 251–276) make the regular occurrence of such capsules extremely doubtful. On the other hand, Utermöhl emphasizes as quite characteristic the common presence of a relatively large pseudovacuole, or aerosome, in the cells of this species encountered in plankton samples. Winogradsky does not mention this; nevertheless, it appears to be a regular and valuable distinguishing feature.

Anaerobic.

Habitat: Mud and stagnant bodies of fresh, brackish and salt water containing hydrogen sulfide and exposed to light; sulfur springs.

Distribution: Ubiquitous. Common, frequently giving rise to very extensive mass developments.

Illustrations: Warming, Videnskab. Meddel. naturhist. Forening, Kjöbenhavn, 1876, Plate VIII, fig. 2; Winogradsky, *loc. cit.*, Plate III, fig. 18; Pringsheim, Naturwissensch., *20*, 1932, 481, the last one a truly excellent photomicrograph.

Appendix: The following genus was formerly placed near *Thiopedia.* Winogradsky, Migula, E. F. Smith and others disregard this genus. A record is included here because of its historic interest.

Genus A. *Lampropedia* Schroeter.

(Schroeter, in Cohn, Kryptog. Flora v. Schlesien, *3*, 1, 1886, 151.) From Greek *lampros*, bright and *pedion*, plane.

Trevisan (I generi e le specie delle Batteriacee, 1889, 28) and DeToni and Trevisan (in Saccardo, Sylloge Fungorum, *8*, 1889, 1048) list as synonyms: *Erythroconis* Oersted, Naturhistorisk Tidsskrift, *2*, 1840, 555; in part, *Pediococcus* Lindner, Inaug. Diss., Berlin, 1887, 97; *Thiopedia* Winogradsky, Schwefelbacterien, Leipzig, 1888, 85.

Cells united into tetrads, forming flat, tubular masses, contain sulfur globules and bacteriochlorophyll and yellow and red carotenoids.

The type species is *Lampropedia hyalina* (Ehrenberg) Schroeter.

1. *Lampropedia hyalina* (Ehrenberg) Schroeter. (*Gonium hyalinum* Ehrenberg, Abhandl. d. Berl. Akad., 1830; *Merismopedia hyalina* Kützing, Species Algarum, 1849; *Sarcina hyalina* Winter, in Rabenhorst, Kryptogamen-Flora, 2 Aufl., *1*, 1884, 51; Schroeter, in Cohn, Kryptogram. Flora v. Schlesien, *3*, *1*, 1886, 151; *Pediococcus hyalinus* Trevisan, I generi e le specie delle Batteriacee, 1889, 28; *Micrococcus hyalinus* Migula, Syst. d. Bakt., *2*, 1900, 195.) From swamp water and decomposing materials from sugar refineries.

2. *Lampropedia reitenbachii* (Caspary) DeToni and Trevisan. (*Merismopedium reitenbachii* Caspary, Schriften d. physik. ökon. Gesellsch. zu Königsberg, *15*, 1874, 104; *Sarcina reitenbachii* Winter, in Rabenhorst, Kryptogamen-Flora, 2 Aufl., *1*, 1884, 50; *Pediococcus reichenbachii* (sic) Trevisan, I generi e le specie delle Batteriacee, 1889, 28; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1048.) Found on rotting water-plants.

3. *Lampropedia violacea* (Breb.) DeToni and Trevisan. (*Agmenellum violaceum* Breb., quoted from DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1049; *Merismopedia violacea* Kützing, Species Algarum, 1849, 472; *Pediococcus violaceus* Trevisan, I generi e le specie delle Batteriacee, 1889, 28; DeToni and Trevisan, *loc. cit.*, 1048.) From stagnant water. Common.

4. *Lampropedia ochracea* (Mettenheimer) DeToni and Trevisan. (*Merismopedia ochracea* Mettenheimer, Abhandl. d. Senkemberg. naturforsch. Gesellsch. in Frankf., *2*, 1856–58, 41; DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1049.) From the yellowish slime from a well at Frankfurt.

Genus III. **Thiocapsa** *Winogradsky.*

(Schwefelbacterien, Leipzig, 1888, 84.) From Greek *theion*, sulfur and Latin *capsa*, container, capsule.

Cells spherical, occurring in families of irregularly arranged individuals held together in a common slime capsule. The aggregates are spread out flat on the substrate. Motility not observed. As the colony grows, the capsule bursts, and the cells are spread apart. General morphology and development thus appears similar to that in the genus *Aphanocapsa* among the blue-green algae. Contain bacteriochlorophyll and carotenoid pigments; capable of photosynthesis in the presence of hydrogen sulfide. Under such conditions sulfur is stored in the form of globules in

the cells. This genus is so much like *Thiothece* that it is doubtful whether a distinction can be maintained.

The type species is *Thiocapsa roseopersicina* Winogradsky.

Key to the species of genus **Thiocapsa.**

I. Individual cells about 3 microns in diameter.
1. *Thiocapsa roseopersicina.*

II. Individual cells about 1.5 microns in diameter.
2. *Thiocapsa floridana.*

1. **Thiocapsa roseopersicina** Winogradsky. (Schwefelbacterien, Leipzig, 1888, 84.) From Latin *roseus*, rose-colored and *persicum*, peach; M.L., peach-colored.

Cells: Spherical, 2.5 to 3 microns in diameter, occurring in families of irregularly arranged individuals held together in a common slime capsule. Motility not observed. Usually a distinct rose-red. Stored sulfur droplets may attain a considerable size.

Habitat: Mud and stagnant bodies of water containing hydrogen sulfide and exposed to light; sulfur springs.

Illustration: Winogradsky, *loc. cit.*, Plate IV, fig. 15.

2. **Thiocapsa floridana** Uphof. (Uphof, Arch. f. Hydrobiol., *18*, 1927, 84; *Thiocapsa minima* Issatchenko, Borodin Jubilee Volume, p. 6, 1929?.) From the locality, Florida, where the organism was first found.

Cells: Spherical. About 1.5 microns in diameter. In groups of irregular colonies, each surrounded by a common capsule, several colonies being stuck together. Motility not observed.

Source: Palm Springs, Florida and Lake Sakskoje, near Eupatoria, Crimea.

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; sulfur springs. Probably ubiquitous.

Illustration: Uphof, *loc. cit.*, 83, fig. VI.

Genus IV. **Thiodictyon** *Winogradsky.*

(Winogradsky, Schwefelbacterien, Leipzig, 1888, 80; *Rhododictyon* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 334.) From Greek *theion*, sulfur and *dictyon*, net.

Cells rod-shaped, frequently with pointed ends, somewhat resembling spindles. Form aggregates in which the cells become arranged end to end in a net-like structure, somewhat reminiscent of the shape of the green alga *Hydrodictyon*. The shape is not constant; cells may also form more compact masses. Sometimes groups of cells separate from the main aggregate by active movements. Common gelatinous capsule not observed. Contain bacteriochlorophyll and carotenoid pigments; cells usually very faintly colored. Capable of photosynthesis in the presence of hydrogen sulfide; the cells then store sulfur as small globules.

The type species is *Thiodictyon elegans* Winogradsky.

1. **Thiodictyon elegans** Winogradsky. (Winogradsky, Schwefelbacterien, Leipzig, 1888, 80; *Thiodictyon minus* Issatchenko, Recherches sur les microbes de l'océan glacial arctique, Petrograd, 1914, 251.) From Latin *elegans*, tasteful, elegant.

Rods: 1.5 to 1.7 by 2.5 to 5 microns; or longer just prior to cell division. Usually contain a large pseudovacuole (aerosome), leaving a rather thin protoplasmic sheath along the cell wall.

Sulfur droplets: Generally quite small, and deposited exclusively in the thin protoplasmic layer.

Issatchenko (Études microbiologiques des Lacs de Boue, Leningrad, 1927, 113–114) recognizes a forma *minus* and a forma *magna*, differentiated mainly by the size of the individual rods.

Habitat: Mud and stagnant water, containing hydrogen sulfide, and exposed to light; sulfur springs.

Illustrations: Winogradsky, *loc. cit.*, Plate III, fig. 13–17.

Genus V. **Thiothece** *Winogradsky.*

(Winogradsky, Schwefelbacterien, Leipzig, 1888, 82; *Thiosphaera* Miyoshi, Jour. Coll. Sci., Imp. Univ. Tokyo, Japan, *10*, 1897, 170.) From Greek *theion*, sulfur and *theke*, container.

Purple sulfur bacteria which, in their growth characteristics, resemble the blue-green alga *Aphanothece*. Cells spherical to relatively long cylindrical-ellipsoidal, embedded in a gelatinous capsule of considerable dimensions. Following cell division the daughter cells continue to secrete mucus which causes the individual bacteria to remain clearly separated by an appreciable distance; the common capsule thus appears only loosely filled. The cells may become actively motile and separate themselves from the colony. Such swarmers closely resemble the cells of certain species of *Chromatium*. Contain bacteriochlorophyll and carotenoid pigments. Capable of photosynthesis in the presence of hydrogen sulfide, producing elementary sulfur as an intermediate oxidation product which is stored as sulfur globules inside the cells.

The type species is *Thiothece gelatinosa* Winogradsky.

1. **Thiothece gelatinosa** Winogradsky. (Winogradsky, Schwefelbacterien, Leipzig, 1888, 82; *Thiosphaera gelatinosa* Miyoshi, Jour. Coll. Sci., Imp. Univ. Tokyo, Japan, *10*, 1897, 170; *Lamprocystis gelatinosa* Migula, Syst. d. Bakt., *2*, 1900, 1044; *Chromatium sphaeroides* Hama, Jour. Sci. Hiroshima Univ., Ser. B, Div. 2, Bot., *1*, 1933, 158.) From Latin *gelatio*, freezing, indicating solidification or clumping.

Cells: 4 to 6 by 4 to 7 microns, spherical to cylindrical. Color of individual cells, faint, often grayish-violet, or even dirty yellowish. Sulfur globules usually deposited in outermost layers of protoplasm, and generally small.

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; sulfur springs.

Illustrations: Winogradsky, *loc. cit.*, Pl. III, fig. 9–12; Miyoshi, *loc. cit.*, Pl. XIV, fig. 25.

Genus VI. **Thiocystis** *Winogradsky.*

(Schwefelbacterien, Leipzig, 1888, 60.) From Greek *theion*, sulfur and *kystis*, sac, bladder.

Purple sulfur bacteria which form compact colonies, many of which may be loosely embedded in a common gelatinous capsule. Individual cells spherical to ovoid, often diplococcus-shaped. Colonies may emerge as more or less large units from out of the common capsule and break up afterwards, sometimes into single swarmers; or the aggregates may split up inside the original capsule, and release small motile units or single swarmers. In pure cultures frequently developing as single cells and diplococci. Produce bacteriochlorophyll and carotenoid pigments, coloring the cell masses purplish to red. Capable of photosynthesis in the presence of hydrogen sulfide, whereby elementary sulfur is formed as an intermediate oxidation product which is deposited as droplets inside the cells.

The type species is *Thiocystis violacea* Winogradsky.

Key to the species of genus **Thiocystis.**

I. Individual cells more than 2 microns in width.
1. *Thiocystis violacea.*

II. Individual cells about 1 micron or less in width.
2. *Thiocystis rufa.*

1. **Thiocystis violacea** Winogradsky. (Winogradsky, Schwefelbacterien, Leipzig, 1888, 65; *Planosarcina violacea* Migula, in Engler and Prantl, Die natürl. Pflanzenfamilien, *1*, 1a, 1895, 20.) From Latin *violaceus*, violet-colored.

Cells: About 2.5 to 5.5 microns in diameter, spherical to ovoid. Swarmers actively motile by means of polar flagella.

Colonies: Small, inside a common capsule, containing not over 30 cells. Several such colonies form loosely arranged aggregates, most characteristically composed of about 10 to 20 colonies in a single capsule. The result is a nearly spherical zoogloea. In small colonies, the cells appear as rather distinct tetrads; in larger colonies, the cells become somewhat compressed and the tetrad-like arrangement may be lost.

In pure cultures, the species often fails to produce the characteristic capsules; the organisms then occur as actively motile single cells or diplococci, with little or no slime formation. No pseudocapsules are formed.

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; sulfur springs.

Illustrations: Zopf, Zur Morphologie der Spaltpflanzen, Leipzig, 1882, Pl. V, fig. 12; Winogradsky, *loc. cit.*, Pl. II, Fig. 1–7.

2. **Thiocystis rufa** Winogradsky. (Schwefelbacterien, Leipzig, 1888, 65.) From Latin *rufus*, red.

Cells: Less than 1 micron in diameter. Color red, usually darker than in the type species. When the cells are stuffed with sulfur globules, the aggregates appear almost black.

The common gelatinous capsule usually contains a far greater number of closely packed individual colonies than is the case in *Thiocystis violacea.*

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; sulfur springs.

Illustration: Winogradsky, *loc. cit.*, Pl. II, fig. 8.

Genus VII. **Lamprocystis** *Schroeter.*

(In part, *Clathrocystis* Cohn, Beitr. Biol. Pfl., *1*, Heft 3, 1875, 156; in part, *Cohnia* Winter, in Rabenhorst, Kryptogamen-Flora, 2 Aufl., 1884, 48; Schroeter, Die Pilze Schlesiens, in Cohn, Kryptogamen-Flora von Schlesien, *3*, 1, 1886, 151; *Cenomesia?* de Toni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1039; *Lankasteron* Ellis, Sulphur Bacteria, London and New York, 1932, 135.) From Greek *lampros*, bright, shining, and *kystis*, sac or bladder.

Purple sulfur bacteria which form more or less large aggregates of cells enclosed in a common gelatinous capsule. Individual cells spherical to ovoid. Small aggregates closely resemble those of *Thiocystis*, even to the extent of the tetrad-like arrangement of cells in the small colonies. Behavior of the large aggregates during development appears to be different; the small individual cell groups or colonies do not emerge from the slime capsule until the initially relatively compact cell mass becomes broken up into smaller clusters, these eventually forming a somewhat net-

like structure. This behavior has been ascribed to a change in the mode of cell division which at first appears to take place in three perpendicular planes, and later presumably changes to a division in only two directions. Cells when free are motile by means of polar flagella. In pure culture also this type rarely, if ever, produces large aggregates with the development here mentioned as characteristic for the genus (Bavendamm, Die farblosen und roten Schwefelbakterien, Pflanzenforschung, Heft 2, 1924, 76). This, along with the other similarities, makes it doubtful whether future studies will result in the retention of the genera *Lamprocystis* and *Thiocystis* side by side. Produce bacteriochlorophyll and carotenoid pigments, coloring the cell masses purplish-pink to red. Capable of photosynthesis in the presence of hydrogen sulfide, storing elementary sulfur as globules inside the cells.

The type species is *Lamprocystis roseopersicina* (Kützing) Schroeter.

1. **Lamprocystis roseopersicina** (Kützing) Schroeter. (*Microloa rosca* Kützing, Linnaea, *8*, 1833, 371; *Cryptococcus roscus* Kützing, Phycologia generalis, Leipzig, 1843, 149; *Protococcus roseopersicinus* Kützing, Species Algarum, Leipzig, 1849, 196; *Palmella persicina* Cohn, Leonhard's Jarhb. f. Mineralog., 1864, 606; *Pleurococcus roseo-persicinus* Rabenhorst, Flora Eur. Algarum, Leipzig, *3*, 1868, 28; *Bacterium rubescens* Lankester, Quart. Rev. Micro. Sci., *13*, 1873, 408; not *Bacterium rubescens* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 115; *Clathrocystis roseopersicina* Cohn, Beitr. Biol. Pfl., *1*, Heft 3, 1875, 157; *Cohnia roseo-persicina* Winter, in Rabenhorst, Kryptogamen Flora, 2 Aufl., *1*, 1884, 48; Schroeter, in Cohn, Kryptogamen-Flora von Schlesien, *3*, 1, 1886, 151; *Planosarcina roseo-persicina* Migula, in Engler and Prantl, Die natürlichen Pflanzenfam., *1*, 1a, 1895, 20; *Lankasteron rubescens* Ellis, Sulphur Bacteria, London and New York, 1932, 135.) From Latin *roseus*, rose-colored and *persicum*, peach; M.L., peach-colored.

In all probability, *Thioderma rubrum* Miyoshi (Jour. Coll. Sci., Imp. Univ. Tokyo, Japan, *10*, 1897, 170) is identical with this species.

Cells: Spherical to ovoid, 2 to 2.5 microns in diameter, up to 5 microns long before cell division. Motile. Polar flagellate.

Winogradsky (*loc. cit.*) reports that the cells frequently contain pseudovacuoles.

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; sulfur springs.

Illustrations: Warming, Videnskab. Meddel. naturhistor. Foren., Kjöbenhavn, 1876, Pl. VIII, fig. 3 g; Zopf, Z. Morphol. d. Spaltpflanzen, Leipzig, 1882, Pl. V, fig. 8, 13; Winogradsky, Schwefelbacterien, Leipzig, 1888, Pl. II, fig. 9–15; Bavendamm, Die farblosen und roten Schwefelbakterien, Jena, 1924, Pl. II, fig. 3.

Genus VIII. Amoebobacter *Winogradsky.*

(Winogradsky, Schwefelbacterien, Leipzig, 1888, 71; *Amoebomonas* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 334.) From *amoeba*, one of the protozoa characterized by a constantly changing shape, and Greek *baktron*, rod.

Purple sulfur bacteria, usually occurring in aggregates composed of many individuals without a characteristic common capsule. Slime formation can, nevertheless, be observed with very small colonies. With growth of the individual cells, the capsule bursts and the cell mass slowly moves out while the bacteria remain united. The colonies change their shape during growth and in response to environmental influences; the individual cells appear motile and cause the movements of the entire

colony. Winogradsky ascribes the coherence of the cell masses to the existence of interconnecting protoplasmic filaments between cells, but these have never been observed, and their occurrence is extremely doubtful. It is much more probable that the bacteria are held together by mucus, though not so much of the latter is produced as to form a clearly discernible capsule.

Produce bacteriochlorophyll and carotenoid pigments. Capable of photosynthesis in the presence of hydrogen sulfide, and then store sulfur as droplets inside the cells.

The type species is *Amoebobacter roseus* Winogradsky.

Since the characterization of the genera *Amoebobacter*, *Lamprocystis*, *Thiocystis*, *Thiocapsa* and *Thiothece* is based upon the arrangement of individual bacteria in a common capsule, which, from Winogradsky's descriptions of *Amoebobacter* and from pure culture studies with *Thiocystis* and *Lamprocystis*, has been shown to vary considerably, depending upon developmental stages and environmental conditions, it is quite possible that future investigations will show the desirability of restricting the number of genera.

Key to the species of genus **Amoebobacter.**

I. Cells spherical to ovoid, about 2.5 to 3.5 microns in diameter and up to 6 microns in length prior to cell division.
   1. *Amoebobacter roseus.*

II. Cells distinctly rod-shaped, about 1.5 to 2 microns in width by 2 to 4 microns in length.
   2. *Amoebobacter bacillosus.*

III. Cells spherical, quite small, about 0.5 to 1 micron in diameter.
   3. *Amoebobacter granula.*

1. **Amoebobacter roseus** Winogradsky. (Schwefelbacterien, Leipzig, 1888, 77.) From Latin *roseus*, rose.

Cells spherical to ovoid, 2.5 to 3.5 microns in width and up to 6 microns in length. Motile. Often contain pseudovacuoles. Cell-aggregates often form transitory hollow spheres or sacks, with the bacteria occupying the periphery as a shallow layer. These are reminiscent of stages in the development of *Lamprocystis*.

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; sulfur springs.

Illustrations: Winogradsky, *loc. cit.*, Pl. III, fig. 1–6.

2. **Amoebobacter bacillosus** Winogradsky. (Winogradsky, Schwefelbacterien, Leipzig, 1888, 78; *Thioderma roseum* Miyoshi, Jour. Coll. Sci., Imp. Univ. Tokyo, Japan, *10*, 1897, 158.) From Latin *bacillus*, resembling a rod.

Cells rod-shaped, about 1.5 to 2 microns by 2 to 4 microns. Cells contain pseudovacuoles (aerosomes). Sulfur globules deposited exclusively in peripheral protoplasmic layer, usually quite small.

Habitat: Mud and stagnant water, containing hydrogen sulfide and exposed to light; sulfur springs.

Illustrations: Zopf, Z. Morphol. d. Spaltpfl., Leipzig, 1882, Pl. V, fig. 26–27; Winogradsky, *loc. cit.*, Pl. III, fig. 7.

Miyoshi's incomplete description of *Thioderma roseum* (*loc. cit.*), type species of genus *Thioderma*, is sufficient to make practically certain that it is identical with *Amoebobacter bacillosus*. The description of *Thiodictyon elegans* Winogradsky (*loc. cit.*) suggests that it cannot be distinguished from this species.

3. **Amoebobacter granula** Winogradsky. (Schwefelbacterien, Leipzig, 1888, 78.) From Latin *granulus*, a granule.

Cells: Spherical, small, about 0.5 to 1 micron in diameter. Faint pigmentation; the sulfur inclusions give the cell masses a black appearance. Aggregates are apt to consist of closely-knit masses which are difficult to separate.

When sulfur is stored, a single droplet usually fills most of the cell. Because of the high refractive index of this globule, it becomes difficult if not impossible to make accurate observations of the cell shape.

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; sulfur springs.

Illustration: Winogradsky, *loc. cit.*, Pl. III, fig. 8.

Genus IX. **Thiopolycoccus** *Winogradsky.*

(Winogradsky, Schwefelbacterien, Leipzig, 1888, 79; *Rhodopolycoccus* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 334.) From Greek *theion*, sulfur; *polys*, many; and *kokkos*, granule or small cell.

Purple sulfur bacteria which form dense aggregates of rather solid construction and irregular shape. The colonies appear, in contrast with *Amoebobacter*, non-motile and do not tend to form hollow zoogloeal structures by which they are differentiated from *Lamprocystis*. Cell masses held together by mucus which does not, however, appear as a regular capsule. Large clumps may fissure with the formation of irregular shreds and lobes which continue to break up into smaller groups of cells. Individual bacteria spherical, motility not observed. Contain bacteriochlorophyll and carotenoid pigments, so that the aggregates, in accord with the dense packing with individual cells, appear distinctly red. Capable of photosynthesis in the presence of hydrogen sulfide, when the cells store elementary sulfur as droplets inside the cells.

The type species is *Thiopolycoccus ruber* Winogradsky.

1. **Thiopolycoccus ruber** Winogradsky. (Winogradsky, Schwefelbacterien, Leipzig, 1888, 79; *Micrococcus ruber* Migula, in Engler and Prantl, Die natürlichen Pflanzenfamilien, *1*, 1a, 1895, 18.) From Latin *ruber*, red.

Cells: Spherical, about 1.2 microns in diameter. No motility observed.

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; sulfur springs.

Illustrations: Winogradsky, *loc. cit.*, Pl. IV, fig. 16–18; Issatchenko, Recherches sur les microbes de l'océan glacial arctique, Petrograd, 1914, Pl. II, fig. 7.

Genus X. **Thiospirillum** *Winogradsky.*

(*Ophidomonas* Ehrenberg, Die Infusionstierchen, Leipzig, 1838, 43; Winogradsky, Schwefelbacterien, Leipzig, 1888, 104; *Thiorhodospirillum* Fuhrmann, Vorlesungen ü. techn. Mykologie, Jena, 1913, 325; *Rhodothiospirillum* Bavendamm, Schwefelbakterien, Jena, 1924, 115.) From Greek *theion*, sulfur, and diminutive of *spira*, screw.

Purple sulfur bacteria, occurring singly, as spirally wound cells, motile by means of polar flagella. Contain bacteriochlorophyll and carotenoid pigments, coloring the cells brownish- to purplish-red. Capable of photosynthesis in the presence of hydrogen sulfide, during which they produce and store, as an intermediate oxidation product, elementary sulfur in the form of droplets inside the cells.

The differentiation of species in this group has been based exclusively on observa-

tions with material from natural collections and from laboratory mass cultures. The criteria used are the size and shape of the spirals, and the color of the organisms. Not a single representative has so far been obtained and studied in pure culture, so that no information is available concerning the constancy or variability of these characteristics. It is, however, likely that such properties may be greatly influenced by environmental factors. Hence, the following key and descriptions of species are apt to be modified when more extensive studies have been made. The published descriptions of some species make it seem probable that they should not even be incorporated in *Thiospirillum*.

The type species is *Thiospirillum jenense* (Ehrenberg) Winogradsky.

Key to the species of genus **Thiospirillum.**

I. Width of cells 2.5 microns or more.
   1. Color of cells, especially in masses, yellowish-brown to orange-brown.
      1. *Thiospirillum jenense.*
   2. Color of cells deep red or violet.
      a. Cells long, typical spirals; clearly red.
         2. *Thiospirillum sanguineum.*
      aa. Cells short, slightly curved, vibrio-shaped; color purple to violet-red.
         3. *Thiospirillum violaceum.*

II. Width of cells less than 2.5 microns.
   1. Width of cells 1.5 to 2.5 microns.
      4. *Thiospirillum rosenbergii.*
   2. Width of cells about 1 micron.
      5. *Thiospirillum rufum.*

1. **Thiospirillum jenense** (Ehrenberg) Winogradsky. (*Ophidomonas jenensis* Ehrenberg, Die Infusionstierchen, Leipzig, 1838, 44; *Spirillum jenense* Trevisan, Batter. ital., 1879, 26; Winogradsky, Schwefelbacterien, Leipzig, 1888, 104; *Rhodothiospirillum jenense* Ellis, Sulphur Bacteria, London and New York, 1932, 161; *Thiospirillum crassum* Hama, Jour. Sci. Hiroshima Univ., Ser. B, Div. 2, Bot., *1*, 1933, 157.) Named for the city of Jena, Germany, where Ehrenberg discovered this organism.

Cells: Cylindrical, sometimes pointed at ends, 2.5 to 4 microns long, coiled as spirals. Generally 30 to 40 microns in length but may be as long as 100 microns. Shape of individual coils varies, complete turns measuring about 15 to 40 microns in length, and from ½ to 1/10 of the width in height. Polar flagellate. Tufted at both ends. Olive-brown, sepia-brown and reddish-brown.

This coloring appears to be the only recognizable difference from *Thiospirillum sanguineum*. *Thiospirillum crassum* Hama (*loc. cit.*) reported to be 3.7 to 4 by 12 to 40 microns and yellowish-brown in color, thus becomes indistinguishable from *Thiospirillum jenense*; the 80 microns long *Thiospirillum jenense* forma *maxima* Szafer (Bull. Acad. Sci. Cracovie, Sér. B, 1910, 162) does not at present justify recognition as a special taxonomic entity.

It is even doubtful whether the observed color difference between *Thiospirillum jenense* and *Thiospirillum sanguineum* constitutes a valid criterion for their maintenance as two distinct species (Buder, Jahrb. wiss. Bot., *56*, 1915, 534; Bavendamm, Die farblosen und roten Schwefelbakterien, Pflanzenforschung, Heft 2, 1924, 131).

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; more rarely in sulfur springs.

Illustrations: Zettnow, Ztschr. f. Hyg., *24*, 1897, Pl. II, fig. 49-52; Buder, *loc. cit.*, fig. 1; Szafer, *loc. cit.*, Pl. IV, fig. 4; Hama, *loc. cit.*, Pl. 18, fig. 1, 8a; Pl. 19, fig. 1.

2. **Thiospirillum sanguineum** (Ehrenberg) Winogradsky. (*Ophidomonas sanguinea* Ehrenberg, Verhandl. Akad. Wiss. Berlin, 1840, 201; *Spirillum sanguineum* Cohn, Beitr. Biol. Pfl., *1*, Heft 3, 1875, 169; Winogradsky, Schwefelbacterien, Leipzig, 1888, 104.) From Latin *sanguineus*, blood-colored, red.

Cells: Cylindrical, sometimes attenuated at ends, spirally coiled; 2.5 to 4.0 microns in width, commonly about 40 microns long with a range of from 10 to 100 microns. Size and shape of coils variable, complete turns measuring from 15 to 40 microns in length and from ⅓ to 1/10 of the length in width. Polar flagellate, usually tufted at both ends. Individual cells rose-red with a grayish hue, groups of cells deep red. Sulfur droplets numerous under appropriate conditions.

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; rarely in sulfur springs.

Illustrations: Cohn, *loc. cit.*, Pl. VI, fig. 15; Warming, Vidensk. Meddel, naturhist. Foren., Kjöbenhavn, 1876, Pl. VII, fig. 8; Buder, Jahrb. wiss. Bot., *56*, 1915, 534, fig. 2.

3. **Thiospirillum violaceum** (Warming) Winogradsky. (*Spirillum violaceum* Warming, Vidensk. Meddel. naturhist. Foren., Kjöbenhavn, 1876, 395; Winogradsky, Schwefelbacterien, Leipzig, 1888, 104.) From Latin *violaceus*, violet-colored.

Cells: Short and fat, 3 to 4 by 8 to 10 microns, ends smoothly rounded. Slightly curved, bean- or vibrio-shaped. Only rarely are they twisted suggesting a spirillum. Polarly flagellated.

The shape of cell seems to fit the genus *Chromatium* rather than *Thiospirillum* and Warming (*loc. cit.*) emphasizes the resemblance to *Chromatium okenii*.

Color bluish-violet; this color may be related to a scarcity of sulfur droplets in the cells.

Habitat: Mud and stagnant water.

Illustration: Warming, *loc. cit.*, Pl. VII, fig. 3.

4. **Thiospirillum rosenbergii** (Warming) Winogradsky. (*Spirillum rosenbergii* Warming, Vidensk. Meddel. naturhist. Foren., Kjöbenhavn, 1876, 346; Winogradsky, Schwefelbacterien, Leipzig, 1888, 104.) Named for the Danish algologist, Rosenberg.

Cells: 1.5 to 2.5 by 4 to 12 microns; coiled, with turns of about 6 to 7.5 microns in length and variable width up to 3 or 4 microns. Color very dark, due to numerous sulfur globules. Color of protoplasm not recorded.

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light.

Distribution: Probably ubiquitous, but less frequently recorded as the organism is not as spectacular as the large *Thiospirillum jenense* and *Thiospirillum sanguineum*.

Illustration: Warming, *loc. cit.*, Pl. X, fig. 12.

5. **Thiospirillum rufum** (Perty) Migula. (*Spirillum rufum* Perty, Bern, 1852, 179; Migula, Syst. d. Bakt. *2*, 1900, 1050.) From Latin *rufus*, red, reddish.

General characteristics presumably those of the genus, although it does not appear either from Perty's description, or from those of Migula (*loc. cit.*), Bavendamm (Die farblosen und roten Schwefelbakterien Jena, 1924, 132) and Huber-Pestalozzi (Die Binnengewässer, *16*, Heft 1, Das Phytoplankton des Süsswassers, Stuttgart, 1938, 304) that the cells ever contain sulfur globules. Only the red color is emphasized. Consequently, it is quite possible that this

organism belongs in the genus *Rhodospirillum*.

Cells: 1.0 by 8 to 18 microns; coiled to occupy $1\frac{1}{2}$ to 4 turns, the latter commonly 4 microns wide by 4 microns long. These dimensions agree with those of *Rhodospirillum rubrum* (Esmarch) Molisch and the identity of the two organisms is probable.

Habitat: Found in red slime spots on the side of a well. Mud and stagnant bodies of water.

Illustration: Migula, Syst. d. Bakt., *1*, 1897, Pl. III, fig. 7.

Appendix: Three species have been placed in the genus *Thiospirillum* without convincing evidence that they conform to the generic diagnosis.

Thiospirillum agilis Kolkwitz. (Kolkwitz, Kryptogamenflora d. Mark Brandenburg, *5*, Pilze, 1909, 162; *Thiospira agilis* Bavendamm, Die farblosen und roten Schwefelbakterien, Pflanzenforschung, Heft 2, 1924, 116.) This is not known to have been a purple bacterium and hence may represent a member of the genus *Thiospira*.

Thiospirillum agilis var. *polonica* Strzeszewski. (Bull. Acad. Sci., Cracovie, Sér. B, 1913, 322.) This also may belong in the genus *Thiospira*.

Thiospirillum pistiense Czurda. (Cent. f. Bakt., II Abt., *92*, 1935, 409.) Not described as pigmented and does not contain sulfur globules. Reported to be a probable agent in the production of hydrogen sulfide from sulfates or sulfur. It may therefore be the spirillar form of *Vibrio desulfuricans* Beijerinck or, being thermophilic, of *Vibrio thermodesulfuricans* Elion.

Thiospirillum winogradskii Omeliansky. (Cent. f. Bakt., II Abt., *14*, 1905, 764.) This is colorless and is included in *Thiospira*.

Genus XI. Rhabdomonas *Cohn*

(Cohn, Beitr. Biol. Pfl., *1*, Heft 3, 1875, 167; *Mantegazzaea* Trevisan, R. Inst. Lombardo de Sci. e Lett., IV, Ser. 2, *12*, 1879, 137; *Rhabdochromatium* Winogradsky, Schwefelbacterien, Leipzig, 1888, 100; in part, *Rhodocapsa* Molisch, Die Purpurbakterien, Jena, 1907, 17.) From Greek *rhabdos*, a rod, and *monas*, a unit (cell).

Purple sulfur bacteria, as a rule occurring singly, in the form of rather irregular, long rods to filaments, exhibiting more or less pronounced swellings, or club and spindle shapes. Filamentous structures sometimes with constrictions giving the filament the appearance of a string of beads. These may be surrounded by a relatively inconspicuous slime capsule which can be rendered visible by India ink. The less distorted cell types are frequently motile, flagella polar. Produce bacteriochlorophyll and carotenoid pigments, coloring the cells pinkish- to purplish-red. Capable of photosynthesis in the presence of hydrogen sulfide and then storing sulfur globules as an intermediate oxidation product inside the cells.

The status of this genus is doubtful. Winogradsky (*loc. cit.*) recognized the similarity of its members to species of *Chromatium* and the occurrence of many intermediate forms which make a sharp distinction between the two genera impossible. He preferred the designation of *Rhabdochromatium* as a sub-genus. Warming (Videnskab. Meddel. naturhist. Foren., Kjöbenhavn, 1876, 320 ff.), Nadson (Bull. Jard. Impér. Bot. St. Pétersb., *3*, 1903, 116), van Niel (Arch. f. Mikrobiol., *3*, 1931, 61), and Ellis (Sulphur Bacteria, London and New York, 1932, 151) considered the species of *Rhabdochromatium* as abnormal growth forms (involution forms) of corresponding species of *Chromatium*, while Lauterborn (Verhandl. naturhistor.-medizin. Vereins, Heidelberg, N.F., *13*, 1915, 424), Buder (Jahrb. wiss. Bot., *58* 1919, 534) and Baven-

damm (Die farblosen und roten Schwefelbakterien, Pflanzenforschung, Heft 2, 1924, 129) favor generic rank.

The type species is *Rhabdomonas roseus* Cohn.

Key to the species of genus **Rhabdomonas.**

I. Cells not containing calcium carbonate inclusions in addition to sulfur globules.
 a. Cells more than 3 microns in width.
  1. *Rhabdomonas rosea.*
 aa. Cells less than 3 microns in width.
  2. *Rhabdomonas gracilis.*

II. Cells containing calcium carbonate inclusions in addition to sulfur globules.
  3. *Rhabdomonas linsbaueri.*

1. **Rhabdomonas rosea** Cohn. (Cohn, Beitr. Biol. Pfl., **1**, Heft 3, 1875, 167; *Beggiatoa roseo-persicina* Zopf, Z. Morphol. d. Spaltpflanzen, Leipzig, 1882, 30; *Rhabdochromatium roseum* Winogradsky, Schwefelbacterien, Leipzig, 1888, 100; *Rhabdochromatium fusiforme* Winogradsky, *ibid.*, 102; *Pseudomonas rosea* Migula, in Engler and Prantl, Die natürlichen Pflanzenfam., *1*, 1a, 1895, 30.) From Latin *roseus*, rose-colored.

Cells: Uneven in width and length, often swollen to spindle-shaped, sometimes tending towards filamentous growth. The greatest width of a spindle-shaped or fusiform cell may be close to 10 microns; in the more filamentous structures it is usually around 5 microns. The length varies between 10 and 30 microns for single cells; filamentous forms, frequently showing bulges and constrictions suggestive of compound structures in which cell division has been incomplete, may attain considerably greater lengths, up to 100 microns. The ends of spindle-shaped cells often taper to very fine points or attenuated fibers; also filaments are generally thinner toward the extremities. Single individuals and short filaments are motile by means of polar flagella, long filaments rarely motile. The ends of a filament may become pinched off and swim away.

Color rose-red; cells are usually filled with sulfur globules.

There is no good reason for maintaining *Rhabdomonas fusiformis* (*Rhabdochromatium fusiforme* Winogradsky) as a separate species; the variations in size and shape bring this form well within the range of *Rhabdomonas rosea*. Present indications strongly suggest that the latter species should be regarded as a peculiar developmental form of *Chromatium okenii*.

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; sulfur springs.

Illustrations: Cohn, *loc. cit.*, Pl. VI, fig. 14; Warming, Vidensk. Meddel. naturhistor. Foren., Kjöbenhavn, 1876, Pl. VII, fig. 1c-e; Zopf, *loc. cit.*, Pl. V, fig. 2b; Winogradsky, *loc. cit.*, Pl. IV, fig. 9-11, 13-14.

2. **Rhabdomonas gracilis** (Warming) Migula. (*Monas gracilis* Warming, Vidensk. Meddel. naturhist. Foren., Kjöbenhavn, 1876, 331; *Rhabdochromatium minus* Winogradsky, Schwefelbacterien, Leipzig, 1888, 102; *Rhabdochromatium gracile* Migula, Syst. d. Bakt., *2*, 1900, 1049; *Rhodocapsa suspensa* Molisch, Die Purpurbakterien, Jena, 1907, 17; *Rhabdomonas minor* Bergey et al., Manual, 3rd ed., 1930, 532.) From Latin *gracilis*, slender.

Cells: Much smaller than those of *Rhabdomonas rosea*, and with less tendency to form fusiform cells. Usually filamentous, more or less cylindrical, often with constrictions, but found up

to 60 microns in length. Shorter filaments motile. Polar flagellate. Slime formation may occur under special conditions. Rose-red. Sulfur globules. Probably an abnormal growth form of *Chromatium virosum*.

Habitat: Mud and stagnant water containing hydrogen sulfide and exposed to light; sulfur springs.

Illustrations: Warming, *loc. cit.*, Pl. VII, fig. 5; Winogradsky, *loc. cit.*, Pl. IV, fig. 12; Molisch, *loc. cit.*, Pl. II, fig. 11–12.

3. **Rhabdomonas linsbaueri** (Gicklhorn) *comb. nov.* (*Rhabdochromatium linsbaueri* Girklhorn, Ber. d. deut. bot. Ges., *39*, 1921, 312.) Named for the botanist, K. Linsbauer.

Cells: Resemble *Rhabdomonas rosea*, irregular, rod-shaped, 3 to 5 microns wide, up to 30 microns in length.

The characteristic feature of the species, and the chief means of differentiation, is the occurrence of calcium carbonate inclusions in addition to the sulfur globules in the cells. Whether this is strictly an environmentally conditioned characteristic, due to the photosynthetic development of the bacteria in a medium rich in calcium ions, so that calcium carbonate is precipitated as the alkalinity increases, has not yet been established, but seems possible. In that case the identity of this species with *Rhabdomonas rosea* would become evident.

Source: From a pond near Graz, Austria.

Habitat: Fresh water.

Genus XII. Rhodothece *Molisch.*

(Die Purpurbakterien, Jena, 1907, 19.) From Greek *rhodon*, rose and *theke*, container, capsule.

Purple sulfur bacteria, occurring singly, not aggregated in families. Cells spherical, each surrounded by a rather wide capsule which is, however, rarely visible without special staining. Motility not observed. Contain bacteriochlorophyll and carotenoid pigments, coloring the cells reddish. Capable of photosynthesis in the presence of hydrogen sulfide; the cells then store sulfur globules, arising as an intermediate oxidation product of the sulfide.

In view of the experiences of Bavendamm and others that a number of representatives of the purple sulfur bacteria, characterized by typical colonial aggregates when found in nature, may develop as single cells in pure culture, it is quite conceivable that the genus *Rhodothece* is synonymous with some other genus, e.g., *Lamprocystis*, and that the two genera represent different growth forms induced by environmental conditions.

The type species is *Rhodothece pendens* Molisch.

1. **Rhodothece pendens** Molisch. (Die Purpurbakterien, Jena, 1907, 19.) From Latin *pendeo*, to be suspended.

Cells: Spherical, frequently occurring as diplococci, occasionally as very short chains or clumps of 3 to 5 individuals. 1.8 to 2.5 microns in diameter. Produce rather abundant slime. Cells embedded in individual capsules which are rarely visible without staining (India ink). Characteristic is the regular occurrence of pseudovacuoles (aerosomes) which are supposed to keep the cells suspended in liquid media. Refractive phenomena due to the pseudovacuoles and to the sulfur globules distort the cell shape under ordinary illumination so that bacteria appear as polygons rather than round cells. Usually 2 aerosomes and 2 sulfur globules per cell. Color not observable in individual bacteria. Cell groups are rose-red. Motility not observed.

Habitat: Mud and stagnant water con-

taining hydrogen sulfide and exposed to light. Not reported from sulfur springs.

Illustrations: Molisch, Die Purpurbakterien, Jena, 1907, Pl. II, fig. 13-14.

Genus XIII. **Chromatium** *Perty.*

(Perty, Zur Kenntniss kleinster Lebensformen, Bern, 1852, 174; *Rhodomonas* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 334.) From Greek *chroma*, color.

Cells occur singly, more or less ovoid, bean- or vibrio-shaped, or short rods. The last-mentioned are often thick-cylindrical with rounded ends. Motile by means of polar flagella. Contain bacteriochlorophyll and carotenoid pigments, coloring the cells various shades of red. Capable of photosynthesis in the presence of hydrogen sulfide and storing elementary sulfur as an incomplete oxidation product in the form of globules inside the cells.

At present, the genus contains 11 described species and one variety. In addition, two more purple sulfur bacteria, *Pseudomonas molischii* Bersa (Planta, *2*, 1926, 375) and *Thiospirillum coccineum* Hama (Jour. Sci. Hiroshima Univ., Ser. B, Div. 2, Bot., *1*, 1933, 158), have been incorporated here as species of *Chromatium* because the descriptions and illustrations furnished by the original authors leave no doubt as to their taxonomic affiliations.

Differentiation of species has, in the past, been based almost entirely upon size and shape of individual cells, often with complete disregard for the variability of these criteria. The unsatisfactory and arbitrary nature of such a classification has occasionally been pointed out, and with much justification. Winogradsky (Schwefelbacterien, Leipzig, 1888, 98) mentions the many transitional stages that can be observed between *Chromatium okenii* and *Chromatium weissei*; Strzeszewski (Bullet. Acad. Sci., Cracovie, Sér. B, 1913, 321) holds that it is impossible to distinguish, on the basis of sizes or otherwise, between *Chromatium weissei* and *Chromatium minus*. Such contentions, derived from observations on material from natural collections or crude cultures, have been greatly strengthened by studies with pure cultures of species of *Chromatium*. Thus van Niel (Arch. f. Mikrobiol., *3*, 1931, 59) reported variations in width from 1 to 4 microns, and in length from 2 to 10 microns or even up to 50 microns; Manten (Antonie van Leeuwenhoek, *8*, 1942, 164 ff.) found size differences of 1 to 14 microns with a pure culture of an organism that he identified as *Chromatium okenii*. Often the differences in size of a pure culture can be related to special environmental conditions. On account of such results a designation of species on the basis of size relations alone is manifestly unsatisfactory. Moreover, the available data do not suggest that differences in shape, color or arrangement of sulfur globules can be used more effectively. Lack of adequate experimental results with a sufficiently large number and variety of pure cultures prevents a more rational classification at present.

The previously proposed species have been listed below with their respective characteristics and arranged as far as possible in the order of decreasing width.

Two *Chromatium* species have been described as containing inclusions of calcium carbonate in addition to sulfur globules. As in the case of *Rhabdomonas linsbaueri*, it is not known whether this feature may be a direct consequence of the calcium ion content and pH of the environment, and thus fail to have taxonomic significance.

The type species is *Chromatium okenii* Perty.

1. **Chromatium gobii** Issatchenko. (Recherches sur les microbes de l'océan glacial arctique, Petrograd, 1914, 253.)

Named for Prof. X. Gobi.

Cells: 10 microns by 20 to 25 microns.

Source: From sea water of Arctic Ocean.

Habitat: Presumably ubiquitous in the colder portions of the Ocean at least.

Illustration: Issatchenko, *loc. cit.*, Pl. II, fig. 12.

2. **Chromatium warmingii** (Cohn) Migula. (*Monas warmingii* Cohn, Beitr. Biol. Pfl., *1*, Heft 3, 1875, 167; Migula, Syst. d. Bakt., *2*, 1900, 1048.) Named for the Danish botanist, Eugene Warming.

Cells: 8 by 15 to 20 microns, also smaller (Cohn).

Illustration: Cohn, *loc. cit.*, Pl. VI, fig. 11.

2b. *Chromatium warmingii* forma *minus* Bavendamm. (Die farblosen und roten Schwefelbakterien, Pflanzenforschung, Heft 2, 1924, 127.) Named for the Danish botanist, Eugene Warming.

Cells: 4 by 6 to 10 microns.

Illustrations: Bavendamm, *loc. cit.*, 91, fig. 7, and Pl. II, fig. 12, a-b.

3. **Chromatium linsbaueri** Gicklhorn. (Ber. d. deut. botan. Ges., *39*, 1921, 312.) Named for the Austrian botanist, K. Linsbauer.

Cells: 6 by up to 15 microns (Gicklhorn); 6 to 8 microns in width (Ellis, Sulphur Bacteria, London and New York, 1932, 147). Special characteristic is the occurrence of calcium carbonate inclusions. Otherwise resembles *Chromatium okenii*.

Source: From a pool in the Stiftingtal, near Graz, Austria.

Habitat: Fresh water.

Illustrations: Gicklhorn, *loc. cit.*, 314, fig. 1; Ellis, *loc. cit.*, 148, fig. 31.

4. **Chromatium okenii** (Ehrenberg) Perty. (*Monas okenii* Ehrenberg, Infusionsthierchen, Leipzig, 1838; Perty, Zur Kenntniss kleinster Lebensformen, Bern, 1852, 174; *Bacillus okenii* Trevisan, I generi e le specie delle Batteriacee, 1889, 18; *Bacterium okenii* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1027; *Pseudomonas okenii* Migula, in Engler and Prantl, Die natürlichen Pflanzenfamilien, *1*, 1a, 1895, 30.) Named for the German naturalist, L. Oken. This is the type species of genus *Chromatium*.

Cells: 5.6 to 6.3 by 7.5 to 15 microns (Cohn); minimum width 4.5 microns (Issatchenko, Borodin Jubilee Vol., 1929?, 8); with many transitions to *Chromatium weissei* (Winogradsky, Schwefelbacterien, Leipzig, 1888, 92). Also: 3.5 by 8 to 12 microns and varying in size from 1 to 15 microns (Manten, Antonie van Leeuwenhoek, *8*, 1942, 164).

Illustrations: Cohn, Beitr. Biol. Pfl., *1*, Heft 3, 1875, Pl. VI, fig. 12; Winogradsky, *loc. cit.*, Pl. IV, fig. 3-4; Issatchenko, Recherches sur les microbes de l'océan glacial arctique, Petrograd, 1914, Pl. II, fig. 9.

5. **Chromatium weissei** Perty. (Perty, Zur Kenntniss kleinster Lebensformen, Bern, 1852, 174; *Bacillus weissii* Trevisan, I generi e le specie delle Batteriacee, 1889, 18; *Bacterium weissii* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1027.) Named for the zoologist, J. F. Weisse, consequently the more common spellings, *Chromatium weissii* or *C. weisii* are in error.

Cells: 4.2 by 5.7 to 11.5 microns (Perty); also 3 to 4 by 7 to 9 microns (Issatchenko, Borodin Jubilee Volume, 1929?, 8); transitions to *Chromatium okenii* (Winogradsky, Schwefelbacterien, Leipzig, 1888, 92); transitions to *Chromatium minus* (Strzeszewski, Bull. Acad. Sci., Cracovie, Sér. B. 1913, 321).

Illustrations: Winogradsky, *loc. cit.*, Pl. IV, fig. 1-2; Miyoshi, Jour. Coll. Sci., Imp. Univ. Tokyo, Japan, *10*, 1897, Pl. XIV, fig. 15.

6. **Chromatium cuculliferum** Gicklhorn. (Cent. f. Bakt., II Abt., *50*, 1920, 419.) From Latin *cucullus*, cap or hood and *fero*, to bear.

Cells: 4 by 6 to 8 microns (Gicklhorn); according to Bavendamm (Schwefelbakterien, Jena, 1924, 127) identical with *Chromatium warmingii* forma *minus*. Gicklhorn claims this organism to be colorless, which appears very doubtful.

Source: From the pond in the Annen Castle Park, Graz, Austria.

Habitat: Fresh water ponds.

Illustration: Gicklhorn, *loc. cit.*, fig. 2.

7. **Chromatium minus** Winogradsky. (Winogradsky, Schwefelbacterien, Leipzig, 1888, 99; *Bacillus minor* Trevisan, I generi e le specie delle Batteriacee, 1889, 18; *Bacterium minus* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1027.) From Latin *minus*, small.

Cells: 3 by 3.5 to 7 microns (Winogradsky); also 1.7 to 3 microns in width and up to 8.5 microns in length (Issatchenko, Borodin Jubilee Volume, 1929?, 9); all transitions to *Chromatium weissei* from which it cannot be distinguished (Strzeszewski, Bull. Acad. Sci., Cracovie, Sér. B, 1913, 321).

Illustrations: Winogradsky, *loc. cit.*, Pl. IV, fig. 5; Miyoshi, Jour. Coll. Sci., Imp. Univ., Tokyo, Japan, *10*, 1897, Pl. XIV, fig. 16; Issatchenko, Recherches sur les microbes de l'océan glacial arctique, Petrograd, 1914, Pl. II, fig. 10–11.

8. **Chromatium vinosum** (Ehrenberg) Winogradsky. (*Monas vinosa* Ehrenberg, Die Infusionstierchen, Leipzig, 1838, 11; Winogradsky, Schwefelbacterien, Leipzig, 1888, 99; *Bacillus vinosus* Trevisan, I generi e le specie delle Batteriacee, 1889, 18; *Bacterium vinosum* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1027.) From Latin *vinosus*, pertaining to wine, wine-colored.

Cells: 2 by 2.5 to 5 microns; also 1.4 to 3 by 1.5 to 5 microns (Jimbo, Botan. Magaz. Tokyo, *51*, 1937, 872); 1.7 to 2 by 2 to 9 microns (Issatchenko, Borodin Jubilee Volume, 1929?, 9); or 1 to 1.3 microns by 2.5 to 3 microns (Schrammeck, Beitr. Biol. d. Pflanzen, *22*, 1935, 317). Jimbo considers *Thioderma roseum* Miyoshi to be identical with *Chromatium vinosum*.

Illustrations: Winogradsky, *loc. cit.*, Pl. IV, 6–7; Miyoshi, Jour. Coll. Sci., Imp. Univ. Tokyo, Japan, *10*, 1897, Pl. XIV, fig. 17; Nadson, Bull. Jard. Imp. Botan., St. Pétersbourg, *12*, 1912, Pl. III, fig. 1–2.

9. **Chromatium violaceum** Perty. (Zur Kenntniss kleinster Lebensformen, Bern, 1852, 174.) From Latin *violaceus*, violet-colored.

Cells: About 2 by 2 to 3 microns. According to Cohn (Beitr. Biol. Pfl., *1*, Heft 3, 1875, 166) probably identical with *Chromatium vinosum*. Apparently includes various sizes.

10. **Chromatium molischii** (Bersa) *comb. nov.* (*Pseudomonas molischii* Bersa, Planta, *2*, 1926, 375.) Named for the Austrian botanist, H. Molisch.

Cells: About 2 by 2.5 to 8 microns. Supposedly contains calcium carbonate as inclusions.

Illustration: Bersa, *loc. cit.*, 376, fig. 3.

11. **Chromatium gracile** Strzeszewski. (Bull. Acad. Sci., Cracovie, Sér. B, 1913, 321.) From Latin *gracilis*, slender.

Cells: 1 to 1.3 by 2 to 6 microns; also to 1.5 micron in width (Issatchenko, Études microbiologiques des Lacs de Boue, Leningrad, 1927, 114).

Illustration: Strzeszewski, *loc. cit.*, Pl. XXXIX, fig. 1–2; Tokuda, Botan. Magaz., Tokyo, *50*, 1936, 339, fig. 1–23.

12. **Chromatium minutissimum** Winogradsky. (Winogradsky, Schwefelbac-

terien, Leipzig, 1888, 100; *Bacillus minutissimus* Trevisan, I generi e le specie delle Batteriacee, 1889, 18; *Bacterium minutissimum* DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1028.) From Latin *minutus* and diminutive, very minute.

Cells: About 1 to 1.2 micron by 2 microns. Also from 0.5 to 0.7 micron by 0.6 to 1 micron (Issatchenko, Recherches sur les microbes de l'océan glacial arctique, Petrograd, 1914, 253); and 1 to 3 microns by 2 to 5 microns (Issatchenko, Borodin Jubilee Volume, 1929?, 9).

Illustrations: Winogradsky, *loc. cit.*, Pl. IV, fig. 8; Miyoshi, Jour. Coll. Sci., Imp. Univ., Tokyo, Japan, *10*, 1897, Pl. XIV, fig. 18.

Appendix: The measurements for *Thiospirillum coccineum* Hama (Jour. Sci. Hiroshima Univ., Ser. B, Div. 2, Bot., *1*, 1933, 158) which, according to description and figures (*ibid.*, Pl. 18, fig. 2; Pl. 19, fig. 2), is an unquestionable species of *Chromatium*, are given as 2 by 4 to 15 microns. It thus closely resembles the bacteria of the *Chromatium minus*, *C. vinosum*, *C. violaceum*, and *C. molischii* group.

Chromatium sphaeroides Hama, *loc. cit.*

Thiospirillum violaceum (Warming) Winogradsky is probably also a member of this assemblage.

APPENDIX TO FAMILY THIORHODACAE.

Three genera of sulfur purple bacteria have been proposed whose place and nature are at present very doubtful. They follow here:

a. *Thiosphaerion* Miyoshi, with the single species *Thiosphaerion violaceum* Miyoshi (Jour. Coll. Sci., Imp. Univ., Tokyo, Japan, *10*, 1879, 170). Occurs in round colonies in which numerous bacteria are held together by mucus, though not in a clearly discernible common capsule. Individual cells ovoid, about 1.5 to 2 by 2.5 microns; motile. Resembles *Lamprocystis roseopersicina* in many respects. Reported once from Yumoto Hot Springs, near Nikko, Japan.

Illustrations: Miyoshi, *loc. cit.*, Pl. XIV, fig. 24 a-b.

b. *Pelochromatium* Lauterborn, with the single species *Pelochromatium roseum* Lauterborn (Verhandl. naturhist. medizin. Vereins, Heidelberg, N.F. *13*, 1915, 424). Forms small colonies in which the bacteria are regularly arranged in about 5 rows, from 2 to 4 cells high, around a colorless central body. The entire colony actively motile and behaves like a single unit. Individual cells bean- or vibrio-shaped, about 1 micron or less by 2 microns; the barrel-shaped colony measures 2.5 to 4 by 4 to 8 microns. The structure may represent a complex of a colorless central bacterium surrounded by purple bacteria, analogous to *Chlorochromatium aggregatum* Lauterborn. Whether such structures have generic or even specific taxonomic significance remains to be determined. The lack of information concerning the occurrence of sulfur globules in the cells makes it doubtful whether the organisms are sulfur purple bacteria at all. Found twice by Lauterborn in mud samples.

Illustrations: Lauterborn, *loc. cit.*, Pl. III, fig. 28, a-c.

Utermöhl suggested the name *Lauterborniola minima* Utermöhl (Biol. Zentralbl., *43*, 1924, 605) for the small brownish bacteria which form the covering of the central body of *Pelochromatium roseum*; according to this author the central body is a larger bacterium, 1.5 by 7 microns which he named *Endosoma palleum*.

c. *Thioporphyra* Ellis, with the single species *Thioporphyra volutans* Ellis (Jour. Roy. Technic. Coll. Glasgow,

1926, 165). The account of this pleomorphic organism, which is claimed to multiply by fission, budding, and probably spore formation, is wholly unconvincing. The shape and size of some of the cells make it appear likely that Ellis observed mixtures of various kinds of purple sulfur bacteria.

Illustrations: Ellis, *loc. cit.*, 166, fig. 1-14; 171, Micro. I; 172, Micro. II; Sulphur Bacteria, London and New York, 1932; 153, fig. 33; 154, fig. 34; 156, fig. 35; 158, fig. 36.

Finally, there exist some, as yet unnamed, red to purple bacteria which contain bacteriochlorophyll and carotenoid pigments, are capable of photosynthesis in the presence of hydrogen sulfide, but excrete elementary sulfur as an intermediate oxidation product instead of storing sulfur globules inside their cells (van Niel, Arch. f. Mikrobiol., *3*, 1931, 63). They are small motile rods, vibrios or spirilla, about 0.5 by 1 to 2 microns. They may also occur as spherical cells of about 1 micron in diameter. They can readily be grown in organic media, under anaerobic conditions, in illuminated cultures and may be included either with the sulfur purple bacteria or with the non-sulfur purple bacteria, among which *Rhodopseudomonas palustris* is equally capable of photosynthesis in the presence of reduced inorganic sulfur compounds.

FAMILY II. ATHIORHODACEAE MOLISCH.*

(Molisch, Die Purpurbakterien, Jena, 1907, 28; *Rhodobacterioideae* Buchanan, Jour. Bact., *3*, 1918, 471; *Athiorhodobacteria* Bavendamm, Ergeb. Biol., *13*, 1936, 49.)

Unicellular bacteria, of relatively small size, occurring as spheres, short rods, vibrios, long rods and spirals. Motility is due to the presence of polar flagella. Gram-negative. They produce a pigment system composed of bacteriochlorophyll and one or more carotenoids, coloring the cells yellowish-brown, olive brown, dark brown or various shades of red. Color usually not observable with single cells but only with cell masses. Generally microaerophilic, although many representatives may grow at full atmospheric oxygen tension. Capable of development under strictly anaerobic conditions, but only in illuminated cultures by virtue of a photosynthetic metabolism. The latter is dependent upon the presence of extraneous hydrogen donors, such as alcohols, fatty acids, hydroxy- and keto-acids, and does not proceed with the evolution of molecular oxygen. Those members which can grow in the presence of air can also be cultivated in darkness, but only under aerobic conditions.

Key to the genera of family **Athiorhodaceae.**

I. Cells rod-shaped or spherical, not spiral-shaped.
  Genus I. *Rhodopseudomonas*, p. 861.

II. Cells spiral-shaped.
  Genus II. *Rhodospirillum*, p. 866.

Genus I. **Rhodopseudomonas** *Kluyver and van Niel emend. van Niel.*

(Includes *Rhodobacillus* Molisch, Die Purpurbakterien, Jena, 1907, 14; *Rhodobacterium* Molisch, *ibid.*, 16; *Rhodococcus* Molisch, *ibid.*, 20; *Rhodovibrio* Molisch, *ibid.*, 21; *Rhodocystis* Molisch, *ibid.*, 22; *Rhodonostoc* Molisch, *ibid.*, 23; *Rhodosphaera* Buchanan, Jour. Bact., *3*, 1918, 472; *Rhodorrhagus* Bergey et al., Manual, 3rd ed., 1930, 535; *Rhodomonas* Kluyver and van Niel, Cent. f. Bakt., II Abt., *94*, 1936, 397; not *Rhodomonas* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 331; Kluyver and van Niel, in Czurda and Maresch, Arch. f. Mikrobiol., *8*, 1937, 119; van Niel, Bact. Rev., *8*, 1944, 86.) From Greek *rhodon*, red and *pseudomonas*, false unit.

Spherical and rod-shaped bacteria, motile by means of polar flagella. Gram-negative. Contain bacteriochlorophyll which enables them to carry out a photosynthetic metabolism. The latter is dependent upon the presence of extraneous oxidizable substances and proceeds without the evolution of molecular oxygen. Though some members can oxidize inorganic substrates, none appears to be strictly autotrophic, due to the need for special organic growth factors. Produce accessory pigments causing the cultures, especially when kept in light, to appear in various shades of brownish-yellow to deep red.

The genus includes the members of Molisch's genera *Rhodobacterium*, *Rhodobacillus*, *Rhodovibrio*, *Rhodocystis*, *Rhodonostoc* and *Rhodococcus*, as well as the genera *Rhodosphaera* Buchanan, *Rhodorrhagus* Bergey et al. and *Rhodomonas* Kluyver and van Niel.

The type species is *Rhodopseudomonas palustris* (Molisch) van Niel.

---

* Completely revised by Prof. C. B. van Niel, Hopkins Marine Station, Pacific Grove, California, January, 1944.

Keys to the species of genus **Rhodopseudomonas.**

I. Based upon morphological characters.
  1. Cells clearly rod-shaped in all media.
    a. Cells short, somewhat curved, to long branched rods, size of young and short cells 0.6 to 0.8 by 1.2 to 2 microns; in older cultures up to 10 microns long; do not form slime; liquid cultures, when young, or after shaking, evenly turbid. Color red to dark brown-red.
      1. *Rhodopseudomonas palustris.*
    aa. Cells slender rods, 0.5 by 1.2 microns usually clumped together in extensive slime masses. Cultures pale brown to peach-colored.
      2. *Rhodopseudomonas gelatinosa.*
  2. Cells more or less spherical in media at pH below 7.
    a. In media at pH about 7 clearly rod-shaped, 1 by 1 to 2.5 microns. Chains of cells frequent, and in characteristic zigzag arrangement.
      3. *Rhodopseudomonas capsulatus.*
    aa. In media at pH above 7 cells still predominantly spherical, 0.7 to 4 microns in diameter. Mostly single, little tendency to chain formation.
      4. *Rhodopseudomonas spheroides.*

II. Based chiefly on physiological properties.
  1. Gelatin liquefied.
      2. *Rhodopseudomonas gelatinosa.*
  2. Gelatin not liquefied.
    a. Does not produce mucus in media at pH above 8. Color the same under aerobic and anaerobic conditions of growth.
      1. *Rhodopseudomonas palustris.*
    aa. Produce mucus in media at pH above 8. Color brown in anaerobic, red in aerobic culture.
      b. Develops readily in media with 0.2 per cent propionate as the chief oxidation substrate. Mucus production marked at pH above 8, but very limited between 7 and 8.
        3. *Rhodopseudomonas capsulatus.*
      bb. Does not develop in media with 0.2 per cent propionate as the main oxidation substrate. Slime formation extensive at pH above 7.
        4. *Rhodopseudomonas spheroides.*

III. Based principally upon biochemical characters.
  1. Thiosulfate used as main oxidation substrate.
      1. *Rhodopseudomonas palustris.*
  2. Thiosulfate not used.
    a. Propionate (0.2 per cent) used.
      3. *Rhodopseudomonas capsulatus.*
    aa. Propionate not used.
      b. Mannitol and sorbitol (0.2 per cent) used.
        4. *Rhodopseudomonas spheroides.*
      bb. Mannitol and sorbitol not used.
        2. *Rhodopseudomonas gelatinosa.*

1. **Rhodopseudomonas palustris** (Molisch) van Niel. (*Rhodobacillus palustris* Molisch, *Rhodobacterium capsulatum* Molisch and *Rhodovibrio parvus* Molisch, Die Purpurbakterien, Jena, 1907, 14, 18 and 21; *Rhodomonas palustris* Kluyver and van Niel, Cent. f. Bakt., II Abt., *94*, 1936, 397; *Rhodopseudomonas* No. 9 and No. 16, Czurda and Maresch, Arch. f. Mikrobiol., *8*, 1937, 120; van Niel, Bact. Rev., *8*, 1944, 89.) From Latin *paluster*, boggy, marshy.

Cells: Usually distinctly rod-shaped, though in young cultures very short, lightly curved rods may often predominate. Size variable, even for the same strain, and strongly influenced by age of culture and composition of medium. Rather consistently short cells in young cultures in yeast extract, especially when incubated anaerobically in the light, or in anaerobic cultures with substrates which permit only a slow and scanty development, such as malonate. Dimensions in such cultures 0.6 to 0.8 by 1.2 to 2 microns. More often, especially in older cultures, cells are much longer, up to 10 microns. Highly characteristic is the pronounced tendency to the formation of irregularly shaped, bent and crooked long rods, occasionally swollen at one or both extremities, and frequently suggesting branching. Such cells usually form clusters reminiscent of *Corynebacterium* and *Mycobacterium* cultures.

Cells in young cultures actively motile by means of polar flagella; irregular and long cells as a rule non-motile. Gram-negative.

Growth in liquid media never mucoid; sediment in older cultures homogeneous and smooth, readily redispersible.

Color: Varies considerably, depending upon the medium, and especially in anaerobic illuminated cultures. Where development is slight (as in malonate, thiosulfate, and, usually, glycerol media), the color is a light pink; in fatty acid-containing media more nearly dark reddish-brown. Color due to bacteriochlorophyll and a number of different carotenoid pigments; most strains produce in addition a water-soluble, non-carotenoid, bluish-red pigment which diffuses into the culture medium.

In yeast extract cultures growth is possible over the range pH 6 to 8.5. With certain substrates, especially fatty acids, the combined effect of low pH and a substrate concentration of 0.1 to 0.2 per cent may prevent growth. No characteristic odors save that old cultures may develop a distinct ionone-like fragrance. Gelatin is not liquefied; leucine is generally utilized as a substrate.

Most strains are able to grow on the surface of agar plates or slants; a few, especially when first isolated, appear more sensitive to oxygen and develop only in stabs in which the upper region may remain free of growth. Generally such strains can be adapted to grow at full atmospheric oxygen tension.

Most fatty acids and hydroxy acids are adequate oxidation substrates. All cultures can grow at the expense of thiosulfate and produce rapid and profuse growth in glutarate and ethanol media. No development in media containing as the chief oxidation substrate 0.2 per cent sorbitol, glucose or mannose, even though these substances are not inhibitory. Molecular hydrogen can be oxidized.

All cultures can develop anaerobically in illuminated cultures by photosynthesis.

Temperature optimum generally rather high, good development being possible up to 37°C. However, certain strains exhibit a lower temperature optimum.

Distinguishing characteristics: Morphological resemblance to species of *Mycobacterium* in old cultures; ability to grow with thiosulfate as the chief oxidizable substrate, and failure to develop in media which contain carbohydrates or sugar alcohols in a concentration of 0.2 per cent as the main oxidizable compounds.

Habitat: Regularly found in mud and stagnant bodies of water.

Illustrations: Molisch, *loc. cit.*, Plate I, fig. 1, 2; Plate II, fig. 10; van Niel, *loc. cit.*, fig. 1–3, p. 18, and fig. 18–26, p. 90.

2. **Rhodopseudomonas gelatinosa** (Molisch) van Niel. (*Rhodocystis gelatinosa* Molisch, Die Purpurbakterien, Jena, 1907, 22; van Niel, Bact. Rev., *8*, 1944, 98.) From Latin *gelatio*, freezing, indicating solidification, or in this case, clumping.

Cells: In young cultures, short and small rods, approximately 0.5 by 1 to 2 microns. In old cultures much longer, up to 15 microns, and then irregularly curved rods, often swollen and gnarled in places up to 1 micron in width. In this stage the cells bear some resemblance to those found in old cultures of *Rhodopseudomonas palustris*, but the characteristic *Mycobacterium*-like clusters of the latter are absent. Single cells infrequent due to a copious mucus production in all media which causes the cells to clump together. While young cells are actively motile by means of polar flagella, motility is often difficult to ascertain as a result of the pronounced tendency to conglomerate; the individuals in the clumps appear to be non-motile. Gram-negative. Gelatin is liquefied; of the single amino acids alanine, asparagine, aspartic and glutamic acids appear generally satisfactory substrates.

Color: Quite distinctive in most anaerobic cultures as a pale, delicate, pinkish shade, rather peach-colored. Only in the presence of rather high concentrations of yeast extract (when a much heavier growth is obtained than with low concentrations supplemented with 0.2 per cent of various single oxidation substrates) do the slimy cell masses appear a dirty, faded brown. Color is due to bacteriochlorophyll and carotenoid pigments. Occasionally a water-soluble, non-carotenoid, bluish-red pigment is produced which diffuses into the culture medium.

In yeast extract, growth occurs over a pH range extending from at least 6.0 to 8.5.

Cultures produce a characteristic acrid odor.

More sensitive to fatty acids than other species of *Rhodopseudomonas*; with 0.2 per cent propionate no growth occurs. The best single oxidizable substrates appear to be ethanol, glucose, fructose and mannose, as well as a variety of amino acids. Citrate also permits good growth; not, on the other hand, glycerol, mannitol, sorbitol or tartrate in the usual concentration of 0.2 per cent.

Thiosulfate is not oxidized; behavior towards molecular hydrogen unknown.

More pronouncedly microaerophilic than the other *Rhodopseudomonas* species; most cultures cannot develop on aerobically incubated slants or agar plates.

Capable of strictly anaerobic development in illuminated cultures by virtue of a photosynthetic metabolism.

Temperature relations so far unknown.

Distinguishing properties: The small size of the individual cells, and the pronounced clumping which causes the cultures to be exceptionally stringy; the unusual color of the cell masses; the ability to liquefy gelatin, to utilize citrate and a number of amino acids. Correlated with these is the failure to grow in media with 0.2 per cent propionate, tartrate and glycerol.

Habitat: Regularly present in stagnant bodies of water and in mud.

Illustrations: Molisch, *loc. cit.*, Plate I, fig. 8; van Niel, *loc. cit.*, fig. 55–60, p. 99; fig. 61–66, p. 100.

3. **Rhodopseudomonas capsulatus** (Molisch) van Niel. (*Rhodonostoc capsulatum* Molisch, Die Purpurbakterien, Jena, 1907, 23; van Niel, Bact. Rev., *8*, 1944, 92.) From Latin *capsula*, container (sheath).

Cells: Depending upon the pH of the medium, cells nearly spherical, or as distinct rods, often devoid of motility. Motility due to polar flagella. The spherical cells are found in media with a pH below 7; they are usually arranged in chains resembling streptococci. Rod-shaped cells are characteristic for media with pH above 7; the higher the pH, the longer the rods. Individual cells slightly less than 1 micron wide, although attenuated rods (about 0.5 micron in width) are frequent at pH above 8, and slightly swollen cells (to 1.2 microns) are found in media containing sugars. Length varies from 1 to 6 microns; most common dimensions in approximately neutral media 2 to 2.5 microns. At pH above 8 abnormal growth in the form of irregular filaments. Outstandingly characteristic is the zigzag arrangement of the cells in chains.

Cultures in media of pH 8 or above are distinctly mucoid. Gram-negative.

Color: Anaerobic cultures develop with a brown color, the shade ranging from a light yellowish-brown to a deep mahogany brown. When grown in the presence of oxygen, the cultures are dark red. Even the pigmentation of the brown-colored organisms from an anaerobic culture can be changed into a distinct red by shaking a suspension with air for some hours; light enhances the rate of this color change. Color due to bacteriochlorophyll and carotenoid pigments. No diffusible water-soluble pigment is produced.

Growth possible over a pH range from at least 6 to 8.5, morphology becoming abnormal in the alkaline media.

Most cultures are odorless, although occasionally a faint peach-like odor can be detected.

Growth is not inhibited by the presence of oxygen, although the pigmentation is thereby affected.

Fatty acids and most substituted acids are satisfactory substrates. Rapid and abundant growth with propionate at a concentration of 0.2 per cent. At this same concentration glutaric acid leads, at best, to very meager cultures, while tartrate, citrate and gluconate fail to induce growth, as do also ethanol, glycerol, mannitol and sorbitol. In media with 0.2 per cent glucose or fructose good growth is obtained. No growth with mannose. Thiosulfate is not, but molecular hydrogen can be, oxidized by this species.

Gelatin is not liquefied; of the amino acids alanine and glutamic acid are satisfactory substrates, while leucine is not utilized.

Distinguishing properties: Cell shape and arrangement in chains; brown color of anaerobic, red pigmentation of aerobic cultures; ability to grow in media with 0.2 per cent propionate, glucose, fructose, alanine and glutamic acid; failure to develop with leucine, as well as with ethanol, glycerol, mannitol and sorbitol in the above-mentioned concentration.

All cultures can develop anaerobically in illuminated cultures by a photosynthetic metabolism.

Temperature optimum distinctly lower than for *Rhodopseudomonas palustris*, and, as a rule, around 25°C.

Habitat: Regularly found in stagnant bodies of water and in mud.

Illustrations: Molisch, *loc. cit.*, Plate II, fig. 9; van Niel, *loc. cit.*, fig. 4–6, p. 19; fig. 27–32, p. 92; and fig. 33–38, p. 93.

4. **Rhodopseudomonas spheroides** van Niel. (*Rhodococcus capsulatus* Molisch, Die Purpurbakterien, Jena, 1907, 20; *Rhodococcus minor* Molisch, *ibid.*, 21; *Rhodosphaera capsulata* Buchanan, Jour. Bact., *3*, 1918, 472; *Rhodosphaera minor* Bergey et al., Manual, 1st ed., 1923, 405; *Rhodorrhagus minor* Bergey et al., Manual, 3rd ed., 1930, 535; *Rhodorrhagus capsulatus* Bergey et al., Manual, 3rd ed., 1930, 535; van Niel, Bact. Rev., *8*, 1944, 95.) From Latin *sphaera*, a round body and Greek *eidos*, form of.

Cells: Generally single, nearly spherical, diameter without slime capsule variable, depending upon medium, ranging from 0.7 to 4 microns. In young cultures actively motile by means of polar flagella; motility soon ceases in media which are or become alkaline. Copious slime production in media at pH above 7. In strongly alkaline cultures abnormal cell-shapes occur in the form of irregular, swollen and distorted rods, often having the appearance of spore-bearing cells, simulated by the production of fat bodies. In sugar-containing media egg-shaped cells, measuring as a rule 2.0 to 2.5 by 2.5 to 3.5 microns, are frequently found. Gram-negative.

Color: Anaerobic cultures develop with brown color, ranging in shade from a light, dirty greenish-brown to a dark brown. Cultures grown in the presence of oxygen are distinctly red. As in the case of *Rhodopseudomonas capsulatus*, the brown color of an anaerobic culture can be changed to red by shaking with air, light stimulating the color change. Color due to bacteriochlorophyll and carotenoid pigments. The large majority of cultures of this species produces in addition a water-soluble, non-carotenoid, bluish-red pigment which diffuses into the culture medium.

Gelatin is not liquefied, and growth with single amino acids appears somewhat erratic. No definite correlations have been observed.

Development is possible over a wide pH range, extending from at least 6.0 to 8.5.

All cultures exhibit an unpleasant putrid odor.

Requires for optimal development higher concentrations of yeast extract as a supply of growth factors than either *Rhodopseudomonas palustris* or *Rhodopseudomonas capsulatus* and is more sensitive to low fatty acid concentrations. With 0.2 per cent propionate in a neutral medium, no growth occurs; caproic and pelargonic acids are toxic in concentrations below 0.1 per cent. On the other hand, tartrate and gluconate can serve as oxidation substrates, as can also ethanol, glycerol, mannitol, sorbitol, glucose, fructose and mannose in 0.2 per cent concentrations.

In sugar-containing media, acid is produced; the pH may drop to below 4.0 before development ceases. Acid production from glucose occurs both in presence and absence of air, and in illuminated as well as in non-illuminated cultures. In cultures exposed to light, the acid usually disappears later on.

Thiosulfate is not oxidized; hydrogen oxidation has not been observed.

Oxygen does not prevent growth; colonies develop on the surface of agar plates exposed to air, with a red pigmentation. Capable of strictly anaerobic development in illuminated cultures by photosynthesis.

Temperature optimum below 30°C.

Distinguishing properties: Spherical cell-shape in most media; brown color of anaerobic and red pigmentation of aerobic cultures; growth with 0.2 per cent tartrate, gluconate, ethanol, glycerol, mannitol, sorbitol, glucose, fructose and mannose; failure to grow with 0.2 per cent propionate.

Habitat: Regularly found in stagnant bodies of water and in mud.

Illustrations: Molisch, *loc. cit.*, Plate II, fig. 15; van Niel, *loc. cit.*, fig. 7–8, p. 19; fig. 39–45, p. 96; fig. 46–54, p. 97.

Genus II. **Rhodospirillum** *Molisch emend. van Niel.*

(Molisch, Die Purpurbakterien, Jena, 1907, 24; van Niel, Bact. Rev., *8*, 1944, 86; the genus now includes the genus *Phaeospirillum* Kluyver and van Niel, Cent. f. Bakt., II Abt., *94*, 1936, 396.) From Greek *rhodon*, red and M.L. *spirillum*, spirillum.

Spiral-shaped bacteria, motile by means of polar flagella. Gram-negative.

Contain bacteriochlorophyll and are potentially photosynthetic in the presence of extraneous oxidizable substances. Molecular oxygen is not produced. Unable to grow in strictly mineral media, even when possessed of the ability to utilize hydrogen as oxidizable substrate, due to the need for organic nutrilites. Produce accessory pigments causing the cultures, especially when grown in the light, to appear in various shades of red to brown.

The type species is *Rhodospirillum rubrum* (Esmarch) Molisch.

Key to the species of genus **Rhodospirillum.**

I. Cultures red; cells well over 0.5 micron, usually about 1 to 1.2 microns in width.
1. *Rhodospirillum rubrum.*

II. Cultures brown to orange; cells 0.5 micron or less in width.
2. *Rhodospirillum fulvum.*

1. **Rhodospirillum rubrum** (Esmarch) Molisch. (*Spirillum rubrum* Esmarch, Cent. f. Bakt., *1*, 1887, 225; Molisch, Die Purpurbakterien, Jena, 1907, 25; *Rhodospirillum photometricum* Molisch, *ibid.*, 24; *Rhodospirillum giganteum* Molisch, *ibid.*, 24; *Rhodospirillum longum* Hama, Jour. Sci. Hiroshima Univ., Ser. B, Div. 2, *1*, 1933, 135; *Rhodospirillum gracile* Hama, *ibid.*, 159.) From Latin *ruber*, red.

Cells: Characteristically spiral-shaped, but size of elements variable within wide limits, depending upon environmental conditions during growth. Width of cells from 0.5 to 1.5 microns; length from 2 to 50 microns, and over; even in a single culture such differences may be found. Also the shape and size of the spiral coil varies much; it usually ranges between 1 to 4 microns in width, and from 1.5 to 7 microns in length. In alanine media the majority of the cells occurs in the form of half-circles to complete rings; malate media tend to produce much flattened spirals.

In old cultures involution forms appear, straightened spirals and irregularly swollen cells, the latter common in media with higher fatty acids. Such cells stain irregularly, contain fatty inclusions, and are occasionally branched.

Mucus is not produced. In calcium-deficient media the growth is flocculent, as if agglutinated. With an adequate calcium supply the growth in liquid media is homogeneous, suspended, and consists of single cells.

Young cultures show active motility, due to polar flagella. Gram-negative.

Gelatin is not liquefied; the amino acids alanine, asparagine, aspartic and glutamic acids are satisfactory oxidizable compounds.

Color: Ordinarily deep and dark red, without any brownish tinge. In ethanol media lighter, and a characteristic pink. Pigment production markedly influenced by oxygen and light. Slants incubated in darkness present a pale grayish surface growth with a faint reddish hue, while often showing deep-red cell masses in the region between glass wall and agar surface where development proceeds at low oxygen tension. The color is due to bacteriochlorophyll and carotenoid pigments. Among the latter spirilloxanthin is quantitatively predominant. Water-soluble, diffusible pigments are not produced.

Development possible over a pH range of at least 6 to 8.5, although, as in other cases, the combination of an acid reaction and the presence of fatty acids may prevent growth.

Cultures produce a distinctive odor, reminiscent of slightly putrid yeast.

In general, grow well with fatty acids as the chief oxidizable substrate; however, are prevented from growing by 0.2 per cent propionate in a neutral medium. Most substituted acids are equally satisfactory, with the exception

of tartrate, gluconate and citrate. In a concentration of 0.2 per cent, ethanol is a suitable substrate, whereas the carbohydrates and their corresponding polyalcohols are not utilized.

Thiosulfate is not oxidized; molecular hydrogen can be used by some strains.

Rather microaerophilic; many strains upon initial isolation incapable of growth at atmospheric oxygen tension. Subsequent adaptation can be induced. But even such adapted cultures exhibit negative chemotaxis to air.

Capable of strictly anaerobic development in illuminated cultures on the basis of a photosynthetic metabolism.

Temperature optimum generally between 30° and 37°C.

Distinguishing properties: The most important characteristics of the species are the spiral shape, combined with the ability to produce a red pigment with a definite absorption maximum at 550 millimicrons in the intact cells. Diagnostically useful are the good growth in media with 0.2 per cent ethanol, alanine, asparagine, aspartate or glutamate, and the inadequacy of similar concentrations of carbohydrates and thiosulfate as substrates.

Habitat: Regularly present in stagnant bodies of water and in mud.

Illustrations: Molisch, *loc. cit.*, Plate I, fig. 5-7; van Niel, Bact. Rev., *8*, 1944, fig. 9–10, p. 19; fig. 11–16, p. 24; fig. 67–75, p. 103; fig. 76-84, p. 104; fig. 85–90, p. 106; fig. 91–96, p. 107.

2. **Rhodospirillum fulvum** van Niel. (Bact. Rev., *8*, 1944, 108.) From Latin *fulvum*, yellowish, tawny.

Characteristic for the species is the very small size of the individual cells. These are not over 0.5 micron wide, and generally not longer than 2.5 microns. The most common shape consists of a complete turn of about 1 by 1.5 microns. In media with fatty acids as a substrate the spirals appear somewhat steeper than in fumarate, succinate or malate cultures. Swollen individuals resembling vibrios are encountered in cultures which do not appear quite healthy. Formation of mucus or clumping has not been observed.

Gelatin is not liquefied; aspartate has been the only amino acid capable of inducing growth. Thiosulfate is not oxidized.

Color: Quite distinct from that of *Rhodospirillum rubrum*; colonies and stab cultures are a reddish-brown, while liquid cultures often appear brownish-orange. The color is due to bacteriochlorophyll and carotenoid pigments; among the latter spirilloxanthin, as evidenced by the absence of an absorption maximum at 550 millimicrons, is not represented as a major constituent. Does not produce water-soluble, diffusible pigments.

Capable of strictly anaerobic development in illuminated cultures, due to photosynthetic metabolism.

Fatty acids and the four-carbon dicarboxylic acids are uniformly good substrates; glutarate is not used. Ethanol and glucose, in a concentration of 0.2 per cent, have yielded satisfactory cultures; other carbohydrates, as well as the corresponding polyalcohols, have given negative results.

Little information available concerning pH and temperature relations. Behaves generally as a strict anaerobe; adaptation to microaerophilic conditions has not been achieved. Negative aerotaxis very pronounced.

Distinguishing properties: The small size and the color of the cultures serve as adequate criteria for its differentiation from *Rhodospirillum rubrum*. The strictly anaerobic nature and the failure to grow with glutarate and various amino acids except aspartate can probably be used as supplementary specific properties.

Habitat: Bodies of stagnant water and mud.

Illustrations: Van Niel, *loc. cit.*, fig. 97–102, p. 109.

FAMILY III. CHLOROBACTERIACEAE GEITLER AND PASCHER.*

(*Cyanochloridinae-Chlorobacteriaceae* Geitler and Pascher, Die Süsswasserflora Deutschlands, Österreichs und der Schweiz, Jena, *12*, 1925, 451; *Chlorothiobacteria* Bavendamm, Ergeb. Biol., *13*, 1936, 49.)

Green bacteria, usually of small size, occurring singly or in cell masses of various shapes and sizes, developing in environments containing rather high concentrations of hydrogen sulfide and exposed to light. As a rule not containing sulfur globules but frequently depositing elementary sulfur outside the cells. Contain green pigments of a chlorophyllous nature, though not identical with the common green plant chlorophylls nor with bacteriochlorophyll. Capable of photosynthesis in the presence of hydrogen sulfide; do not liberate oxygen.

A number of genera have been proposed, characterized by special colonial growth forms, others on the basis of a supposed symbiotic habitus, where the green bacteria grow in more or less characteristic aggregates together with other micro-organisms. In view of the variations in size and shape exhibited by the only member of this group which has so far been obtained and studied in pure culture (van Niel, Arch. f. Mikrobiol., *3*, 1931, 65ff.) the validity of many of these genera is doubtful. The following keys and descriptions, therefore, bear a strictly provisional character. Here, as in the case of the sulfur purple bacteria, significant advances can only be expected from pure culture studies under controlled environmental conditions.

Key to the genera of family **Chlorobacteriaceae.**

I. Free-living bacteria not intimately associated with other microbes.
  a. Bacteria not united into well defined colonies.
    Genus I. *Chlorobium*, p. 869.
  aa. Bacteria united into characteristic aggregates.
    b. Bacteria without intracellular sulfur globules.
      Genus II. *Pelodictyon*, p. 870.
    bb. Bacteria with intracellular sulfur globules.
      Genus III. *Clathrochloris*, p. 872.
II. Green bacteria found as symbiotic aggregates with other organisms.
  a. Aggregates composed of green bacteria and protozoa.
    Genus IV. *Chlorobacterium*, p. 872.
  aa. Aggregates composed of two different types of bacteria.
    b. Aggregates small, barrel-shaped, actively motile, and consisting of a central, polarly flagellated, rod-shaped bacterium with a covering of green sulfur bacteria.
      Genus V. *Chlorochromatium*, p. 873.
    bb. Aggregates large, cylindrical, non-motile, and composed of a central filamentous bacterium with a more or less extensive covering of green sulfur bacteria.
      Genus VI. *Cylindrogloea*, p. 873.

Genus I. **Chlorobium** *Nadson.*

(Nadson, Bull. Jard. Impér. Botan., St. Pétersb., *12*, 1912, 64 (Russian), 83 (German); *Chloronostoc* Pascher, Die Süsswasserflora Deutschlands, Österreichs und der Schweiz, Jena, *12*, 1925, 456; *Tetrachloris* Pascher, *ibid.*, 455; *Sorochloris*? Pascher,

* Completely revised by Prof. C. B. van Niel, Hopkins Marine Station, Pacific Grove, California, January, 1944.

ibid., 455; *Chloropseudomonas*? Czurda and Maresch, Arch. f. Mikrobiol., *8*, 1937, 123; in part, *Pelogloea* Lauterborn, Verhandl. naturhistor.-medizin. Vereins, Heidelberg, N.F. *13*, 1915, 430.) From Greek *chloros*, green and *bios*, life.

Green sulfur bacteria, occurring singly or in chains, individual cells of various sizes and shapes, from spherical to relatively long rod-shaped, the latter sometimes coiled into tight spirals; often united in chains, and generally embedded in a slime capsule. Non-motile. Contain a chlorophyllous pigment different from the common green plant chlorophylls and from bacterio-chlorophyll. Capable of photosynthesis in the presence of hydrogen sulfide, during which they produce elementary sulfur which is excreted outside the cells. Do not form spores.

The type species is *Chlorobium limicola* Nadson.

1. **Chlorobium limicola** Nadson. (Nadson, Bull. Jard. Impér. Botan., St. Pétersb., *12*, 1912, 64 (Russian), 83 (German); *Chloronostoc abbreviatum* Pascher, Süsswasserflora Deutschlands, Österreichs und der Schweiz, Jena, *12*, 1925, 456; *Tetrachloris inconstans* Pascher, *ibid.*, 456; *Sorochloris aggregata*? Pascher, *ibid.*, 455; in part *Pelogloea chlorina* Lauterborn, Verhandl. naturhistor.-medizin. Vereins, Heidelberg, N.F. *13*, 1915, 430.) From Latin, mud-dweller.

Cells: Various shapes and sizes, markedly dependent upon environmental conditions. In young and healthy state predominantly spherical to ovoid, about 0.5 to 1 micron in diameter, frequently united in chains resembling streptococci. Often cells become elongated and appear as rods, generally about 0.7 micron by 1 to 2.5 microns; also these may remain united in chains. Regularly produce mucus, causing the formation of cell-conglomerates of different size and shape, but not, as a rule, of characteristic appearance.

Color yellowish-green. Non-motile.

Abnormal cell forms (involution forms) rather common. These may be larger spherical cells, up to 5 to 6 microns in diameter, the larger ones generally vacuolated, or long rods, occasionally club-shaped but more often coiled. In rare cases the latter may be loosely wound. More frequently they are tightly-coiled screws, with cells of about 0.5 micron in diameter by as much as 15 microns in length. The spherical involution forms are normally encountered in acid, the coiled ones in alkaline environments.

Strictly anaerobic and apparently dependent upon hydrogen sulfide and light. Development in organic media has not been obtained.

Habitat: Mud and stagnant water containing rather high concentrations of hydrogen sulfide and exposed to light; more rarely in sulfur springs.

Illustrations: Nadson, *loc. cit.*, Pl. III, fig. 3–12; van Niel, Arch. f. Mikrobiol., *3*, 1931, 66, fig. 8.

Genus II. **Pelodictyon** *Lauterborn.*

(Lauterborn, Allgem. botan. Ztschr., *19*, 1913, 98; Verhandl. naturhistor.-medizin. Vereins, Heidelberg, N.F. *13*, 1915, 431; *Schmidlea loc. cit.*, Lauterborn, Allgem. botan. Zeitschr., *19*, 1913, 97; in part, *Pelogloea* Lauterborn, Verhandl. naturhist.-medizin Vereins, Heidelberg, N.F. *13*, 1915, 430; *Pediochloris* Geitler, Die Süsswasserflora Deutschlands, Österreichs und der Schweiz, Jena, *12*, 1925, 457.) From Greek *pelos*, mud and *dictyon*, net.

Green sulfur bacteria, individual cells ovoid to distinctly rod-shaped, producing rather extensive mucoid capsules, and generally united into large colonies of characteristic shapes. Non-motile. Contain chlorophyllous pigments different from

the common green plant chlorophylls and from bacteriochlorophyll. Capable of photosynthesis in the presence of hydrogen sulfide, but do not store sulfur globules inside the cells.

The type species is *Pelodictyon clathratiforme* (Szafer) Lauterborn.

Key to the species of genus **Pelodictyon.**

I. Cells united in colonies in a net-like fashion.
 1. *Pelodictyon clathratiforme.*

II. Cells arranged in tightly packed colonies without net-like structure.
 a. Colonies composed of irregularly arranged cell-masses, extending in three dimensions.
  2. *Pelodictyon aggregatum.*
 aa. Colonies consisting of parallel strands and extending in two dimensions.
  3. *Pelodictyon parallelum.*

1. **Pelodictyon clathratiforme** (Szafer) Lauterborn. (*Aphanothece clathratiforme* Szafer, Bull. Acad. Sci., Cracovie, Sér. B, *3*, 1910, 162; Lauterborn, Allgem. botan. Ztschr., *19*, 1913, 98; Lauterborn, Verhandl. naturhist.-medizin. Vereins, Heidelberg, N.F. *13*, 1915, 430; *Pelodictyon clathratiforme* Geitler, Die Süsswasserflora Deutschlands, Österreichs und der Schweiz, Jena, *12*, 1925, 458; *Pelodictyon lauterbornii* Geitler, *ibid.*, 458.) From Greek *clathros*, trellis and *formis*, shape.

Cells: Generally rod-shaped, ranging from slightly elongated ovoids to distinct rods, often vacuolated, about 0.5 to 1.5 micron by 2 to 4 microns, producing rather wide slime capsules, and characteristically united into three-dimensional colonies which present a net-like appearance, with mazes of about 10 to 50 microns.

Color yellowish-green. Non-motile.

Abnormal cell forms (involution forms) not uncommon, consisting of elongated and curved, forked, or club-shaped and swollen rods, occasionally suggesting rudimentary branching at the extremities. Such cells may be found as elements in chains for the greater part composed of normal individuals.

Habitat: Mud and stagnant water containing rather high concentrations of hydrogen sulfide and exposed to light; sulfur springs.

Illustrations: Szafer, *loc. cit.*, Pl. VI, fig. 5; Perfiliev, Jour. Microbiol. (Russian), *1*, 1914, Pl. II, fig. 1, 5–12; Lauterborn, *loc. cit.*, 1915, Pl. III, fig. 33.

2. **Pelodictyon aggregatum** Perfiliev. (*Aphanothece luteola* Schmidle, Beihefte Botan. Cent., *10*, 1901, 179; *Schmidlea luteola* Lauterborn, Allgem. botan. Ztschr., *19*, 1913, 97; Lauterborn, Verhandl. naturhistor.-medizin. Vereins, Heidelberg, N.F., *13*, 1915, 429; *Pelogloea bacillifera* Lauterborn, *ibid.*, 430; Perfiliev, Jour. Microbiol. (Russian), *1*, 1914, 197.) From Latin *aggregatus*, leading together, grouping.

Cells: Usually rod-shaped, about 1 to 1.5 microns by 2 to 4 microns, often vacuolated, producing mucus capsules, and united into irregularly shaped, three-dimensional colonies in which the cells are more or less tightly packed, without orderly arrangement. Colonies may attain a size of up to 1 mm; frequently they are not fully compact, but contain less dense areas, or appear perforated, thus forming transition stages to *Pelodictyon clathratiforme.*

Color yellowish-green. Non-motile.

Abnormal cell forms (involution forms) usually in the shape of elongated and curved, forked or club-shaped and swollen rods, occasionally suggesting branching at extremities.

Habitat: Mud and stagnant water, containing rather high concentrations of

hydrogen sulfide, and exposed to light; sulfur springs.

Illustrations: Perfiliev, *loc. cit.*, Pl. II, fig. 2; Lauterborn, *loc. cit.*, Pl. III, fig. 29–31.

3. **Pelodictyon parallelum** Perfiliev. (*Aphanothece parallela* Szafer, Bull. Acad. Sci., Cracovie, Sér. B, *3*, 1910, 163; Perfiliev, Jour. Microbiol. (Russian), *1*, 1914, 198; *Pediochloris parallela* Geitler, Die Süsswasserflora Deutschlands, Österreichs und der Schweiz, Jena, *12*, 1925, 457.) From Latin *parallelus*, beside one another.

Cells: Rather small, spherical to ovoid, or even rod-shaped; about 0.5 to 1 micron by 1 to 3 microns, occurring in chains, and forming flat, plate-like, two-dimensional aggregates in which the chains are arranged as parallel strands.

Color yellowish-green. Non-motile.

Abnormal cell forms not specifically mentioned, but likely to occur, and to resemble those of other species.

This species may well be a special growth-form of *Chlorobium limicola*.

Habitat: Mud and stagnant water containing rather high concentrations of hydrogen sulfide and exposed to light; sulfur springs.

Illustrations: Szafer, *loc. cit.*, Pl. VI, fig. 7; Perfiliev, *loc. cit.*, Pl. II, fig. 2.

Genus III. Clathrochloris *Geitler.*

(Die Süsswasserflora Deutschlands, Österreichs und der Schweiz, Jena, *12*, 1925, 457.) From Greek *clathros*, trellis and *chloros*, green.

Green sulfur bacteria of small size, generally spherical, and arranged in chains which are united into loose, trellis-shaped aggregates, somewhat similar to those of *Pelodictyon clathratiforme* and *Pelodictyon aggregatum*. Cells usually contain sulfur globules. Color yellowish-green. Non-motile.

The type species is *Clathrochloris sulphurica* (Szafer) Geitler.

1. **Clathrochloris sulphurica** (Szafer) Geitler. (*Aphanothece sulphurica* Szafer, Bull. Acad. Sci., Cracovie, Sér. B, *3*, 1910, 162; Geitler, Die Süsswasserflora Deutschlands, Österreichs und der Schweiz, Jena, *12*, 1925, 457.) From Latin, containing sulfur.

Cells: Spherical, about 0.5 to 0.7 micron in diameter, usually containing sulfur globules. Color yellowish-green. Non-motile.

The reported occurrence of sulfur globules in the cells of this very small species is surprising; it is the only one among the green sulfur bacteria in which these inclusions have been encountered. The published descriptions are even more fragmentary than those of other members of the group.

Source: Reported only from sulfur springs in Lubién Wielki, near Lwow, Poland.

Habitat: Mud and stagnant water containing rather high concentrations of hydrogen sulfide and exposed to light; sulfur springs.

Illustration: Szafer, *loc. cit.*, Pl. VI, fig. 6.

Genus IV. Chlorobacterium *Lauterborn.*

(Lauterborn, Verhandl. naturhist.-medizin. Vereins, Heidelberg, N.F., *13*, 1915, 429; not *Chlorobacterium* Guillebeau, Landw. Landw. Jahrb. d. Schweiz, *4*, 1890, 32; *Chroostipes* Pascher, Die Süsswasserflora Deutschlands, Österreichs und der Schweiz, Jena, *12*, 1925, 116.) From Greek *chloros*, green and Latin *bacterium*, a small rod.

Green sulfur bacteria(?) which grow symbiotically as an outside covering on cells of protozoa, such as amoeba and flagellates. Cells rod-shaped, often slightly curved, greenish. Non-motile.

The type species is *Chlorobacterium symbioticum* Lauterborn.

1. **Chlorobacterium symbioticum** Lauterborn. (Lauterborn, Verhandl. naturhist.-medizin. Vereins, Heidelberg, N.F., *13*, 1915, 429; *Chroostipes linearis* Pascher, Die Süsswasserflora Deutschlands, Österreichs und der Schweiz, Jena, *12*, 1925, 116.) From Greek, living symbiotically.

Cells: Rod-shaped, about 0.5 by 2 to 5 microns, often slightly curved. Non-motile.

Occur as a peripheral covering of certain protozoa with which they may form a symbiotic unit.

It is not certain that this is a green sulfur bacterium; the description of localities where it was found fail to mention the presence of hydrogen sulfide in the environment which should be a prerequisite for a member of this group.

Source: Reported from a number of pools in Germany.

Habitat: Stagnant water.

Illustrations: Lauterborn, *loc. cit.*, Pl. III, fig. 34–36; Pascher, *loc. cit.*, fig. 149.

Genus V. Chlorochromatium *Lauterborn.*

(Lauterborn, Allgem. botan. Ztschr., *19*, 1906, 196; *Chloronium* Buder, Ber. d. deut. bot. Ges., *31*, 1914, Generalversammlungsheft, 80.) From Greek *chloros*, green and *chroma*, color.

Green sulfur bacteria, ovoid to rod-shaped with rounded ends, occurring as barrel-shaped aggregates, consisting of a rather large colorless bacterium with a polar flagellum as the center, surrounded by the green bacteria, arranged in 4 to 6 rows, ordinarily from 2 to 4 cells high. The entire conglomerate behaves like a unit, is motile, and multiplies by the more or less simultaneous fission of its components.

The green constituents contain a chlorophyllous pigment which is not identical with the common green plant chlorophylls or with bacteriochlorophyll. Capable of photosynthesis in the presence of hydrogen sulfide, but do not store sulfur globules in the cells.

The type species is *Chlorochromatium aggregatum* Lauterborn.

1. **Chlorochromatium aggregatum** Lauterborn. (Lauterborn, Allgem. botan. Ztschr., *19*, 1906, 196; *Chloronium mirabile* Buder, Ber. deut. botan. Ges., *31*, 1914, Generalversammlungsheft, 80.) From Latin *aggregatus*, grouped.

Cells of the green component 0.5 to 1.0 by 1.0 to 2.5 microns, mostly from 8 to 16 individuals surrounding the central bacterium. Size of the total barrel-shaped unit variable, generally 2.5 to 5 by 7 to 12 microns. Occasionally a group of the complex colonies may remain attached in a chain.

Anaerobic.

Habitat: Mud and stagnant water containing rather high concentrations of hydrogen sulfide and exposed to light.

There is at present no good reason for distinguishing 2 varieties (forma *typica* and forma *minor*) or even species, on the basis of size differences of the colony, as Geitler proposed (Die Süsswasserflora Deutschlands, Österreichs und der Schweiz, Jena, *12*, 1925, 460). The reported and personally observed sizes of such units show that the extreme limits are linked by a complete series of transitions.

Illustrations: Buder, *loc. cit.*, Pl. XXIV, fig. 1–5; Perfiliev, Jour. Microbiol. (Russian), *1*, 1914, 213, fig. 1–5.

Genus VI. Cylindrogloea *Perfiliev.*

(Jour. Microbiol. (Russian), *1*, 1914, 223.) From Latin *cylindrus*, cylinder and Greek *gloios*, a glutinous substance.

Green sulfur bacteria, consisting of small ovoid to rod-shaped cells, growing in association with a filamentous, colorless, central bacterium, thus forming colonies of a cylindrical shape. Non-motile. The green component contains a chlorophyllous pigment different from the common chlorophylls of green plants and from bacteriochlorophyll. Capable of photosynthesis in the presence of hydrogen sulfide, without depositing sulfur globules in the cells.

The type species is *Cylindrogloea bacterifera* Perfiliev.

1. **Cylindrogloea bacterifera** Perfiliev. (Jour. Microbiol. (Russian), *1*, 1914, 223.) From Latin *bacter*, rod and *fero*, to bear.

Individual green components ovoid to rod-shaped, about 0.5 to 1 by 2 to 4 microns, very similar to those of the complex *Chlorobacterium symbioticum* and *Chlorochromatium aggregatum* with which they may well be identical. The central filamentous bacterium is embedded in a slime capsule of considerable dimensions. This, in turn, is surrounded by a layer of green bacteria, usually one cell thick. The green organisms may form a very dense outer covering, or they may be more sparsely distributed over the mucus capsule. The entire unit is again surrounded by a sizeable slime zone. Aggregates measure about 7 to 8 microns in width, and up to 50 microns in length; they are non-motile. Both components appear to be non-spore-forming.

Habitat: Mud and stagnant water containing rather high concentrations of hydrogen sulfide and exposed to light.

Illustration: Perfiliev, *loc. cit.*, 213, fig. 6–11.

Perfiliev rightly emphasizes, as Buder had done for *Chloronium mirabile*, the provisional nature of thus using a generic designation for an apparently stable complex composed of two different organisms. It remains possible that the last three genera of symbiotic entities represent fortuitous combinations whose occurrence is conditioned by environmental factors. If so, the generic terminology would be devoid of any taxonomic significance, and the green bacteria should be relegated to more appropriate genera. Indications suggestive of this state of affairs can be found in the literature; for example in Utermöhl's observation (Archiv f. Hydrobiol., Suppl. *5*, 1925, 279) that the complex *Chlorochromatium aggregatum* may, especially in the presence of oxygen, disintegrate, whereupon the green constituents appear as small *Pelodictyon aggregatum* (*Schmidlea luteola*) colonies.

ORDER II. ACTINOMYCETALES BUCHANAN.

(Jour. Bact., *2*, 1917, 162.)

Organisms forming elongated cells which have a definite tendency to branch. These hyphae do not exceed 1.5 microns and are mostly about 1 micron or less in diameter. In the *Mycobacteriaceae* the mycelium is rudimentary or absent; no spores are formed; the cells are acid-fast. The *Actinomycetaceae* and *Streptomycetaceae* usually produce a characteristic branching mycelium and multiply by means of special spores, oidiospores or conidia. Special spores are formed by fragmentation of the plasma within straight or spiral-shaped spore-bearing hyphae; the oidiospores are formed by segmentation, or by transverse division of hyphae, similar to the formation of oidia among the true fungi; the conidia are produced singly, at the end of simple or branching conidiophores. They grow readily on artificial media and form well-developed colonies. The surface of the colony, especially in the *Actinomycetaceae* and *Streptomycetaceae*, may become covered with an aerial mycelium. Some form colorless or white colonies, whereas others form a variety of pigments. Some species are partially acid-fast. In relation to temperature, most are mesophilic, while some are thermophilic. Certain forms are capable of growing at low oxygen tension. The Order as a whole is composed of saprophytic species, but also includes species that are parasitic and sometimes pathogenic on both animals and plants.

Key to the families of order **Actinomycetales.**

I. Mycelium rudimentary or absent, no spores formed. Acid-fast.

Family I. *Mycobacteriaceae*, p. 875.

II. True mycelium produced.

A. Vegetative mycelium divides by segmentation into bacillary or coccoid elements. Some species partially acid-fast.

Family II. *Actinomycetaceae*, p. 892.

B. Vegetative mycelium normally remains undivided.

Family III. *Streptomycetaceae*, p. 929.

Among the recent systems of classification of this order it is sufficient to mention the following: Baldacci (Mycopath., *2*, 1939, 84) divided the order *Actinomycetales* into two families: (a) *Mycobacteriaceae* Chester with two subfamilies, *Leptotrichioideae* Baldacci and *Proactinomycoideae* Baldacci, each with five genera, and (b) *Actinomycetaceae* Buchanan, with two genera, *Micromonospora* and *Actinomyces*. Krassilnikov (Ray fungi and related organisms, Izd. Akad. Nauk, Moskow, 1938) divided the order into (a) *Actinomycetaceae*, with four genera, *Actinomyces*, *Proactinomyces*, *Mycobacterium* and *Mycococcus*, and (b) *Micromonosporaceae*, with one genus, *Micromonospora*. Waksman (Jour. Bact., *39*, 1940, 549) divided the order into four families: *Mycobacteriaceae*, *Proactinomycetaceae*, *Actinomycetaceae* and *Micromonosporaceae*.

FAMILY I. MYCOBACTERIACEAE CHESTER.*

(Chester, Man. Determ. Bact., 1901, 349; *Proactinomycetaceae* Lehmann and Haag, in Lehmann and Neumann, Bákt. Diag., 7 Aufl., *2*, 1927, 674.)

---

* Completely revised by Prof. G. B. Reed, Queens University, Kingston, Ontario, Canada, December, 1938; minor revisions, December, 1944; with a complete revision of *Mycobacterium leprae* and *M. lepraemurium* by Dr. John H. Hanks, Leonard Wood Memorial, American Leprosy Foundation, New York, N. Y.

Slender filaments, straight or slightly curved rods, frequently irregular in form with only slight and occasional branching. Often stain unevenly, i.e., show variations in staining reaction within the cell (beading). No conidia. Non-motile. Aerobic. Gram-positive. Acid-fast.† Pathogenic species grow slowly (several weeks); those from soil, water and vegetation more rapidly (several days).

There is a single genus *Mycobacterium* Lehmann and Neumann.

Genus I. **Mycobacterium** *Lehmann and Neumann.*

(*Coccothrix* Lutz, Zur Morphologie des Mikroorganismus der Lepra. Dermatologische Studien, Heft 1, 1886, 22; *Schlerothrix* Metschnikoff, Arch. f. path. Anat. u. Physiol., *113*, 1888, 70; Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 108; *Mycomonas* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 329; *Eumyces* Battaglia, Soc. Internaz. Microbiol. Boll. Sez. Ital., *10*, 1938, 166.) From Greek *myces*, fungus and *bacterium*, a little rod.

Characters as for the family.

The type species is *Mycobacterium tuberculosis* (Schroeter) Lehmann and Neumann.

Key to the species of genus **Mycobacterium.**

I. Parasites in warm-blooded animals; grow slowly on all media.
  A. Grow slowly on glycerol agar in atmospheric air; experimentally infect guinea pigs and fowls.
    1. Experimentally produces generalized tuberculosis in guinea pigs but not in rabbits and fowls. Growth enhanced by the addition of glycerol to most media. Generally pale yellow to orange pigmentation on serum media.
      1a. *Mycobacterium tuberculosis* var. *hominis.*
    2. Experimentally produces generalized tuberculosis in guinea pigs and rabbits but not in fowls. Growth not enhanced by addition of glycerol to media. Never pigmented.
      1b. *Mycobacterium tuberculosis* var. *bovis.*
    3. Experimentally produces generalized tuberculosis in fowls and rabbits but not in guinea pigs.
      2. *Mycobacterium avium.*
  B. Grows in primary culture on glycerol agar only when extracts of, or heat-killed acid-fast bacilli are added. Experimentally fails to infect guinea pigs or fowls.
      3. *Mycobacterium paratuberculosis.*
  C. Have not been grown on culture media thus far devised. Experimentally fail to infect guinea pigs or fowls.
    1. Has not experimentally been transmitted to any animal species.
      4. *Mycobacterium leprae.*
    2. Occurs in wild rats, and can be experimentally transmitted to rats and some strains of mice.
      5. *Mycobacterium lepraemurium.*

---

† Most acid-fast bacteria treated with carbol-auramin and decolorized with NaCl-HCl-alcohol show fluorescence under the microscope when they are radiated by long wavelength ultraviolet light (Haitinger, Fluorescenz-mikroskopie, Leipzig, 1938, 108 pp.; Ellinger, Biol. Revs., *15*, 1940, 323–350; Richards, Jour. Bact., *44*, 1942, 721).

For a discussion of the influence of environment on acid-fastness, see Salle and Moser, Internat. Jour. Leprosy, *5*, 1937, 163.

II. Saprophytes or parasites on cold-blooded animals; grow rapidly on most media.
  A. Fail to survive 60°C for 1 hour.
    1. Fail to grow at 47°C.
      a. Unable to utilize sorbitol.
        6. *Mycobacterium piscium.*
        7. *Mycobacterium marinum.*
        8. *Mycobacterium ranae.*
        9. *Mycobacterium thamnopheos.*
      aa. Utilize sorbitol.
        10. *Mycobacterium friedmannii.*
        11. *Mycobacterium spp.*
    2. Grows at 47°C.
        12. *Mycobacterium lacticola.*
  B. Survives 60°C for 1 hour; grows at 47°C.
        13. *Mycobacterium phlei.*

1. **Mycobacterium tuberculosis** (Schroeter) Lehmann and Neumann. (Tuberkelbacillen, Koch, Mitteil. a.d. kaiserlich. Gesundheitsamte, *2*, 1884, 6; *Bacillus tuberculosis* Schroeter, in Cohn, Kryptogamen Flora v. Schlesien, *3*, 1886, 164; *Bacillus tuberculosis* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 208; *Coccothrix tuberculosis* Lutz, Dermatol. Studien, *1*, 1886, 22; *Sclerothrix kochii* Metchnikoff, Arch. f. path. Anat. u. Physiol., *113*, 1888, 70; *Bacterium tuberculosis* Migula, in Engler and Prantl, Die natürlichen Pflanzenfamilien, I Abt., 1a, 1895, 23; Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 363; *Bacillus kochii*, quoted from Lehmann and Neumann, *idem; Discomyces tuberculosus* (sic), quoted from Neveu-Lemaire, Précis de Parasitol. Humaine, 5th ed., 1921, 25; *Sclerothrix tuberculosis* Vuillemin, Encyclopédie Mycologique, Paris, *2*, 1931, 134; *Eumyces tuberculosis* Battaglia, Soc. Internaz. Microbiol. Boll. Sez. Ital., *10*, 1938, 166.) From M. L. *tuberculosis*, tuberculosis.

Two varieties of this species are commonly recognized, the human and the bovine.

1a. *Mycobacterium tuberculosis* var. *hominis* Lehmann and Neumann. (Human tubercle bacilli, Th. Smith, Trans. Assoc. Am. Phys., *11*, 1896, 75; *Mycobacterium tuberculosis* typus *humanus* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 550.) From Latin *hominis*, of man.

Common name: Human tubercle bacillus.

Description from Koch (*loc. cit.*) and Topley and Wilson (Princip. of Bact. and Immun., London, 2nd ed., 1936, 315).

Rods, ranging in size from 0.3 to 0.6 by 0.5 to 4.0 microns, straight or slightly curved, occurring singly and in occasional threads. Sometimes swollen, clavate or even branched. Stain uniformly or irregularly, showing banded or beaded forms. Acid-fast and acid-alcohol-fast. Gram-positive. Growth in all media is slow, requiring several weeks for development.

This bacterium contains mycolic acid (Stodola, Lesuk, and Anderson, Jour. Biol. Chem., *126*, 1938, 505–513). The acid-fast mycolic acid combines more firmly with carbol-auramin than with carbol-fuchsin and this apparently accounts for the increased sensitivity of fluorescence microscopy for this bacterium (Richards, Science, *93*, 1941, 190; Richards, Kline, and Leach, Amer. Rev. Tuberc., *44*, 1941, 255–266).

Nutrient agar: No growth.

Glycerol agar colonies: Raised, thick, cream-colored, with a nodular or wrinkled surface and irregular thin margin.

Glycerol agar slant: After 4 weeks, raised, thick, confluent, cream-colored growth.

Nutrient broth: No growth.

Glycerol broth: After 8 weeks, thick, white or cream-colored, wrinkled pellicle extending up the sides of the flask, no turbidity; granular or scaly deposit.

Dorset's egg slants: After 4 weeks, rather sparse, discrete or confluent, slightly raised, grayish-yellow growth with finely granular surface.

Glycerol egg slants: After 4 weeks, luxuriant, raised, confluent, gray to yellow growth, with granular surface, generally with nodular heaped-up areas.

Coagulated beef serum: After 4 weeks, thin, effuse, confluent, gray to yellow growth, with a very fine granular surface.

Glycerol beef serum: After 4 weeks, luxuriant, thick, raised, confluent, yellow to orange-yellow growth, with coarsely granular surface, generally with irregularly heaped-up areas.

Litmus milk: Growth, but no change in the milk.

Glycerol potato: After 4 weeks, luxuriant, raised, confluent, cream-colored growth with a nodular or warty surface.

Carbohydrates: Glucose, fructose, arabinose and galactose are utilized; sucrose and lactose not utilized (Merrill, Jour. Bact., *20*, 1930, 235, based on the examination of one strain).

Optimum temperature 37°C.

Optimum pH 7.4 to 8.0 (Ishimori, Ztschr. f. Hyg., *102*, 1924, 329); pH 6.0 to 6.5 (Dernby and Näslund, Biochem. Zeit., *132*, 1922, 392).

Pathogenicity: Produces tuberculosis in man, monkey, dog and parrot. Experimentally, it is highly pathogenic for guinea pigs but not for rabbits, cats, goats, oxen or domestic fowls.

Intermediate mammalian types: Griffith (Lancet, *1*, 1916–17, 721; Jour. Path. and Bact., *21*, 1924, 54) has found aberrant types particularly in skin lesions of both man and ox, which are in certain characteristics intermediate between the human and the bovine varieties. He finds no evidence, however, that the one variety may change into the other.

Variation: Variation in colony structure of the two mammalian varieties, comparable with that in other species, has been described by several authors, as Petroff et al. (Jour. Exp. Med., *60*, 1934, 515), Birkhaug (Ann. Inst. Past., *57*, 1933, 428), Kahn et al. (Jour. Bact., *25*, 1933, 157), Uhlenhuth and Sieffert (Zeit. Immun., *59*, 1930, 187), Reed and Rice (Canad. Jour. Res., *5*, 1931, 111), Smithburn (Jour. Exp. Med., *63*, 1936, 95) and Shaffer (Jour. Path. and Bact., *40*, 1935, 107). Several of these authors have found associated variation in cell structure and in virulence though Boquet (Compt. rend. Soc. Biol. Paris, *103*, 1930, 290), Birkhaug (Ann. Inst. Past., *49*, 1932, 630), and others, have failed to find differences in virulence. Reed and Rice (Jour. Immunol., *23*, 1932, 385) found the S form to contain an antigenic substance lacking in the R form.

Antigenic structure: By agglutination, absorption of agglutinins and complement fixation a distinction may be made between the mammalian varieties and *Mycobacterium avium*, but it has been impossible to distinguish, by these means, between the two mammalian varieties (Tullock et al., Tubercle, *6*, Oct.–Dec., 1924, 18, 57 and 105; Wilson, Jour. Path. and Bact., *28*, 1925, 69; Griffith, Tubercle, *6*, May, 1925, 417; Rice and Reed, Jour. Immunol., *23*, 1932, 385; Kauffman, Ztschr. f. Hyg., *114*, 1932, 121). Tuberculins prepared from the human and the bovine varieties are ordinarily indistinguishable in their action but Lewis and Seibert (Jour. Immunol., *20*, 1931, 201) detected a difference by cross anaphylactic reactions.

Distinctive characters: Tubercle bacilli pathogenic for guinea pigs and rabbits, not for fowls. *Mycobacterium tuberculosis* var. *hominis* produces generalized tuberculosis in guinea pigs but not in rabbits. *Mycobacterium tuberculosis* var. *bovis* produces generalized disease in both guinea pigs and rabbits. Growth of the human variety is enhanced by the addition of glycerol to most media. The growth of the bovine variety is not enhanced by the addition

of glycerol. The human variety generally develops yellow to red pigment on serum media, while the bovine variety never produces pigment. Antigenically the two varieties are not distinguishable.

Source: From tuberculous lesions in man.

Habitat: The cause of tuberculosis in man. Transmissible to rabbits and guinea pigs.

1b. *Mycobacterium tuberculosis* var. *bovis* Lehmann and Neumann. (Bovine tubercle bacilli, Th. Smith, Trans. Assoc. Am. Phys., *11*, 1896, 75; *13*, 1898, 417; Jour. Exp. Med., *3*, 1898, 451; *Mycobacterium tuberculosis* typus *bovinus* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 550.) From Latin *bovis*, of the ox.

Common name: Bovine tubercle bacillus.

Description from Th. Smith (*loc. cit.*) and Topley and Wilson (Princip. of Bact. and Immun., 2nd ed., 1936, 315).

Rods which are shorter and plumper than the human type. Range in size from 1.0 to 1.5 microns. Very short forms are frequently intermixed with somewhat larger forms. Stain regularly or irregularly. Acid-fast and acid-alcohol-fast. Gram-positive. Less easily cultivated than the human variety.

Nutrient agar: No growth.

Glycerol agar colonies: Small, irregular, with granular surface, no pigment.

Glycerol agar slant: After 4 weeks, thin, granular or effuse, confluent growth.

Nutrient broth: No growth.

Glycerol broth: After 8 weeks, thin grayish-white film, slightly nodular, no turbidity. Slight granular deposit.

Dorset's egg slants: After 4 weeks, similar to var. *hominis* but generally poorer growth and no pigmentation.

Glycerol egg slants: After 4 weeks, similar to Dorset's egg slants.

Coagulated beef serum: After 4 weeks, thin, effuse, confluent, white to gray growth with very fine granular surface. Generally less luxuriant than in the human variety.

Glycerol beef serum: After 4 weeks, similar to plain beef serum.

Glycerol potato: After 4 weeks, thin, effuse, grayish growth.

Litmus milk: Growth, but no change in the milk.

Optimum temperature 37°C.

Optimum pH 5.8 to 6.9 (Ishimori, Ztschr. f. Hyg., *102*, 1924, 329); 6.0 to 6.5 (Dernby and Näslund, Biochem. Zeit., *132*, 1922, 392).

Pathogenicity: Produces tuberculosis in ox, man, monkey, goat, sheep, pig, cat, parrot, cockatoo and possibly some birds of prey. Experimentally, it is highly pathogenic for rabbit and guinea pig, slightly pathogenic for dog, horse, rat and mouse; not pathogenic for fowls.

Variation: See *Mycobacterium tuberculosis* var. *hominis*.

Antigenic structure: See *Mycobacterium tuberculosis* var. *hominis*.

Distinctive characters: See *Mycobacterium tuberculosis* var. *hominis*.

Source: From tubercles in cattle.

Habitat: The cause of tuberculosis in cattle. Transmissible to man and domestic animals. More highly pathogenic for animals than the human type.

2. **Mycobacterium avium** Chester. (Tuberculose des oiseaux, Strauss and Gamaléia, Arch. Méd. exp. et Anat. path., 1891; Bacillus der Hühnertuberculose, Maffucci, Ztschr. f. Hygiene, *11*, 1892, 449; *Bacillus tuberculosis gallinarum* Sternberg, Man. of Bact., 1893, 392; *Mycobacterium tuberculosis avium* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *1*, 1896, 370; *Bacillus tuberculosis avium* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 506; *Mycobacterium avium* Chester, Manual Determ. Bact., 1901, 357; *Mycobacterium tuberculosis* typus *gallinaceus* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 553.) From Latin *avis*, bird.

Common name: Avian tubercle bacillus.

Description from Strauss and Gamaléia (*loc. cit.*) and Topley and Wilson (Princip. of Bact. and Immun., 2nd ed., 1936, 315).

Rods resembling those of the bovine type of tubercle organism.

Nutrient agar: After 4 weeks, slight growth, effuse, translucent with fine granular surface.

Glycerol agar colonies: After 3 to 4 weeks, raised, regular, hemispherical, creamy or white colonies.

Nutrient broth: After 4 weeks, very slight viscous to granular bottom growth, no pellicle, no turbidity.

Glycerol broth: After 4 weeks, diffuse, turbid growth with a viscous to granular deposit.

Dorset's egg slants: After 4 weeks, confluent, slightly raised growth, with smooth regular surface.

Glycerol egg slants: After 4 weeks, luxuriant, raised, confluent, creamy to yellow growth with perfectly smooth surface.

Coagulated beef serum: After 4 weeks, thin, effuse, grayish-yellow growth with smooth surface.

Glycerol beef serum: After 4 weeks, luxuriant, raised, confluent, yellow to orange-yellow or occasionally pale pink growth, with a smooth glistening surface.

Glycerol potato: After 4 weeks, luxuriant, raised, confluent, with smooth to nodular surface.

Litmus milk: Growth, but no change in the milk.

Carbohydrates: Fructose, arabinose and sucrose are utilized, glucose is slightly utilized, galactose and lactose are not utilized (Merrill, Jour. Bact., *20*, 1930, 235, based on the examination of one strain).

Optimum temperature 40°C; range 30° to 44°C (Bynoe, Thesis, McGill University, Montreal, 1931).

Optimum pH 6.8 to 7.3 (Bynoe, *loc. cit.*).

Pathogenicity: Produces tuberculosis in domestic fowls and other birds. In pigs it produces localized and sometimes disseminated disease. Experimentally in the rabbit, guinea pig, rat and mouse it may proliferate without producing macroscopic tubercles—tuberculosis of the Yersin type. Man, ox, goat, cat, horse, dog and monkey are not infected.

Variation: Winn and Petroff (Jour. Exp. Med., *57*, 1933, 239), Kahn and Schwartzkopf (Jour. Bact., *25*, 1933, 157), Birkhaug (Ann. Inst. Pasteur, *54*, 1935, 19), Reed and Rice (Canad. Jour. Res., *5*, 1931, 111) and others, have shown variation to follow the course described for many species. Winn and Petroff have separated four colonial types: smooth, flat smooth, rough, deep yellow smooth. These also differ in chemical and physical properties. The smooth form exhibited the greatest degree of virulence, the flat smooth a lower virulence, while the chromogenic smooth and the rough were relatively benign. Some authors have failed to demonstrate this difference in virulence. The above description applies primarily to the smooth form.

Antigenic structure: By agglutination, absorption of agglutinins and complement fixation *Mycobacterium avium* may be distinguished from other members of the genus (Tullock et al., Tubercle, *6*, 1924, 18, 57 and 105; Wilson, Jour. Path. and Bact., *28*, 1925, 69; Mudd, Proc. Soc. Exp. Biol. and Med., *23*, 1925, 569, and others). Furth (Jour. Immunol., *12*, 1926, 273) and Shaffer (Jour. Path. and Bact., *40*, 1935, 107) on this basis divided *Mycobacterium avium* into 1 or 2 subgroups.

Distinctive characters: Tubercle bacilli pathogenic for fowls, not for guinea pigs or rabbits. Culturally distinguished from the mammalian types by the absence of pellicle formation in fluid media and the habit of growth on most solid media. Antigenically distinguished from other species.

Source: From tubercles in fowls, widely distributed as the causal agent of tuberculosis in birds and less frequently in pigs.

Habitat: The cause of tuberculosis in chickens. Transmissible to pigeon, other birds, mouse, rabbit and pig.

3. **Mycobacterium paratuberculosis** Bergey et al. (Darmtuberculose bacillen, Johne and Frothingham, Deutsch. Ztschr. Tiermed., *21*, 1895, 438; Pseudotuberkulose bacillen, Bang, Berl. tierärztl. Wchnschr., 1906, 759; Bacillus of Johne's Disease, M'Fadyean, Jour. Comp. Path., *20*, 1907, 48; Twort, Proc. Roy. Soc., B, *83*, 1910, 156; Bergey et al., Manual, 1st ed., 1923, 374.) From M. L. *paratuberculosis*, of the disease paratuberculosis.

Common name: Johne's bacillus.

The organism from a similar disease in sheep is probably identical though more difficult to cultivate (Dunkin and Balfour-Jones, Jour. Comp. Path., *48*, 1935, 236).

Description from M'Fadyean (*loc. cit.*) and Twort and Ingram (A Monograph on Johne's Disease, London, 1913).

Plump rods, 1.0 to 2.0 microns in length, staining uniformly, but occasionally the longer forms show alternately stained and unstained segments. Non-motile. Acid-fast.

The organism is difficult to cultivate and, in primary cultures, has only been grown in media containing dead tubercle bacilli or other dead acid-fast bacteria (Boquet, Ann. Inst. Pasteur, *37*, 1928, 495). In a few instances cultures have been acclimatized to a synthetic medium free from added dead bacteria (Dunkin, Jour. Comp. Path. and Therap., *46*, 1933, 159; Watson, Canad. Pub. Health Jour., *26*, 1935, 268).

Colonies on glycerol agar containing heat-killed *Mycobacterium phlei:* After 4 to 6 weeks, just distinguishable, dull-white, raised, circular colonies.

Colonies on Dorset's glycerol egg containing heat-killed *Mycobacterium phlei:* After 4 to 6 weeks, minute, dull-white, raised, circular, with a thin, slightly irregular margin. Older colonies become more raised, radially striated or irregularly folded and dull yellowish-white.

Dorset's glycerol egg containing sheep's brain and heat-killed *Mycobacterium phlei:* Growth slightly more luxuriant.

Glycerol broth containing heat-killed *Mycobacterium phlei:* Thin surface pellicle which later becomes thickened and folded.

Dorset's synthetic fluid containing heat-killed *Mycobacterium phlei:* As on glycerol broth with *Mycobacterium phlei.*

Pathogenicity: Produces Johne's disease, chronic diarrhea, in cattle and sheep. Experimentally it produces a similar disease in bovine animals, sheep and goats. Guinea pigs, rabbits, rats and mice are not infected. Very large doses in laboratory animals produce slight nodular lesions comparable with those produced by *Mycobacterium phlei.*

Antigenic structure: Johnin, prepared as tuberculin, gives positive reactions in cattle with Johne's disease. According to M'Fadyean et al. (Jour. Comp. Path. and Therap., *29*, 1916, 62) tuberculous animals may also give a reaction. Plumb (Den Kong. Vet. Landbohøjskole Årssk., 1925, 63) has shown that a reaction may be produced in animals sensitized to avian tuberculin and that avian tuberculin causes a reaction in some animals infected with Johne's bacillus.

Distinctive characters: A small acid-fast bacillus producing characteristic lesions in cattle and growing only in the presence of dead acid-fast bacilli.

Source: From the intestinal mucous membrane of cattle suffering from chronic diarrhea. Apparently an obligate parasite.

Habitat: The cause of Johne's disease, a chronic diarrhea in cattle. The bacteria are found in the intestinal mucosa. Not pathogenic for guinea pigs or rabbits.

4. **Mycobacterium leprae** (Armauer-Hansen) Lehmann and Neumann. (*Bacillus leprae* Armauer-Hansen, Norsk. Mag. Laegevidensk., *9*, 1874, 1; Arch. f. path. Anat. u. Physiol., *79*, 1879,

32; Nord. Med. Ark., *12*, 1880, 1; Quart. Jour. Micro. Sci., *20*, 1880, 92; *Coccothrix leprae* Lutz, Dermatol. Stud. *1*, 1886, quoted from DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 944; Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 372; *Discomyces leprae* Neveu-Lemaire, Précis Parasit. Hum., 5th ed., 1921, 27; *Sclerothrix leprae* Vuillemin, Encyclopédie Mycologique, Paris, *1*, 1921, 135; *Mycobacterium leprae hominus* Lowe, Internat. Jour. Leprosy, *5*, 1937, 312.) From Greek *lepra*, leprosy.

Common name: Leprosy bacillus.

Armauer-Hansen (*loc. cit.*) was the first to observe the bacilli in the tissues of lepers. The disease is now known as Hansen's disease. The bacilli occur in enormous numbers in lepromatous (nodular) cases of the disease and sparsely in the neural form. The present bacteriological means of identification depend on: (a) acid-fast staining, and (b) failure of the organism to grow in bacteriological media or in laboratory animals. Heated suspensions of the bacilli (obtained from nodules) produce a positive lepromin reaction in 75 to 97 per cent of normal persons and of neural cases of leprosy, but usually produce no reaction in lepromatous individuals (Mitsuda: See Hayashi, Int. Jour. Leprosy, *1*, 1933, 31–38). The failure of lepromatous persons to respond to injected leprosy bacilli constitutes a fundamental criterion for testing the validity of microorganisms such as other acid-fast or diphtheroid cultures which can at times be recovered from leprous tissues by inoculation of bacteriological media.

Many organisms have been isolated from leprous tissues, some of which are acid-fast and have been styled *Mycobacterium leprae*. The strains which have been adequately studied have proven to fall into the saprophytic groups (see No. 11, *Mycobacterium spp.*) Hanks (Int. Jour. Leprosy, *9*, 1941, 275–298) found that acid-fast cultures of this type, as well as the diphtheroids which also have repeatedly been isolated from leprosy, were recoverable only from lesions located proximally with respect to open ulcers in the skin.

Description of organisms seen in leprosy tissue from Armauer-Hansen (*loc. cit.*) and Topley and Wilson (Princip. Bact. and Immun., 2nd ed., 1936, 316).

Rods: 0.3 to 0.5 by 1 to 8 microns, with parallel sides and rounded ends, staining evenly or at times beaded. When numerous, as from lepromatous cases, they are generally arranged in clumps, rounded masses or in groups of bacilli side by side. Strongly acid-fast. Gram-positive.

Pathogenicity: The communicability of leprosy from man to man is accepted (Rogers and Muir, Leprosy, 2nd ed., Baltimore, 1940, 260 pp.). Experimental transmission to humans or to animals has not been successful.

Source: Human leprous lesions. In the lepromatous form of the disease bacilli are so abundant as to produce stuffed-cell granulomas; in the tuberculoid and neutral lesions they are rare.

Habitat: Obligate parasite in man. Confined largely to the skin (especially to convex and exposed surfaces) and to peripheral nerves. The microorganisms probably do not grow in the internal organs.

5. **Mycobacteriun lepraemurium** Marchoux and Sorel. (Bacillus der Rattenlepra, Stefansky, Cent. f. Bakt., I Abt., Orig., *33*, 1903, 481; *Mycobacterium leprae murium* Marchoux and Sorel, Ann. Inst. Past., *26*, 1912, 700; *Bacillus leprae murium* Muir and Henderson, Indian Jour. Med. Res., *15*, 1927, 15.)

Mycobacterium pulviforme Marchoux (Ann. Derm., 1921, No. 21 and Ann. Inst. Past., *37*, 1923, 348) from leprosy-like lesions in a man from Hayti is thought by the author to be identical with *Mycobacterium lepraemurium*.

Common name: Rat leprosy bacillus.

Rods: 3.0 to 5.0 microns in length with slightly rounded ends. When stained, often show irregular appearance. Strongly acid-fast. Gram-positive.

Like the human leprosy bacillus, this organism has not been cultivated in vitro; but can be passed experimentally through rats and some strains of mice.

Distinctive features: The heat-killed bacilli produce lepromin reactions in lepratomous humans. The bacilli from lesions are not bound together in clumps, rounded masses and palisades as in human lesions. For further details see review by Lowe (Internat. Jour. Leprosy, *5*, 1937, 310 and 463).

Source: An endemic disease of rats in various parts of the world, having been found in Odessa, Berlin, London, New South Wales, Hawaii, San Francisco and elsewhere.

Habitat: The natural disease occurs chiefly in the skin and lymph nodes, causing induration, alopecia (loss of hair) and eventually ulceration.

6. **Mycobacterium piscium** Bergey et al. (*Bacillus tuberculosis piscium* Dubard, Bull. acad. de méd., 3 sér., *38*, 1897, 580; Bataillon, Dubard and Terre, Compt. rend. Soc. Biol., *4*, sér. 10, 1897, 446; Bergey et al., Manual, 1st ed., 1923, 375.) From Latin *piscis*, fish.

Description from Bataillon et al. (*loc. cit.*) and Aronson (Jour. Inf. Dis., *39*, 1926, 319).

Slender rods, occurring singly and in threads, occasionally showing branching. Acid-fast. Non-motile. Gram-positive.

Agar colonies: Small, circular, white, moist, with lobate margin and fine granular surface.

Agar slant: Scant, white, moist, cream-like.

Glycerol agar colonies: Thin, flat, smooth, glistening, yellow.

Dorset's egg medium: Flat, smooth, moist, greenish.

Broth: Thin pellicle, with flocculent sediment.

Litmus milk: Thickened. No coagulation. Slightly alkaline.

Potato: White, warty, butyrous colonies.

Carbohydrates: Utilizes glucose and fructose but not sucrose, lactose, arabinose or galactose (Merrill, Jour. Bact., *20*, 1930, 235, based on examination of one strain).

Antigenic structure: By agglutination and complement fixation (Mudd, Proc. Exp. Biol. and Med., *23*, 1925, 569; and Furth, Jour. Immunol., *12*, 1926, 286) *Mycobacterium piscium* has been distinguished from *Mycobacterium friedmannii*, *Mycobacterium ranae* and probably *Mycobacterium marinum*. From the limited number of cultures examined it is not evident whether this is due to species or strain specificity.

Pathogenicity: Experimentally produces tubercles in carp, frog and lizard, but not pathogenic for rabbit, guinea pig or birds (Dubard, Rev. de la Tuberc., *6*, 1898, 13). Not pathogenic for salt water fish except eels (Betegh, Cent. f. Bakt., I Abt., Orig., *53*, 1910, 374; *54*, 1910, 211).

Distinctive characters: *Mycobacterium piscium*, *Mycobacterium marinum*, *Mycobacterium ranae*, *Mycobacterium thamnopheos* and *Mycobacterium friedmannii* constitute a closely related group—possibly one species. They differ from other members of the genus in their pathogenicity for cold-blooded animals, their failure to survive 60°C for an hour, their failure to grow at 47°C and their inability to utilize sorbitol.

Mycobacterium marinum is distinguished by its diffuse growth in broth, acid production in milk and deep yellow to orange pigmentation on most media. The other species grow in broth as a pellicle and render milk alkaline. *Mycobacterium piscium*, *Mycobacterium ranae*, *Mycobacterium thamnopheos* and *Mycobacterium friedmannii* may be distinguished from each other by their habit of growth on solid media. But relatively few cultures have been studied

and the reports in certain important respects are conflicting, especially concerning pigmentation and utilization of carbohydrates. Aronson, Mudd and Furth found them to differ antigenically, but too few cultures were used to distinguish between species and strain specificity.

Source: From tubercles in carp.

Habitat: The cause of nodule and tumor-like formations in carp (*Ciprinus carpio*). Infectious for carp, frogs, lizards. Not infectious for guinea pigs and pigeons.

7. **Mycobacterium marinum** Aronson. (Jour. Inf. Dis., *39*, 1926, 315.) From Latin *marinus*, marine.

Description from Aronson (*loc. cit.*).

In lesions, short, thick, uniformly staining organisms are seen frequently occurring in clumps, while long, thin, beaded or barred rods are scattered more discretely. In cultures the organisms have the same appearance. Non-motile. Acid-fast and acid-alcohol-fast. Gram-positive.

Agar slant (slightly acid): In five to seven days, moist, glistening, elevated colonies, becoming lemon-yellow.

Gelatin: Not liquefied.

Agar colonies: In 5 to 7 days, smooth, moist, slimy, lemon-yellow, later orange-colored.

Glycerol agar colonies: In 14 to 18 days, grayish-white, moist, elevated with irregular margins. Old growths lemon-yellow and still later orange-colored.

Dorset's and Petroff's egg media: Similar to growth on glycerol agar but more luxuriant.

Broth and glycerol broth: Growth is diffuse, no pellicle formed.

Litmus milk: Acidified and coagulated.

Indole not formed.

Nitrites not produced from nitrates.

Carbohydrates: Utilizes arabinose and fructose, fails to utilize sorbitol and galactose (Gordon, Jour. Bact., *34*, 1937, 617).

Aerobic, facultative.

Optimum temperature 18° to 20°C. Fails to survive 60°C for 1 hour, fails to grow at 47°C (Gordon, Jour. Bact., *34*, 1937, 617).

Pathogenicity: Experimentally infects salt water fish, goldfish, frogs, mice and pigeons, but not rabbits or guinea pigs.

Antigenic structure: By agglutination and complement fixation distinguished from *Mycobacterium ranae*, *Mycobacterium friedmannii*, and probably *Mycobacterium piscium* (Mudd, Proc. Soc. Exp. Biol. and Med., *23*, 1925, 569; Furth, Jour. Immunol., *12*, 1926, 286). See *Mycobacterium piscium*.

Distinctive characters: See *Mycobacterium piscium*.

Source: From areas of focal necrosis of the liver of sergeant majors (*Abudefduf mauritii*), croakers (*Micropogon undulatus*) and sea bass (*Centropristes striatus*).

Habitat: Causes spontaneous tuberculosis in salt water fish.

8. **Mycobacterium ranae** (Küster) Bergey et al. (Küster, Münch. med. Wchnschr., *52*, 1905, 57; Bergey et al., Manual, 1st ed., 1923, 374.) From Latin *rana*, frog.

Description from Küster (*loc. cit.*), Bynoe (Thesis, McGill University, Montreal, 1931) and Aronson (Jour. Inf. Dis., *44*, 1929, 222).

Slender rods, 0.3 to 0.5 by 2 to 8 microns, smaller in old cultures. Uniformly acid-fast in cultures 2 weeks old or older. In younger cultures the staining is irregular, many organisms are not acid-fast. Non-motile. Gram-positive.

Gelatin stab: No liquefaction.

Agar colonies: Irregular, raised colonies, 1 to 3 mm in diameter with moist glistening surface, later becoming coarsely granular.

Agar slant: Thick, spreading, glistening. In old cultures dry and scaly. Putrid odor. Grayish-white.

Glycerol agar colonies: Similar to gelatin colonies but slightly creamy and becoming dry and wrinkled in old cultures.

Dorset's egg medium: Spreading, raised, glistening, later wrinkled.

Loeffler's medium: Similar to Dorset's egg medium, white to buff-colored.

Litmus milk: Becomes alkaline.

Glycerol broth: Grayish flaky pellicle which breaks up early and settles.

Broth: Slightly turbid; with slight sediment.

Potato: Scanty, grayish growth, raised with a warty surface.

Indole not formed.

Nitrites are produced from nitrates.

Carbohydrates: Glucose, fructose and arabinose are utilized; sucrose, lactose and galactose not utilized (Merrill, Jour. Bact., *20*, 1930, 235). Fructose, mannitol and trehalose are utilized; sorbitol, arabinose and galactose are not utilized (Gordon, Jour. Bact., *34*, 1937, 617).

No H_2S formed.

Optimum temperature 28°C (Küster), 37°C (Bynoe).

Optimum pH 6.6 to 7.3, range 4.0 to 10.0.

Antigenic structure: By agglutination and complement fixation *Mycobacterium ranae* may be distinguished from *Mycobacterium piscium* and *Mycobacterium friedmannii* (Mudd, Proc. Soc. Exp. Biol. and Med., *23*, 1925, 569; Furth, Jour. Immunol., *12*, 1926, 286). See *Mycobacterium piscium*.

Pathogenicity: Experimentally causes tuberculosis in frogs, lizards, turtles; not pathogenic for rabbits, guinea pigs, rats or mice.

Distinctive characters: See *Mycobacterium piscium*.

Source: From the liver of a frog.

Habitat: In a group of 215 cultures belonging to the genus, isolated from soils, Gordon (Jour. Bact., *34*, 1937, 617) found 65 to sufficiently resemble *Mycobacterium ranae* to indicate at least a very close relationship. If they prove to be identical, the species is widely distributed.

9. **Mycobacterium thamnopheos** Aronson. (Jour. Inf. Dis., *44*, 1929, 222.) From *Thamnophis*, a genus of snakes.

Tuberculbacillen bei Schlangen, Sibley, Arch. f. pathol. Anat. u. Physiol., *116*, 1889, 104 (*Mycobacterium tropidonatum* (sic) Bergey et al., Manual, 1st ed., 1923, 376) is probably identical, but the descriptions are too meager to be conclusive. Acid-fast bacilli described by Gibbes and Shurley (Amer. Jour. Med. Sci., *100*, 1890, 145) as the cause of tuberculosis in boas and pythons; by Shattock (Trans. Path. Soc., London, *53*, 1902, 430) and by von Hanseneann (Cent. f. Bakt., I Abt., Orig., *34*, 1903, 212) as causing tuberculosis in a *Python molurus*, are possibly identical, but the descriptions do not permit us to draw any conclusions. According to Aronson, similar organisms isolated from pathological lesions in boa constrictors and *Caluber catenifer* differ antigenically from *Mycobacterium thamnopheos*.

Description taken from Aronson (*loc. cit.*) and Bynoe (Thesis, McGill University, Montreal, 1931).

Slender rods: 0.5 by 4 to 7 microns, frequently slightly curved, beaded and barred forms frequently occur. Non-motile. Acid-fast in cultures of 4 days or older, in younger cultures some organisms are not acid-fast. Not alcohol-fast. Gram-positive.

Gelatin stab: Growth occurs along the line of inoculation. No liquefaction.

Agar colonies: 0.5 to 1 mm in diameter, irregular, raised, moist and glistening.

Glycerol agar: Spreading, raised, dry, pale pink to buff growth.

Glycerol broth: A thin pellicle appears in 5 to 6 days, gradually becomes thicker and falls as a sediment.

Dorset's egg medium: Raised, moist, pinkish growth after 10 days, later becoming salmon-colored.

Loeffler's serum: Small, raised, convex, dry growth.

Litmus milk: Alkaline.

Glycerol potato: Raised, hemispherical, dry and granular growth.

Indole not produced.

Nitrates: Not reduced by 2 strains,

reduced by 1 strain (Aronson); slightly reduced (Gordon); not reduced (Bynoe).

Carbohydrates: Utilizes fructose, mannitol and trehalose; fails to utilize arabinose, sucrose, galactose and sorbitol (Gordon, Jour. Bact., *34*, 1937, 617).

Temperature relations: Fails to survive 60°C for 1 hour, fails to grow at 47°C (Gordon); good growth at 25°C, no growth at 37°C (Aronson); optimum for growth 25°C, range 10° to 35°C (Bynoe).

Range of pH: 6.6 to 7.8 (Aronson); optimum 7.3 to 8.0, range 5.0 to 11.0 (Bynoe).

Pathogenicity: Experimentally produces generalized tuberculosis in snakes, frogs, lizards and fish but not pathogenic for guinea pigs, rabbits or fowls.

Antigenic structure: By agglutination and absorption of agglutinins *Mycobacterium thamnopheos* may be distinguished from *Mycobacterium marinum*, *Mycobacterium friedmannii* and *Mycobacterium ranae*. See *Mycobacterium piscium*.

Variation: According to Bynoe and Wyckoff (Amer. Rev. Tub., *29*, 1934, 389) S and R forms may be distinguished by colony structure and individual cell arrangement.

Distinctive characters: See *Mycobacterium piscium*.

Source: From the lungs and livers of garter snakes (*Thamnophis sirtalis*).

Habitat: Present as a parasite in the garter snake and possibly other cold-blooded vertebrates.

10. **Mycobacterium friedmannii** Holland. (Schildkröten tuberkelbacillus, Friedmann, Cent. f. Bakt., I Abt., Orig., *34*, 1903, 647; *Bacillus friedmanii* (*sic*) Holland, Jour. Bact., *5*, 1920, 218; *Mycobacterium friedmanii* Holland, *ibid.*; *Mycobacterium chelonei* Bergey et al., Manual, 1st ed., 1923, 376.) Named for Dr. Friedmann, who isolated this organism.

Common name: Turtle bacillus.

Description from Friedmann (*loc. cit.*) and Aronson (Jour. Inf. Dis., *44*, 1929, 222).

Slender rods: 0.2 to 0.4 by 0.5 to 5 microns. Beaded forms are common. Acid-alcohol-fast in young cultures but in cultures two weeks old generally there are many non-acid-fast rods. Non-motile. Gram-positive.

Gelatin stab: White surface growth, scanty growth along the line of stab. No liquefaction.

Agar colonies: 1 to 3 mm in diameter, irregularly round, raised, moist, glistening, white.

Glycerol agar slants: Thick, spreading growth, at first moist, later granular, yellowish-white (Friedmann); olive-gray (Bynoe); white (Aronson).

Glycerol broth: Thick wrinkled pellicle after two to three days growth, later some membranous sediment. Grayish-yellow (Friedmann); grayish-white (Bynoe).

Dorset's egg medium: Spreading, raised, slightly moist, pale buff.

Loeffler's serum: Scant growth, raised, dry, crumb-like.

Litmus milk: Slightly alkaline after 10 days growth.

Glycerol potato: Thick, wrinkled, gray after 2 days growth.

Indole not formed.

Carbohydrates: Glucose, fructose and arabinose utilized, sucrose slightly utilized, galactose and lactose not utilized (Merrill, Jour. Bact., *20*, 1930, 235). Arabinose not utilized (Gordon, Jour. Bact., *34*, 1937, 617).

Optimum temperature 25° to 30°C.

Pathogenicity: Experimentally produces tubercles in most species of cold-blooded animals, possibly in guinea pigs but not in other warm-blooded animals.

Variation: According to Gildemeister (Cent. f. Bakt., I Abt., Orig., *86*, 1921, 513) S and R types may be distinguished on glycerol agar. The S grows as smooth, moist, glistening, convex colonies; the R as flat, dry, spreading colonies. Wykoff (Amer. Rev. Tub., *29*, 1934, 289) has shown a difference in the form of cell division and corresponding cell arrangement of the two types.

Distinctive characters: See *Mycobacterium piscium*.

Source: From the lungs of turtles in the Berlin aquarium.

Habitat: A parasite in turtles and possibly sparingly distributed in soils. Gordon (Jour. Bact., *34*, 1937, 617) found 65 out of 215 soil cultures of members of the genus to closely resemble this species.

11. **Mycobacterium spp.** (A miscellaneous group many of which have been incorrectly identified as *Mycobacterium leprae* Lehmann and Neumann.)

Clegg (Phil. Jour. Sci., *4*, 1909, 77 and 403), Duval (Jour. Exp. Med., *12*, 1910, 649), Duval and Wellman (Jour. Inf. Dis., *11*, 1912, 116), Currie, Brinckerhoff and Hollmann (Pub. Health Rep., *25*, 1910, 1173) and others have described as *Mycobacterium leprae* a group of organisms isolated from leprosy lesions. Much evidence, summarized by McKinley (Medicine, *13*, 1934, 377), points to the conclusion that these organisms are not pathogenic and not the causal agent of leprosy. They cannot therefore be included under *Mycobacterium leprae* as defined above.

Thomson (Amer. Rev. Tub., *26*, 1932, 162), Gordon (Jour. Bact., *34*, 1937, 617), and Gordon and Hagan (Jour. Bact., *36*, 1938, 39) recently separated the saprophytic members of the genus *Mycobacterium* into three main groups and several subgroups. Species names as here defined have been added to the key as follows:

Group I. Fail to survive 60°C for 1 hour. Grow at 47°C.
- a. Utilizes arabinose.
  - *Mycobacterium lacticola.*
- b. Unable to utilize arabinose.
  - *Mycobacterium sp.*

Group II. Fail to survive 60°C for 1 hour. Do not grow at 47°C.
- a. Unable to utilize sorbitol.
  - 1. Unable to utilize arabinose.
    - *Mycobacterium ranae.*
    - *Mycobacterium thamnopheos.*
    - *Mycobacterium sp.*
  - 2. Utilize arabinose.
    - *Mycobacterium marinum.*
    - *Mycobacterium sp.*
- b. Utilizes sorbitol.
  - *Mycobacterium spp.*
- c. Unable to utilize most carbohydrates.
  - *Mycobacterium friedmannii.*
  - *Mycobacterium sp.*

Group III. Survive 60°C for 1 hour. Grow at 47°C.
- a. Utilizes arabinose.
  - *Mycobacterium phlei.*
- b. Unable to utilize arabinose.
  - *Mycobacterium sp.*

In this study Gordon and Hagan included many recently isolated soil forms, named saprophytic species, pathogens for cold-blooded animals and 19 cultures, from various collections, which bore the name *Mycobacterium leprae.* Of these so-called *Mycobacterium leprae*, six belong to Group I which corresponds with *Mycobacterium lacticola* and includes many soil forms, two belong to Group IIa which includes *Mycobacterium ranae*, *Mycobacterium thamnopheos* and a number of undefined soil forms, while eleven belong to Group IIb. The latter group includes a number of soil cultures but no other defined species.

In the several groups to which so-called *Mycobacterium leprae* strains belong, some appear to be indistinguishable from soil forms, others are distinguished by habit of growth, utilization of carbohydrates or by pigmentation.

12. **Mycobacterium lacticola** Lehmann and Neumann. (Bakt. Diag., 2 Aufl., *2*,

1899, 409.) From Latin *lac*, *lactis*, milk and *colo*, to dwell; hence, a milk dweller.

From the fact that Lehmann and Neumann (*loc. cit.*, 411) refer to the binomial *Bacillus friburgensis* Korn, it is evident that the species name *friburgensis* (see Appendix) published the same year (1899) has priority over the species name *lacticola*. However, since it has never been used with the broad meaning given *Mycobacterium lacticola* by Lehmann and Neumann in the original description, it is not substituted for the more commonly used *Mycobacterium lacticola* in this edition of the Manual.

Description from Lehmann and Neumann (*loc. cit*) and Jensen (Proc. Linnean Soc. of New So. Wales, *59*, 1934, 19).

Slender rods: 0.5 to 0.7 by 2 to 8 microns in young cultures, in older cultures the rods are shorter and frequently coccoid in shape. Curved and irregular forms occur occasionally. Branched forms, if they occur, are very rare. Staining is generally uniform but slight beading occurs occasionally. Strongly acid-fast except organisms from glucose-containing media which are sometimes only faintly acid-fast. Gram-positive.

Gelatin colonies: Similar to those on agar.

Gelatin stab: Filiform growth in stab. No liquefaction.

Agar colonies: Convex, glistening, with entire margins, at first smooth but after 10 to 14 days growth folded or wrinkled. Opaque, at first white, after 2 or 3 days growth becomes yellow.

Glucose agar: Similar to agar but more rapid growth and less intensely pigmented.

Glycerol agar slants: Spreading, moist, wrinkled, pale cream-colored to yellow.

Nutrient broth: Diffuse growth, later with yellowish pellicle.

Litmus milk: Small white granules of growth at the surface, later a dry yellowish pellicle. After some weeks' growth the milk becomes alkaline and clear. No coagulation.

Dorset's egg medium: As on glycerol agar.

Coagulated serum: As on glycerol agar.

Potato: Spreading, raised, wrinkled growth, pale yellow to orange.

Long's medium lacking glycerol: No growth. Long's medium with 5 per cent glycerol: Acid formed. (Thomson, Amer. Rev. Tub., *26*, 1932, 162.)

Indole not formed.

Nitrates: Reduced, doubtful (Jensen).

Carbohydrates: Glucose, fructose, arabinose and galactose are utilized; lactose is not utilized; sucrose is not utilized by 3 strains, utilized by 1 strain (*Mycobacterium friburgensis*) (Merrill, Jour. Bact., *20*, 1930, 235). Sorbitol, arabinose, galactose, trehalose, mannitol and fructose are utilized; sucrose is not utilized (Gordon, Jour. Bact., *34*, 1937, 617).

Optimum temperature 37°C, maximum temperature for growth 52°C, minimum 15° to 18°C. Fails to survive 60°C for 1 hour, grows at 47°C (Gordon, Jour. Bact., *34*, 1937, 617; Gordon and Hagan Jour. Bact., *36*, 1938, 39).

Optimum pH 6.8 to 7.2. Limits for growth 4.5 to 10.0.

Distinctive characters: Saprophytic acid-fast organism. Grows rapidly on most media, develops a yellow or orange pigmentation after 3 to 4 days growth. Fails to grow on Long's medium lacking glycerol and produces acid when glycerol is present. Fails to survive 60°C for an hour, grows at temperatures as high as 47°C.

Variation: Lehmann and Neumann (Bakt. Diag., 2 Aufl., *2*, 1899, 408) and Haag (Cent. f. Bakt., II Abt., *71*, 1927, 1) describe three forms: a flat smooth form, a moist, slimy, smooth form and a dry, friable perrugose form. The two former correspond with S and the latter with R types described by Bynoe as characteristic of *Mycobacterium stercoris*, *Mycobacterium berolinensis*, *Mycobacterium butyricum* and *Mycobacterium graminis* which in turn correspond with S and R types of other members of the genus. Schwabacher (Spec. Rep. Ser. Med. Res.

Coun., London, No. 182, 1933) finds a difference in the arrangement of the individual cells of the S and R types.

Source: From butter, plant dust, cow manure.

Habitat: Gordon (Jour. Bact., *34*, 1937, 617) found 1 culture isolated from nasal exudate, 1 from bovine lymph gland and 94 isolated from soil, out of a group of 215 soil cultures belonging to the genus, to be either identical with or very closely related to this species. If these strains are valid members of the species, *Mycobacterium lacticola* is widely distributed in soil, dust, dairy products, etc.

13. **Mycobacterium phlei** Lehmann and Neumann. (Timotheebacillus or Grasbacillus I, Moeller, Therapeutischen Monatsheften, *12*, 1898, 607; Moeller, Deut. med. Wchnschr., *24*, 1898, 376; Lehmann and Neumann, Bakt. Diag., 2 Aufl., *2*, 1899, 411; *Mycobacterium moelleri* Chester, Manual Determ. Bact., 1901, 358; *Sclerothrix phlei* Vuillemin, Encyclopédie Mycologique, Paris, *2*, 1931, 160.) From M. L. *Phleum*, a genus of grasses.

Description from Moeller (*loc. cit.*) and Jensen (Proc. Linnean Soc. New So. Wales, *59*, 1934, 32).

Slender rods: 0.2 to 0.5 by 1 to 4 microns, sometimes club-shaped, frequently beaded, rarely branched. Strongly acid-fast and acid-alcohol-fast in cultures older than 2 to 3 days, in younger cultures there are generally many non-acid-fast cells. Non-motile. Gram-positive.

Gelatin colonies: Small, 0.5 to 1 mm in diameter; irregular, raised, moist and glistening, finely granular, orange.

Gelatin stab: Filiform, opaque, orange. No liquefaction.

Agar colonies: Similar to gelatin colonies, yellow to orange.

Agar slant: Spreading, raised, dry with roughened granular surface, yellow to orange.

Broth: Turbid, with yellow pellicle.

Dorset's egg medium: Spreading, raised, dry, orange.

Loeffler's serum: Similar to Dorset's egg medium, creamy to yellow.

Glycerol broth: Thin transparent pellicle, later becoming thickened, rough, wrinkled and yellow to pink, still later a flaky sediment.

Litmus milk: Yellow flocculi on surface, slowly becomes alkaline. No coagulation.

Potato: Thick, dry, yellow, adherent growth.

Long's medium lacking glycerol: Abundant growth. Long's medium with 5 per cent glycerol: No acid formed (Thomson, Amer. Rev. Tub., *26*, 1932, 162).

Nitrites are produced from nitrates.

Indole not formed.

Carbohydrates: Glucose, fructose, arabinose, trehalose, mannitol and galactose are utilized; sucrose and lactose are not utilized (Merrill, Jour. Bact., *20*, 1930, 235; Gordon, Jour. Bact., *34*, 1937, 617).

Temperature relations: Survives 60°C for 1 hour, grows at 47°C (Thomson, Amer. Jour. Tub., *26*, 1932, 162); optimum for growth 37°C, range 20° to 58°C (Bynoe).

Optimum pH 6.8 to 7.3; range 5.5 to 10.0.

Pathogenicity: The injection of large numbers of organisms into guinea pigs results in a local abscess of a few weeks' duration, occasionally small abscesses develop in the regional lymph glands or the visceral organs. According to Mayer (Cent. f. Bakt., I Abt., *26*, 1899, 331) and others, the injection of the organisms along with butter or other fat increases the pathological reaction.

Variation: Haag (Cent. f. Bakt., II Abt., *71*, 1927, 1) and Bynoe (Thesis, McGill University, Montreal, 1931) find two or three colony types: an R form which fits into the description of the species given above and an S type which grows as a perfectly smooth, raised, moist, glistening colony with an entire margin. Cooper (Jour. Inf. Dis., *54*, 1934, 236) distinguished pigmented and non-pigmented types.

Distinctive characters: Saprophyti acid-fast organism, grows rapidly on most media. Shows yellow pigmentation as soon as growth is visible. Grows well on Long's medium lacking glycerol and fails to produce acid when glycerol is present. Survives 60°C for 1 hour and grows at 47°C.

Source: Originally isolated from hay and grass. Frequently found in soil, dust and other sources. Out of 215 cultures of the genus recovered from soils by Gordon (Jour. Bact., *34*, 1937, 617) *Mycobacterium phlei* was isolated on 22 occasions. The same author reports 3 cultures of a closely related if not identical organism recovered from bovine lymph glands, 1 recovered from bovine skin and 1 recovered from a hen's spleen.

Habitat: Widely distributed in soils, dust, hay, etc.

Appendix I: The following saprophytic species have been placed in this genus. Their relationships are not clear. Some are related to or possibly identical with *Mycobacterium lacticola*.

Mycobacterium album Söhngen. (Cent. f. Bakt., II Abt., *37*, 1913, 599.) From garden earth.

Mycobacterium bekkerii Bekker. (Antonie van Leeuwenhoek, *9*, 1943, 81; abst. in Cent. f. Bakt., I Abt., Orig., *149*, 1944, 500.) From urine.

Mycobacterium berolinense Bergey et al. (Tuberkelähnlichen Bacillen, Rabinowitsch, Ztschr. f. Hyg., *26*, 1897, 90; *Mycobacterium lacticola β perrugosum* Lehmann and Neumann, Bakt. Diag., 2 Aufl., *2*, 1899, 410; *Mycobacterium lacticola perrugosum* Haag, Cent. f. Bakt., II Abt., *71*, 1927, 3; Bergey et al., Manual, 1st ed., 1923, 377.) From butter.

Mycobacterium butyri Chester. (Man. Determ. Bact., 1901, 357.) This name includes both the Tuberkelähnlichen Bacillen of Rabinowitsch and the Butter Bacillus of Petri. From butter.

Mycobacterium butyricum Bergey et al. (Butter Bacillus, Petri, Arb. kaiserl. Gesundheitsamte, *14*, 1898, 1; Bergey et al., Manual, 1st ed., 1923, 377.) From butter.

Mycobacterium cholesterolicum Tak. (Antonie van Leeuwenhoek, *8*, 1942, 39.) From garden soil.

Mycobacterium friburgensis (Korn) Chester. (*Bacillus friburgensis* Korn, Cent. f. Bakt., I Abt., *25*, 1899, 532; *Mycobacterium lacticola γ friburgensis* Lehmann and Neumann, Bakt. Diag., 2 Aufl., *2*, 1899, 411; Chester, Man. Determ. Bact., 1901, 359.) From butter.

Mycobacterium graminis Chester. (Grasbacillus II, Moeller, Cent f. Bakt., I Abt., *25*, 1899, 369; *Mycobacterium lacticola α planum* Lehmann and Neumann, Bakt. Diag., 2 Aufl., *2*, 1899, 408; Chester, Man. Determ. Bact., 1901, 358; *Mycobacterium lacticola planum* Haag, Cent. f. Bakt., II Abt., *71*, 1927, 3.) From hay dust.

Mycobacterium hyalinum Söhngen. (Cent. f. Bakt., II Abt., *37*, 1913, 599.) From garden earth.

Mycobacterium luteum Söhngen (*loc. cit.*). From garden earth.

Mycobacterium muris Simmons. (Jour. Inf. Dis., *41*, 1927, 13.) From the feces of gray mice.

Mycobacterium phlei perrugosum Haag. (Cent. f. Bakt., II Abt., *71*, 1927, 6.) From soils and manure.

Mycobacterium phlei planum Haag (*loc. cit.*). From soils.

Mycobacterium ranicola I and *II* Haag (*loc. cit.*). From frogs.

Mycobacterium rubrum Söhngen (*loc. cit.*). From garden earth.

Mycobacterium smegmatis (Trevisan) Chester. (Smegma bacillus, Alvarez and Tavel, Arch. Phys. norm. et path., *6*, 1885, 303; *Bacillus smegmatis* Trevisan, I generi e le specie delle Batteriacee, 1889, 14; *Bacterium smegmatis* Migula, Syst. d. Bakt., *2*, 1900, 497; Chester, Man. Determ. Bact., 1901, 357.) From smegma. Weber (Arb. kaiserl. Gesundheitsamte, *19*, 1902, 251) finds *Mycobacterium smegmatis* acid- but not alcohol-fast in contrast to the mammalian

tubercle bacilli which are both acid- and alcohol-fast. Later observers (Bynoe, Thesis, McGill University, Montreal, 1931) have not found this a valid distinction.

Mycobacterium smegmatis var. *muris* Galli-Valerio. (Cent. f. Bakt., I Abt., Orig., *75*, 1915, 49.) From the preputial glands of the black rat (*Mus rattus*).

Mycobacterium stercoris Bergey et al. (Mist Bacillus, Moeller, Berlin. thierärztl. Wochnschr., 1898, 100; *Mycobacterium stercusis* (sic) Bergey et al., Manual, 1st ed., 1923, 378; Bergey et al., Manual, 4th ed., 1934, 542.) From manure.

Mycobacterium testudinis Friedmann and Piorkowski. (See Haag, Cent. f. Bakt., II Abt., *71*, 1927, 5; apparently the same as *Mycobacterium testudo*, *loc. cit.*, 10.) This is probably *Mycobacterium friedmannii*. From turtles.

Appendix II: Krassilnikov (Mikrobiol., *7*, 1938, 335; and Ray Fungi and Related Organisms, Izd. Acad. Nauk. Moskow, 1938, 121–130) describes a genus *Mycococcus* distinct from Hansgirg's (Österr. Bot. Ztschr., *38*, 1888, 266) family *Mycococcaceae* (which is related to the fungi) and distinct from *Mycococcus* Bokor (Arch. f. Mikrobiol., *1*, 1930, 1).

Mycococcus Krassilnikov includes species that produce coccus-like cells, genetically related to the species included in *Mycobacterium;* reproduction is by fission or budding in different directions, often forming short, irregular chains with side branches; in old cultures, the vegetative cells change into resting cells, the latter germinating in a manner similar to the spores of actinomycetes. Seven species are listed, with incomplete descriptions. *Mycococcus ruber*, *M. capsulatus*, *M. luteus*, *M. citreus* and *M. albus* are described in Krassilnikov's original paper. One of these (*Mycococcus luteus*) is dropped in his later monograph while descriptions of two new species are added (*Mycococcus tetragenus* and *M. mucosus*).

FAMILY II. ACTINOMYCETACEAE BUCHANAN.*

(Jour. Bact., *3*, 1918, 403.)

Mycelium is non-septate during the early stages of growth but later may become septate and break up into short segments, rod-shaped or spherical in shape, or the mycelium may remain non-septate and produce spores on aerial hyphae. The organisms in culture media are either colorless or produce various pigments. Some species are partially acid-fast. This family is distinguished from the previous one by the formation of a true mycelium. As compared with the next family, it is characterized by the manner of spore formation.

Key to the genera of family **Actinomycetaceae.**

I. Obligate aerobic. The colonies are bacteria-like in nature, smooth, rough or folded, of a soft to a dough-like consistency, sometimes compact and leathery in young stages. Most forms do not produce any aerial mycelium; a few produce a limited mycelium, the branches of which also break up into oidiospores or segmentation spores. Some species are partially acid-fast.

Genus I. *Nocardia*, p. 892.

II. Anaerobic or microaerophilic, parasitic; non-acid-fast, non-proteolytic and non-diastatic.

Genus II. *Actinomyces*, p. 925.

Genus I. Nocardia *Trevisan.*

(Trevisan, I generi e le specie delle Batteriacee, 1889, 9; *Actinomyces* Gasperini, Cent. f. Bakt., *15*, 1894, 684 and Atti dell' XI congresso med. internaz. Roma, *6*, 1895, 82; not *Actinomyces* Harz, Jahresber. d. Münch. Thierarzneischule for 1877–1878, 1879, 125; *Actinobacterium* Haas, Cent. f. Bakt., I Abt., Orig., *40*, 1906, 180; Sampietro, Ann. d'Igiene, Roma, *18*, 1908, 331; *Actinococcus* Beijerinck, Folio Microbiol., Delft, *3*, 1914, 196; not *Actinococcus* Kützing, Species Algarum, 1849; *Brevistreptothrix* Lignières, Ann. Parasit. hum. et comp., *2*, 1924, 1; *Asteroides* Puntoni and Leonardi, Boll. e Atti d. R. Accad. Med., *61*, 1935, 90; *Proactinomyces* Jensen, Proc. Linn. Soc. New So. Wales, *56*, 1931, 345.) Named for Prof. E. Nocard who first described the type species.

Slender filaments or rods, frequently swollen and occasionally branched, forming a mycelium which after reaching a certain size assumes the appearance of bacterium-like growths. Shorter rods and coccoid forms are found in older cultures. Conidia not formed. Stain readily, occasionally showing a slight degree of acid-fastness. Non-motile. No endospores. Aerobic. Gram-positive. The colonies are similar in gross appearance to those of the genus *Mycobacterium*. Paraffin, phenol and m-cresol are frequently utilized as a source of energy.

In their early stages of growth on culture media (liquid or solid), the structure of nocardias is similar to that of actinomyces in that they form a typical mycelium hyphae branch abundantly, the branching being true. The diameters of the hyphae vary between 0.5 and 1 micron, usually 0.7 to 0.8 micron, according to the species. The mycelium is not septate. However, the further development of nocardias differs sharply from that of actinomyces: the filaments soon form transverse walls and the whole mycelium breaks up into regularly cylindrical short cells, then into coccoid

* Completely revised by Prof. S. A. Waksman, New Jersey Experiment Station, New Brunswick, New Jersey and Prof. A. T. Henrici, University of Minnesota, Minneapolis, Minnesota, May, 1943.

cells. On fresh culture media, the coccoid cells germinate into mycelia. The whole cycle in the development of nocardias continues for 2 to 7 days. Most frequently the coccoid cells are formed on the third to fifth day, but in certain species (e.g., *Nocardia rubra*) they can be found on the second day.

Numerous chlamydospores may be found in older cultures of nocardias. They are formed in the same way as the chlamydospores in true fungi: the plasma inside the filaments of the mycelium condenses into elongated portions. In older cultures of nocardias many coccoid cells are changed into resistant cells. The latter are larger than the vegetative coccoid cells; the plasma of these cells is thicker than the plasma of vegetative cells; on fresh media they germinate like the spores of actinomyces; they form 2 to 3 germ tubes. Besides the cells mentioned, numerous involution forms can often be found in older cultures of nocardias; the cells are thin, regularly cylindrical or coccoid, are often transformed into a series of spherical or elliptical ampules and a club-like form (2 to 3 microns and more).

The multiplication of nocardias proceeds by fission and budding; occasionally they form special spores. Budding occurs often. The buds are formed on the lateral surface of the cells; when they have reached a certain size, they fall off and develop into rod-shaped cells or filaments. The spores are formed by the breaking up of the cell plasm into separate portions usually forming 3 to 5 spores; every portion becomes rounded, covered with a membrane and is transformed into a spore; the membrane of the mother cell dissolves and disappears. The spores germinate in the same way as those of actinomyces. They form germ tubes which develop into a mycelium.

The colonies of nocardias have a paste-like or mealy consistency and can easily be taken up with a platinum loop; they spread on glass and occasionally render the broth turbid. The surface colonies are smooth, folded or wrinkled. Typical nocardias never form an aerial mycelium, but there are cultures whose colonies are covered with a thin coating of short aerial hyphae which break up into cylindrical oidiospores.

Many species of nocardias form pigments; their colonies are of a blue, violet, red, yellow or green color; more often the cultures are colorless. The color of the culture serves as a stable character.

Krassilnikov (Ray fungi and related organisms, Izd. Acad. Nauk, U.S.S.R., Moscow, 1938) divides the genus into two groups: 1. Well developed aerial mycelium; substrate mycelium seldom produces cross-walls; the threads break up into long, thread-like rods; branches of the aerial mýcelium produce segmentation spores and oidiospores; the latter are cylindrical with sharp ends; no spirals or fruiting branches. This group is the same as group B of Jensen (*loc. cit.*). 2. Typical forms; mycelium develops only at early stages of growth, then breaks up into rod-shaped and coccoid bodies; smooth and rough colonies, dough-like consistency; never form an aerial mycelium; similar to bacterial colonies; aerial mycelium may form around colonies. This genus can also be divided, on the basis of acid-fastness, into two groups: Group 1. Partially acid-fast organisms, which are non-proteolytic, non-diastatic and utilize paraffin; usually yellow, pink, or orange-red in color. Group 2. Non-acid-fast organisms, which are diastatic, largely proteolytic and do not utilize paraffin; yellow, orange to black in color.

The type species is *Nocardia farcinica* Trevisan.

Key to the species of genus **Nocardia.**

I. Partially acid-fast* organisms with strongly refractive cells; non-proteolytic and generally non-diastatic; constantly capable of utilizing paraffin.

---

* Acid-fastness is not marked in cultures, is apparent in infected tissues, pronounced in sputum or other exudates.

A. Initial mycelium well developed, richly branching, dividing into rods and generally into cocci.
    1. Vegetative mycelium soft, without macroscopically visible aerial mycelium.
        a. Vegetative mycelium yellow, orange or red.
            b. Pathogenic.
                c. Vegetative mycelium white, buff, or pale yellow.
                    1. *Nocardia farcinica.*
                cc. Vegetative mycelium yellow to red.
                    2. *Nocardia asteroides.*
            bb. Not pathogenic.
                    3. *Nocardia polychromogenes.*
        aa. Vegetative mycelium white to pink.
            b. Gelatin not liquefied.
                c. Growth on nutrient agar opaque, cream-colored; coccoid forms in broth.
                    4. *Nocardia opaca.*
                cc. Growth on nutrient agar watery, no coccoid forms in broth.
                    5. *Nocardia erythropolis.*
                ccc. Growth on nutrient agar pink.
                    d. White aerial mycelium on milk.
                        6. *Nocardia leishmanii.*
                    dd. Pink pellicle on milk.
                        7. *Nocardia caprae.*
                    ddd. Yellow pellicle on milk.
                        8. *Nocardia pretoriana.*
            bb. Gelatin liquefied.
                    9. *Nocardia pulmonalis.*
    2. Vegetative mycelium hard, yellow, with white aerial mycelium; hyphae divide into chains of acid-fast cocci.
                    10. *Nocardia paraffinae.*

B. Initial mycelium very short, rapidly dividing into rods and cocci.
    1. Slowly growing organisms; cells 0.5 to 0.7 micron in diameter.
                    11. *Nocardia minima.*
    2. Rapidly growing organisms; cells 1.0 to 1.2 microns in diameter.
        a. Growth pink.
            b. Cystites (swollen cells) not formed.
                c. No indigotin from indole.
                    12. *Nocardia corallina.*
                cc. Indigotin from indole.
                    13. *Nocardia globerula.*
            bb. Cystites formed.
                    14. *Nocardia salmonicolor.*
        aa. Growth coral red.
                    15. *Nocardia rubropertincta.*
        aaa. Growth dark red.
                    16. *Nocardia rubra.*
        aaaa. Growth white.
            b. No aerial mycelium.
                    17. *Nocardia coeliaca.*
            bb. Aerial mycelium.
                    18. *Nocardia transvalensis.*

II. Non-acid-fast organisms with weakly refractive cells; no distinct formation of cocci. Constantly diastatic.

A. Not proteolytic.

1. Growth on agar pale cream.
   19. *Nocardia mesenterica.*
2. Growth on agar yellow.
   20. *Nocardia flava.*
3. Growth on agar green.
   21. *Nocardia viridis.*
4. Growth on agar yellow-green.
   22. *Nocardia citrea.*
5. Growth on agar pink to crimson.
   23. *Nocardia madurae.*
6. Growth consistency soft, sparse aerial mycelium.
   24. *Nocardia lutea.*
7. Growth consistency medium, good aerial mycelium.
   25. *Nocardia blackwellii.*
8. Good action on milk. Growth consistency firm, liberal, aerial mycelium.
   26. *Nocardia cuniculi.*
9. Deep brown pigment on protein media.
   27. *Nocardia rangoonensis.*
10. Light brown pigment on protein media.
   28. *Nocardia caviae.*

B. Proteolytic.

1. Growth on nutrient agar with rapid formation of unbranched diphtheroid-like rods; no typical cystites; broth turbid.
   29. *Nocardia actinomorpha.*
2. Growth on nutrient agar with extensive mycelia; simple unbranched rods not formed; cystites present. Broth clear.
   30. *Nocardia flavescens.*
3. Colonies orange-yellow to orange-red, which may change to black.
   31. *Nocardia maculata.*
4. Light brown pigment on protein media.
   32. *Nocardia rhodnii.*
5. Green to greenish-brown pigment on protein media.
   33. *Nocardia gardneri.*

1. **Nocardia farcinica** Trevisan. (Bacille du farcin, Nocard, Ann. Inst. Past., *2*, 1888, 293; Trevisan, I generi e le specie delle Batteriacee, Milan, 1889, 9; *Streptotrix farcinica* Rossi Doria, Ann. d. Ist. d'Igi. Sper. Univ. di Roma, *1*, 1891, 424; *Actinomyces farcinicus* Gasperini, Ann. Ist. d'Igiene, Roma, *2*, 1892, 222; *Oospora farcinica* Sauvageau and Radais, Ann. Inst. Past., *6*, 1892, 248; *Actinomyces bovis farcinicus* Gasperini, Cent. f. Bakt., *15*, 1894, 684; *Bacillus farcinicus* Gasperini, *ibid.*; *Cladothrix farcinica* Macé, Traité de Bactériologie, 3rd ed., 1894, 1047; *Streptothrix farcini bovis* Kitt, Bakterienkunde und pathologische Mikroskopie, Vienna, 3 Aufl., 1899, 511; *Bacterium nocardi* Migula, Syst. d. Bakt., *2*, 1900, 345; *Streptothrix nocardii* Foulerton, Jour. Compt. Path. and Therap., *14*, 1901, 51; *Discomyces farcinicus* Gedoelst, Les champignons parasites de l'homme et des animaux domestiques, Brussels, 1902, 167; *Ac-*

tinomyces nocardii Buchanan, Veterinary Bacteriology, Philadelphia, 1911, 378; *Nocardia albida* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 271, according to Dodge, Medical Mycology, St. Louis, 1935, 746.) From M. L. *farcinicus*, of farcy.

Filaments 0.25 micron in thickness, branched. Markedly acid-fast.

Gelatin colonies: Small, circular, transparent, glistening.

Gelatin stab: No liquefaction.

Agar colonies: Yellowish-white, irregular, refractive, filamentous.

Agar slant: Grayish to yellowish-white growth, surface roughened.

Broth: Clear, with granular sediment, often with gray pellicle.

Litmus milk: Unchanged.

Potato: Abundant, dull, crumpled, whitish-yellow growth.

Nitrites not produced from nitrates.

No soluble pigment formed.

Proteolytic action absent.

Starch not hydrolyzed.

Aerobic, facultative.

Optimum temperature 37°C.

Source: From cases of bovine farcy.

Habitat: Associated with a disease in cattle, resembling chronic tuberculosis. Transmissible to guinea pigs, cattle and sheep, but not to rabbits, dogs, horses or monkeys.

2. **Nocardia asteroides** (Eppinger) Blanchard. (*Cladothrix asteroides* Eppinger, Beitr. z. path. Anat., *9*, 1891, 287; *Streptotrix* (sic) *eppingerii* Rossi Doria, Ann. Inst. d'Ig. sper. d. Univ. Roma, *1*, 1891, 423; *Streptotrix* (sic) *asteroides* Gasperini, Ann. Inst. d'Ig. sper. d. Univ. Roma, *2*, 1892, 183; *Oospora asteroides* Sauvageau and Radais, Ann. Inst. Past., *6*, 1892, 252; *Actinomyces asteroides* Gasperini, Cent. f. Bakt., *15*, 1894, 684; Blanchard, in Bouchard, Traité Path. Gén., *2*, 1895, 811; *Discomyces asteroides* Gedoelst, Champ. Paras. Homme et Anim., 1902, 173; *Actinomyces eppingeri* Namyslowski, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 566; *Asteroides asteroides* Puntoni and Leonardi, Boll. e Atti d. R. Accad. Med. di Roma, *61*, 1935, 92; *Mycobacterium asteroides*, quoted from Puntoni and Leonardi, *idem; Proactinomyces asteroides* Baldacci, Soc. Internat. di Microb., Boll. d. Sez. Ital., *9*, 1937, 141.) From Greek *aster*, star and *eidos*, shape.

Probable synonyms: *Streptotrix aurantiaca* Rossi Doria, *loc. cit.*, 417 (*Actinomyces aurantiacus* Gasperini, *loc. cit.*, 1892, 222; *Oospora aurantiaca* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 388; *Cladothrix aurantiaca* Macé, Traité Pratique de Bact., 4th ed., 1901, 1096; *Nocardia aurantiaca* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 268) and *Streptothrix freeri* Musgrave and Clegg, Philippine Jour. Sci., Med. Sciences, *2*, 1907, 477 (*Discomyces freeri* Brumpt, Précis de Parasitol., Paris, 1st ed., 1910, 858; *Nocardia freeri* Pinoy, Bull. Inst. Past., *11*, 1913, 936; *Oospora freeri* Sartory, Champ. Paras. Homme et Anim., 1923, 785; *Actinomyces freeri* Bergey et al., Manual, 1st ed., 1923, 346). According to Chalmers and Christopherson (*loc. cit.*) another synonym of this organism is *Streptothrix hominis* Sabrazès and Rivière, Le Semaine Médecine, 1895, no. 44.

Straight, fine mycelium, 0.2 micron in thickness, which breaks up into small, coccoid conidia. Acid-fast.

Gelatin stab: Yellowish surface growth. No growth in stab. No liquefaction.

Synthetic agar: Thin, spreading, orange growth. No aerial mycelium.

Starch agar: Restricted, scant, orange growth.

Plain agar: Much folded, light yellow growth, becoming deep yellow to yellowish-red

Glucose broth: Thin, yellowish pellicle.

Litmus milk: Orange-colored ring. No coagulation. No peptonization.

Potato: Growth much wrinkled, whitish. becoming yellow to almost brick-red.

Nitrites produced from nitrates.

No soluble pigment formed.

Proteolytic action doubtful.

Starch not hydrolyzed.

Transmissible to rabbits and guinea pigs but not to mice.

Aerobic.

Optimum temperature 37°C.

Source: From a cerebral abscess in man.

Habitat: Also found in conditions resembling pulmonary tuberculosis.

A number of strains of acid-fast actinomycetes isolated from human lesions have deviated in certain particulars from the description of *Nocardia asteroides*, but not sufficiently to warrant separation as species. The following varieties are described by Baldacci (Mycopathologia, *1*, 1938, 68):

Nocardia asteroides var. *crateriformis* (Baldacci) *comb. nov.* (*Proactinomyces asteroides* var. *crateriformis* Baldacci, *loc. cit.*) Less tendency to fragmentation of mycelium. Complete lack of aerial mycelium. Growing as discrete colonies, disk- or crater-shaped.

Nocardia asteroides var. *decolor* (Baldacci) *comb. nov.* (*Proactinomyces asteroides* var. *decolor* Baldacci, *loc. cit.*) Greater tendency to produce white aerial mycelium; vegetative mycelium colorless.

Nocardia asteroides var. *gypsoides* (Baldacci) *comb. nov.* (*Actinomyces gypsoides* Henrici and Gardner, Jour. Inf. Dis., *28*, 1921, 248; *Discomyces gypsoides* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 980; *Oospora gypsoides* Sartory, Champ. Paras. Homme et Anim., 1923, 802; *Proactinomyces asteroides* var. *gypsoides* Baldacci, *loc. cit.*) White aerial mycelium; darkening of peptone media.

3. Nocardia polychromogenes (Vallée) *comb. nov.* (*Streptothrix polychromogenes* Vallée, Ann. Inst. Past., *17*, 1903, 288; *Streptothrix pluricromogena* Caminiti, Cent. f. Bakt., I Abt., Orig., *44*, 1907, 198; *Actinomyces polychromogenes* Lieske, Morphol. u. Biol. d. Strahlenpilze, Leipzig, 1921, 32; *Proactinomyces polychromogenes* Jensen, Proc. Linnean Soc. New So. Wales, *56*, 1931, 79 and 363; *Oospora polychromogenes* Sartory, quoted from Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 51; *Actinomyces plurichromogenus* Dodge, Medical Mycology, St. Louis, 1935, 737.) From Greek, producing many colors.

Description from Jensen (*loc. cit.*).

Long wavy filaments: 0.4 to 0.5 by 70 to 100 microns, extensively branched but without septa. Older cultures consist entirely of rods 4 to 10 microns, frequently in V, Y, or smaller forms. Still older cultures consist of shorter rods and coccoid forms. Gram-positive, frequently showing bands and granules.

Gelatin stab: Thin yellowish growth along the stab with thin radiating filaments. Surface growth flat, wrinkled, red. No liquefaction.

Nutrient agar: Scant, orange-red growth.

Glucose agar: After 3 to 4 days raised, flat, glistening, rose-colored growth. After 1 to 3 weeks becoming folded and coral-red.

Glucose broth: After 3 to 4 days turbid; after 2 to 3 weeks an orange flaky sediment. No surface growth.

Milk: Growth starts as small orange-colored surface granules. After 1 to 2 weeks a thick, soft, orange-colored sediment forms.

Optimum temperature 22° to 25°C.

Distinctive characters: Differs from *Nocardia corallina* in the formation of very long filaments and in filiform growth in gelatin stabs.

Source: From the blood of a horse; from soil in France and Australia.

Habitat: Soil.

4. Nocardia opaca (den Dooren de Jong) *comb. nov.* (*Mycobacterium opacum* den Dooren de Jong, Cent. f. Bakt., II Abt., *71*, 1927, 216; *Mycobacterium crystallophagum* Gray and Thornton, Cent.

f. Bakt., II Abt., 73, 1928, 86; *Actinomyces crystallophagus* Bergey et al., Manual, 3rd ed., 1930, 473; *Proactinomyces opacus* Jensen, Proc. Linnean Soc. New So. Wales, 57, 1932, 369; *Proactinomyces crystallophagus* Reed, in Manual, 5th ed., 1939, 834.) From Latin *opacus*, shady, darkened.

Description from Gray and Thornton (*loc. cit.*), Bynoe (Thesis, McGill University, Montreal, 1931), and Jensen (*loc. cit.*).

Long, curved, irregular and branching filaments or rods: 0.8 to 1.0 by 2 to 16 microns, or occasionally longer. Few chains or clumps are formed. In older cultures shorter rods or cocci are generally formed. Readily stained. Not acid-fast. Gram-positive.

Gelatin colonies: Round, convex, whitish, smooth, shining, edges slightly arborescent. Deep colonies: Burrs, with slightly irregular processes.

Gelatin stab: Convex, whitish, smooth, resinous, filiform, erose.

Broth: Turbid with broken white scum, or clear with granular suspension.

Dorset's egg medium: Spreading, smooth, moist, salmon-colored growth.

Loeffler's medium: Scanty growth, smooth, moist, light buff-colored.

Glycerol potato: Dry, rough, crumpled, pink to buff-colored growth.

Litmus milk: Grayish pellicle; slightly alkaline.

Nitrites are produced from nitrates.

No acid from sucrose, lactose, maltose or glucose.

Phenol and naphthalene are utilized as sources of energy.

Optimum pH 6.8 to 7.3.

Optimum temperature 30°C.

Distinctive characters: Differs from *Nocardia corallina* and *Nocardia polychromogenes* in that the cells are much longer than those of the former and much shorter than those of the latter. Grows in smooth convex surface colonies and burr-like deep colonies.

Source: Twenty-four strains isolated from soils in Great Britain.

Habitat: Probably sparingly distributed in soils.

5. **Nocardia erythropolis** (Gray and Thornton) *comb. nov.* (*Mycobacterium erythropolis* Gray and Thornton, Cent. f. Bakt., II Abt., 73, 1928, 87; *Actinomyces erythropolis* Bergey et al., Manual, 3rd ed., 1930, 472; *Proactinomyces erythropolis* Jensen, Proc. Linnean Soc. of New So. Wales, 57, 1932, 371.) From Greek *erythrus*, red and *polis*, city.

Description from Gray and Thornton (*loc. cit.*) and from Bynoe (Thesis, McGill University, Montreal, 1931).

Long uneven-sided rods and filaments, curved and branching up to 11 microns long by 0.8 micron. Coccoid forms not formed. Stains readily. Not acid-fast. Gram-positive.

Gelatin colonies: After 12 days, round, flat, white, shining; edge entire. Deep colonies: Round, smooth.

Gelatin stab: After 8 to 14 days, convex, white, smooth, shining, radiate from center, borders cleft. Line of puncture filiform, erose.

Agar colonies: Round, 2 to 3 mm in diameter, convex, watery-white; edge entire. Deep colonies: Lens-shaped.

Agar slant: Filiform, flat, watery growth; edge undulate.

Broth: Growth slight, turbid.

Dorset's egg medium: After 2 weeks, raised, moist, finely granular, irregular margin, flesh-colored.

Loeffler's medium: After 7 days growth as on Dorset's egg medium, but pink.

Glycerol potato: After 7 days, flat, dry, rough, orange-colored.

Litmus milk: Pale pink pellicle.

Nitrites not produced from nitrates.

No acid from glucose, lactose, sucrose or glycerol.

Phenol is utilized.

Optimum pH 6.8 to 8.0.

Optimum temperature 25°C.

Distinctive characters: Differs from *Nocardia coeliaca* and *Nocardia actinomorpha* in the filiform growth and absence of liquefaction of gelatin. Long rods and filaments.

Source: Six strains isolated from soils in Great Britain.

Habitat: Presumably soil.

6. **Nocardia leishmanii** Chalmers and Christopherson. (A new acid-fast streptothrix, Birt and Leishman, Jour. Hyg., *2*, 1902, 120; Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 255; *Discomyces leishmani* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 984; *Actinomyces leishmani* Sartory and Bailly, Mycoses pulmonaires, 1923, 253.) Named for Leishman, one of the original isolators.

Description from Erikson (*loc. cit.*, p. 27).

Initial cells frequently swollen, large and irregular, aggregated in short chains and then branching out into regular narrow filaments; at margin of colony on synthetic glycerol agar may be seen comparatively long thick segments with accompanying fringe of normal hyphae; later entire colonies asteroid in appearance, very fine and close angular branching, with aerial hyphae situated singly; aerial mycelium generally abundant with irregularly cylindrical conidia. Slightly acid-fast. The latter property must have been attenuated during artificial cultivation, for the organism is reported as markedly acid-fast by the original isolators.

Gelatin: Small pink colonies in depths of stab. No liquefaction.

Glucose agar: Rounded elevated colonies with paler frosting of aerial mycelium; growth becoming piled up, aerial mycelium sparse.

Glycerol agar: Small round pink colonies, tending to be umbilicated and piled up, stiff white aerial spikes.

Coon's agar: Small round colorless colonies, stiff white aerial spikes; later a pink tinge.

Potato agar: Minute colorless round colonies, small raised patches of white aerial mycelium.

Dorset's egg medium: Colorless confluent growth studded with little wart-like projections bearing stiff aerial spikes; growth becomes pinkish with a white aerial mycelium; later, growth drab gray, medium discolored.

Serum agar: Minute round colorless colonies with pinkish tinge in confluent raised patch.

Inspissated serum: Small round pale pink colonies, umbilicated and raised up.

Broth: Liberal growth, white flocculent colonies; later pink surface colonies.

Synthetic sucrose solution: Colorless flocculent sediment, thin colorless pellicle.

Milk: Surface growth, white aerial mycelium, solid coagulum; later partly peptonized with pink aerial mycelium.

Litmus milk: Pink surface growth, aerial mycelium, milky opaque after 40 days.

Carrot plug: Small irregularly round raised colonies, colorless, covered with stiff aerial spikes; later buff-colored, convoluted and ribbed growth with small patches of white aerial mycelium; aerial mycelium pink in two months.

Source: From fatal case of lung disease and pericarditis in man.

Habitat: Human infections so far as known.

7. **Nocardia caprae** (Silberschmidt) *comb. nov.* (*Streptothrix caprae* Silberschmidt, Ann. Inst. Past., *13*, 1899, 841; *Cladothrix caprae* Macé, Traité Pratique de Bact., 4th ed., 1901, 1094; *Discomyces caprae* Gedoelst, Champ. Paras. Homme et Anim., 1902, 174; *Oospora caprae* Sartory, Champ. Paras. Homme et Anim., 1923, 813; *Actinomyces caprae* Ford, Textb. of Bact., 1927, 205.) From Latin *capra*, goat.

Description from Erikson (Med. Res. Council Spec. Rept. Ser. 203, 1935, 26).

Initial cells only slightly enlarged; early development of aerial hyphae, while substratum threads are still short; frequent slipping of branches; aerial mycelium abundant on all media with tendency to form coherent spikes; mycelium not very polymorphous, but occasional thicker segments appear. Slightly acid-fast.

Gelatin: Extensive dull growth with small raised patches of pink aerial mycelium; later ribbon-like, depressed. No liquefaction.

Glucose agar: Irregular bright pink growth tending to be heaped up; later abundant masses frosted over with thin white aerial mycelium.

Glycerol agar: Abundant growth, small round pink colonies, partly covered with white aerial mycelium.

Potato agar: Extensive thin growth, pink in raised patches, covered by white aerial mycelium; later aerial mycelium also becomes pink.

Starch agar: Minute colorless colonies covered by white aerial mycelium.

Blood agar: Minute round colorless colonies aggregated in broad pink zones, paler aerial mycelium. No hemolysis.

Dorset's egg medium: Few colorless colonies, some pink, white aerial mycelium; later, growth becoming dull pink, irregular, with scant white aerial mycelium.

Ca-agar: Minute colorless colonies, white aerial mycelium; later a pinkish tinge.

Serum agar: Small round pink colonies frosted over with thin white aerial mycelium.

Inspissated serum: No growth.

Broth: Superficial pellicle composed of pink colonies with white aerial mycelium; moderate flocculent sediment.

Glucose broth: Small sediment of fine flocculi; later pellicle composed of small pink colonies; superficial skin entire and salmon-colored in 16 days.

Synthetic glycerol solution: Round pink disc-like colonies on surface and tenuous white wispy growth in suspension and sediment; after 20 days, surface colonies bearing white aerial mycelium extending 2 cm up tube.

Synthetic sucrose solution: Minute white colonies in suspension and sediment in 3 days; thin dust-like pellicle in 10 days; some surface colonies with white aerial mycelium in 17 days.

Milk: Red surface skin; solid coagulum.

Litmus milk: Red surface growth, no change in liquid; after 4 weeks, liquid decolorized, opaque.

Potato plug: Abundant growth, small colonies, mostly confluent, entirely covered with pale pink aerial mycelium; growth becomes membranous, considerably buckled; later superficial colonies with pink aerial mycelium on liquid at base of tube, bottom growth of round white colonies.

Starch not hydrolyzed.

Source: From lesions in goats.

8. **Nocardia pretoriana** Pijper and Pullinger. (Pijper and Pullinger, Jour. Trop. Med. Hyg., *30*, 1927, 153; *Actinomyces pretorianus* Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 38.) Named for Pretoria in South Africa.

Description from Erikson. (Med. Res. Council Spec. Rept. Ser. 203, 1935, 30).

Minute flat colonies are formed consisting of angularly branched filaments, and bearing a few short straight aerial hyphae; later the growth becomes spreading and extensive, the slipping of the branches is well marked and the aerial hyphae are divided into cylindrical conidia. Slightly acid-fast.

Gelatin: A few colorless flakes. No liquefaction.

Glucose agar: Pale buff umbilicated and piled up colonies.

Glycerol agar: Piled up pink mass, very scant white aerial mycelium at margin.

Ca-agar: Yellowish wrinkled coherent growth with white aerial mycelium on apices and at margin.

Coon's agar: Colorless mostly submerged growth, scant white aerial mycelium.

Dorset's egg medium: A few round colorless colonies in 3 days; after 3 weeks, irregular raised pink mass, warted appearance, moderate degree of liquefaction.

Serum agar: Raised, convoluted, slightly pinkish growth.

Inspissated serum: No growth.

Broth: Moderate quantity of flakes and dust-like surface growth.

Synthetic sucrose solution: A few colorless flakes on the surface, lesser bottom growth.

Milk: Yellowish surface growth; solid coagulum in one month; later, partly digested, pale pink growth up the wall of the tube.

Litmus milk: Colorless surface growth, liquid blue; becoming hydrolyzed and decolorized.

Potato plug: Small raised pale pink colonies with white aerial mycelium; after 2 months, plug and liquid discolored, growth dull buff, dry and convoluted at base, round and zonate at top of slant, white aerial mycelium, surface and bottom growth on liquid.

Source: From a case of mycetoma of the chest wall in a South African native.

Habitat: Human infections so far as known.

9. **Nocardia pulmonalis** (Burnett) *comb. nov.* (*Actinomyces pulmonalis* Burnett, Ann. Rept. N. Y. State Vet. Coll., 1909–1910, 167.) From Latin *pulmo*, lung.

Gram-positive mycelium breaking up readily into oval-shaped conidia. Acid-fast, especially in early stages of growth.

Gelatin: Small, whitish, spherical colonies; edges of colony becoming chalky white; limited liquefaction.

Agar: Moist, raised growth in the form of small, spherical colonies.

Glucose agar: Dull, whitish, convoluted growth.

Broth: Delicate, translucent film on surface, becoming corrugated with some whitish, spherical colonies in medium.

Milk: Colonies on the surface of the medium; milk is coagulated in a few days, later digested.

Potato: Luxuriant growth in the form of small, translucent, round colonies; becoming colored lemon-yellow; later, growth becomes convoluted or folded with chalky white aerial mycelium, color of plug brownish.

Non-pathogenic for rabbits and guinea pigs.

Aerobic.

Source: From the lungs of a cow.

Habitat: Bovine infections so far as known.

10. **Nocardia paraffinae** (Jensen) *comb. nov.* (*Proactinomyces paraffinae* Jensen, Proc. Linn. Soc. New So. Wales, *56*, 1931, 362.) From M. L. *paraffina*, paraffine.

In agar media, the organism initially forms an extensive mycelium of long, richly-branching hyphae, 0.4 to 0.5 micron thick. After 5 to 6 days, at room temperature, numerous end branches swell to about double thickness, become more refractive, exhibit fine incisions along their external contours, and divide into oval, spore-like elements, 0.8 to 1.0 by 1.2 to 1.5 microns. This process of division starts at the tips of the swollen branches and proceeds basipetally until most of the hyphae appear divided. Primary septa have not been seen in the hyphae. A similar process of division takes place in liquid media, where also the filaments often fall into fragments of variable length. The spore-like elements, but not the undivided filaments, are markedly acid-fast. The aerial mycelium consists of rather short, straight, not very much branched hyphae, 0.4 to

0.6 micron thick, which never show any differentiation into spores.

Gelatin: No liquefaction.

Sucrose agar: Very scant growth. Thin colorless veil, sometimes with a trace of white aerial mycelium.

Glucose agar: Fair growth. Vegetative mycelium flat, growing into medium; pale ochre-yellow to orange, with raised outgrowths on the surface. Growth of a crumbly consistency. Scant, white, aerial mycelium.

Nutrient agar: Slow but good growth. Vegetative mycelium superficial, somewhat raised, ochre-yellow, hard, but with a loose, smeary surface. Aerial mycelium scant, small white tufts. No pigment.

Potato: Fair growth. Vegetative mycelium granulated, first pale-yellow, later deep ochre-yellow to orange. Scant, white, aerial mycelium. No pigment.

Liquid media (milk, broth, synthetic solutions): Small, round granules of various yellow to orange colors, firm, but can be crushed into a homogeneous smear. In old broth cultures a thick, hard, orange to brownish surface pellicle is formed.

Sucrose not inverted.

Starch not hydrolyzed.

Cellulose is not decomposed.

Nitrates are not reduced to nitrites.

Milk is not coagulated or digested.

Final reaction in glucose NH_4Cl solution, pH 4.6 to 4.4.

All strains show a marked power of utilizing paraffin wax as a source of energy.

Source: Isolated from soil.

Habitat: Soil.

11. **Nocardia minima** (Jensen) *comb. nov.* (*Proactinomyces minimus* Jensen, Proc. Linnean Soc. New So. Wales, *56*, 1931, 365.) From Latin *minimus*, very small.

Filaments and rods: 0.4 to 0.6 by 2 to 10 microns. In older cultures mostly short rods, frequently V, Y, swollen forms, or cocci. Irregularly stained with ordinary dyes, generally show bars and bands. Generally a few cells from cultures are acid-fast, most are not acid-fast. Gram-positive.

Gelatin stab: Filiform, granulated, cream-colored growth. No liquefaction.

Agar: Slow growth, raised, folded, with finely myeloid margins. At first colorless, after 6 to 8 weeks flesh pink or coral pink.

Potato: Growth slow, after 6 to 8 weeks abundant, spreading, much raised, finely wrinkled, coral pink.

Paraffin is utilized.

Optimum temperature 22° to 25° C.

Distinctive characters: Closely resembles *Nocardia corallina* but differs in the much slower growth and the smaller size of the cells.

Source: From soil in Australia.

Habitat: Soil.

12. **Nocardia corallina** (Bergey et al.) *comb. nov.* (*Bacillus mycoides corallinus* Hefferan, Cent. f. Bakt., II Abt., *11*, 1904, 459; *Serratia corallina* Bergey et al., Manual, 1st ed., 1923, 93; *Streptothrix corallinus* Reader, Jour. Path. and Bact., *29*, 1926, 1; *Mycobacterium agreste* Gray and Thornton, Cent. f. Bakt., II Abt., *73*, 1928, 84; *Actinomyces agrestis* Bergey et al., Manual, 3rd ed., 1930, 472; *Proactinomyces agrestis* Jensen, Proc. Linnean Soc. New So. Wales, *56*, 1931, 345; *Proactinomyces corallinus* Jensen, *ibid.*, *57*, 1932, 364.) From Latin *corallinus*, coral red.

Description from Gray and Thornton (*loc. cit.*), Jensen (*loc. cit.*) and Bynoe (Thesis, McGill University, Montreal, 1931).

Branching rods, generally curved, 1 to 1.5 by 3 to 10 microns. In older cultures generally shorter rods and cocci. Non-motile. Not acid-fast. Gram-positive.

Gelatin colonies: Round, convex, smooth, pink, shining, edge filamentous. Deep colonies: Burrs.

Gelatin stab: Nailhead; line of stab arborescent. No liquefaction.

Agar colonies: Round, convex, or umbonate, smooth, pink, shining or matte; border lighter, edge filamentous or with arborescent projections. Deep colonies: Burrs, or lens-shaped, with arborescent projections. In their very early stages colonies consist of branching filamentous rods. As the colony grows, the cells in the interior break up into short rods and cocci which eventually form the mass of the colony. Cells on the outside remain filamentous, giving the colony a burr-like appearance, and often forming long arborescent processes.

Agar slant: Filiform, convex, smooth, pink, shining or matte; arborescent or with projections from undulate border.

Litmus milk: Alkaline. Reddish pellicle.

Glycerol potato: Filiform, raised, dry, wrinkled, yellowish-brown to coral red.

Broth: Usually turbid. Pink scum.

Dorset's egg medium: Filiform, raised, dry, wrinkled, orange.

Loeffler's medium: Similar to growth on Dorset's egg medium, but pink.

Nitrites produced from nitrates.

Acid from glycerol and glucose with some strains. No acid or gas from sucrose, maltose or lactose.

Phenol and m-cresol are utilized. Some strains utilize naphthalene. (Gray and Thornton.) Some strains utilize phenol or m-cresol (Jensen).

Optimum pH 6.8 to 8.0.

Optimum temperature 22° to 25°C.

Distinctive characters: Soil organism forming *Mycobacterium*-like colonies after 2 to 4 days on simple media. Pale pink chromogenesis. Nailhead growth in gelatin stab. Branching rods and short filaments.

Source: Seventy-four strains isolated from soils in Great Britain and Australia.

Habitat: Soil.

13. **Nocardia globerula (Gray)** ***comb. nov.*** **(*Mycobacterium globerulum* Gray,** Proc. Roy. Soc. London, B, *102*, 1928, 265; *Proactinomyces globerulus* Reed, in Manual, 5th ed., 1939, 838.) From Latin *globus*, a sphere.

Description from Gray (*loc. cit.*) and from Bynoe (Thesis, McGill University, Montreal, 1931).

Curved rods and filaments: 1 by 2 to 9 microns, with many coccoid cells, especially in old cultures. Rods and filaments are frequently irregularly swollen. Not acid-fast. Capsules may be present. Gram-positive.

Gelatin: After 19 days surface colonies irregularly round, 1 to 2 mm in diameter, convex, light buff, smooth, shining; edge entire. Deep colonies: Round, with entire edge.

Gelatin stab: After 8 days nailhead, irregularly round, convex, pinkish-white, smooth, shining; line of stab erose.

Agar: After 4 days surface colonies irregularly round, 3 to 5 mm in diameter, convex, white, smooth, shining; edge undulate, erose. After 7 days, more convex and of a watery appearance. Deep colonies: After 4 days, lens-shaped.

Agar slant: After 3 days, filiform, flat, watery; edge irregular.

Nutrient and peptone broth: Turbid with viscous suspension.

Indole not formed.

Litmus milk: Alkaline.

Glycerol potato: After 24 hours, filiform, moist, smooth, pale pink.

Dorset's egg medium: After 2 weeks, spreading, raised, moist, orange-colored.

Loeffler's medium: Growth as on Dorset's egg medium, but salmon-colored.

Nitrites not produced from nitrates.

No acid from glucose, lactose, maltose, sucrose or glycerol.

Phenol is utilized.

Indole agar: Blue crystals of indigotin formed.

Optimum temperature 25° to 28°C.

Optimum pH 6.8 to 7.6.

Distinctive characters: This organism resembles most closely *Nocardia corallina*. It is distinguished by pro-

ducing a more watery type of surface growth, more nearly entire deep colonies and more particularly by the production of indigotin from indol.

Source: From soil in Great Britain.

Habitat: Presumably soil.

14. **Nocardia salmonicolor** (den Dooren de Jong) *comb. nov.* (*Mycobacterium salmonicolor* den Dooren de Jong, Cent. f. Bakt., II Abt., *71*, 1927, 216; *Flavobacterium salmonicolor* Bergey et al., Manual, 3rd ed., 1930, 157; *Proactinomyces salmonicolor* Jensen, Proc. Linnean Soc. New So. Wales, *57*, 1932, 368.) From Latin *salmo*, salmon and *color*, color.

Closely related to *Nocardia corallina*.

On glucose-asparagine-agar after 18 to 24 hrs., long branching rods are formed, 1.0 to 1.3 microns in thickness, with small refractive granules of aerial mycelium, sometimes stretching into quite long filaments; after 2 to 3 days small definite mycelia are present, and after 5 to 6 days these have largely divided into short rods and cocci; the colonies have the same burr-like appearance as those of *Nocardia corallina*. Many cells at the edge of the colonies show, after 3 to 4 days, club- or pear-shaped swellings, up to 2.5 to 3.0 microns in width; after 5 to 6 days, many of these swollen cells are seen to germinate with the formation of two more slender sprouts. (Ørskov, Investigations into the Morphology of the ray fungi. Copenhagen, 1923, 82, gives an almost identical picture of *Streptothrix rubra;* it is questionable, indeed, whether these two organisms are not really identical.)

Gelatin: At 20° to 22°C, scant arborescent growth in stab; small wrinkled orange surface colony. No liquefaction.

Glucose-asparagine-agar: Good growth, restricted, rather flat, edges lobate, surface warty, glistening, first pale orange, later ochre-yellow; consistency crumbly. After 5 to 6 weeks the growth is paler with many small round raised yellow secondary colonies.

Glucose-nutrient agar: Excellent growth, spreading, flat, dense, edges lobate, surface folded, glistening, yellow, gradually changing to deep orange-red.

Nutrient broth: Fair growth; thin pellicle and granular sediment, at first cream-colored, later red; broth clear at first, slightly turbid after 3 weeks.

Milk: Good growth; pellicle of small cream-colored granules after 2 days, later a thick orange sediment. Not coagulated, but appears slightly cleared after 5 weeks, the reaction becoming alkaline.

Potato. Good growth, raised, warty, crumbly, glistening, at first buff, changing to orange and finally to almost blood-red.

Indole not formed.

Nitrites produced from nitrates.

Nitrate, ammonium salts, asparagine and peptone are utilized almost equally well with glucose as source of carbon, although the growth is most rapid with peptone.

Sucrose not inverted, although readily utilized with sodium nitrate as a source of nitrogen.

Paraffin readily utilized as a source of carbon.

Phenol not utilized.

No acid from glucose or glycerol.

Starch not hydrolyzed.

No growth in oxygen-free atmosphere.

Source: Isolated from soil by means of an ethylamine enriched medium, at 37°C.

Habitat: Probably soil.

15. **Nocardia rubropertincta** (Hefferan) *comb. nov.* (Butterbacillus, Grassberger, Münch. med. Wochnschr., *46*, 1899, 343; *Bacillus rubropertinctus* Hefferan, Cent. f. Bakt., II Abt., *11*, 1903, 460; *Serratia rubropertinctus* Bergey et al., Manual, 1st ed., 1923, 96; *Mycobacterium rubropertinctum* Ford, Textb. of Bact., 1927, 255; *Proactinomyces rubropertinctus* Reed, in Manual, 5th ed.,

1939, 835.) From Latin, colored very red.

Büttner (Arch. Hyg., *97*, 1926, 17) regards *Mycobacterium eos* as probably identical with *Mycobacterium rubrum* Söhngen (Cent. f. Bakt., II Abt., *37*, 1913, 599), Grassberger's organism (*loc. cit.*), Hormann and Morgenrot's organism (Hyg. Rundsch., *7*, 1898, 229), and Weber's organism (Arb. a. d. k. Gesundheitsamte, Berlin, *19*, 1903).

To this list Lehmann and Neumann (Bakt. Diag., 7 Aufl., *2*, 1927, 764) also add the organism of Ascher (Ztschr. f. Hyg., *32*, 1899, 329) and the butter bacillus of Aujeszky (Cent. f. Bakt., I Abt., Orig., *31*, 1902, 132).

Jensen (Proc. Linnean Soc. New So. Wales, *49*, 1934, 32) regards the following organisms as probably identical: *Bacterium rubrum* Migula (Syst. d. Bakt., *2*, 1900, 488) a preliminary description of which is given by Schneider (Arb. bakt. Inst. Karlsruhe, *1*, Heft 2, 1894, 213); probably this is also the organism referred to by Haag (Cent. f. Bakt., II Abt., *71*, 1927, 35) as *Bacterium rubrum*; and *Mycobacterium rubrum* Söhngen (*loc. cit.*).

Description taken from Grassberger (*loc. cit.*), Hefferan (*loc. cit.*) and Jensen (*loc. cit.*).

Small rods: 0.3 to 0.9 by 1.5 to 3.0 microns. Cells in 18 to 24 hour agar culture in beautiful angular arrangement, after 2 to 3 days nearly coccoid, 0.6 by 0.8 micron. Tendency for branching on glycerol agar after 2 to 3 days, but branching does not occur commonly though granules of aerial mycelium are sometimes seen (Jensen). Not acid-fast (Grassberger). Acid-fast (Hefferan). Variable (Jensen). Non-motile. Gram-positive.

Gelatin colonies: Irregular with crenate margin and folded surface. Coral red.

Gelatin stab: Surface growth like the colonies. Growth in stab at first thin, then granular to arborescent with chromogenesis. No liquefaction.

Agar colonies: Small, granular, becoming pink to red depending on composition of agar.

Agar slant: Dry, lustreless (R) to glistening (S), pink to vermillion red.

Broth: Faint uniform turbidity with salmon-pink pellicle (in scales) which is renewed on surface as it settles to form a red sediment (Hefferan, Jensen).

Litmus milk: Thick, fragile, dull coral red surface scales and sediment. Unchanged (Hefferan) to alkaline and somewhat viscid after 3 to 4 weeks (Jensen).

Potato: Slow but excellent intensive red growth becoming dull orange (Jensen).

Nitrites not produced from nitrates; nitrates, ammonia and asparagine are almost as good sources of nitrogen as peptone (Jensen).

Benzine, petroleum, paraffin oil and paraffin are utilized as sources of energy (Söhngen). No action on manganese dioxide (Söhngen, Cent. f. Bakt., II Abt., *40*, 1914, 554).

Optimum pH 6.8 to 7.2. Growth stops at pH 4.9.

Temperature relations: Grows well between 20° and 37°C (Jensen).

Aerobic to facultative anaerobe.

Distinctive characters: *Mycobacterium*-like colonies with coral to vermillion red chromogenesis on asparagine agar, potato, gelatin and other media. Short rods, seldom forms filaments. Generally not acid-fast.

Source: Six cultures isolated from butter (Grassberger). Several cultures isolated from soil in Holland (Söhngen) and Australia (Jensen). Two cultures as contaminants in tuberculin flasks (Hagan, Breed).

Habitat: Probably widely distributed in soil.

16. **Nocardia rubra** (Krassilnikov) *comb. nov.* (*Proactinomyces ruber* Krassilnikov, Bull. Acad. Sci. U. S. S. R., No. 1, 1938, 139.) From Latin *ruber*, red.

Mycelium produced at first but soon breaks up into rods and cocci. The latter multiply by fission, cross-wall formation and budding. Cells are Gram-positive, weakly acid-fast.

Gelatin: No liquefaction.

Colonies smooth or folded and rough, shiny or dull, dark red color. Pigment belongs to the carotinoids, does not diffuse into the medium.

Milk: No coagulation or peptonization.

Sucrose not inverted.

Starch not hydrolyzed.

No growth on cellulose.

Readily assimilates fats and paraffin, and, to a less extent, wax.

Various strains of this organism may vary considerably from type.

Habitat: Soil.

17. **Nocardia coeliaca** (Gray and Thornton) *comb. nov.* (*Mycobacterium coeliacum* Gray and Thornton, Cent. f. Bakt., II Abt., *73*, 1928, 88; *Flavobacterium coeliacum* Bergey et al., Manual, 3rd ed., 1930, 156; *Proactinomyces coeliacus* Reed, in Manual, 5th ed., 1939, 836.)

Description from Gray and Thornton (*loc. cit.*) and from Jensen (Proc. Linnean Soc. New So. Wales, *56*, 1931, 201).

Short, curved, uneven-sided rods: 0.8 by 5 microns with occasional filaments up to 10 to 12 microns long, frequently beaded, occasionally swollen or branched. Coccoid forms 0.8 to 1.2 microns in diameter are common, especially in older cultures. Stain readily. Not acid-fast or occasionally slightly acid-fast. Gram-positive.

Gelatin colonies: After 12 days, irregular, raised, white, rugose, dull, edge entire. Deep colonies: Irregular, smooth or slightly broken.

Gelatin stab: Convoluted, buff-white to yellowish, dull; below surface the growth forms many irregular hollow lobes, giving a glistening appearance, to a depth of 3 to 4 mm.

Agar colonies: After 11 days, less than 1 mm in diameter, round or irregular, raised, white, resinous, edge irregular, burred. Deep colonies: Irregularly round or oval, edge slightly broken.

Agar slant: Filiform, convex, white, rugose, resinous, edge undulate.

Broth: Turbid.

Litmus milk: Slightly alkaline after 5 to 7 days.

Glycerol potato: After 2 days, dry, crumpled, orange, becoming brown after about 10 days.

Dorset's egg medium: Raised, smooth, moist, verrucose, buff-colored.

Loeffler's medium: After 10 days, slight growth, dry, granular, pale buff-colored.

Nitrites are not produced from nitrates.

No acid from glucose, lactose, sucrose or glycerol.

Phenol is utilized.

Optimum pH 7.6 to 8.0.

Optimum temperature 22° to 25°C.

Distinctive characters: Differs from the previously described members of the genus in the absence of chromogenesis. Forms hollow lobes in deep gelatin cultures. Cells are rods, seldom filaments.

Source: From soil in Great Britain and Australia.

Habitat: Presumably soil.

18. **Nocardia transvalensis** Pijper and Pullinger. (Pijper and Pullinger, Jour. Trop. Med. Hyg., *30*, 1927, 153; *Actinomyces transvalensis* Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 46.) Named for the Transvaal, a state of South Africa.

Description from Erikson (Med. Res. Council Spec. Rept. Ser. 203, 1935, 28).

Initial mycelium unicellular, but with the central branch frequently broader and showing dense granular refractile contents, small colonies quickly covered with aerial mycelium, the straight aerial hyphae in some cases becoming clustered into irregular spikes, colorless drops are exuded and a pink coloration produced in

the densest part of the growth on synthetic glycerol agar. Angular branching with division of the substratum filaments can be seen, the aerial hyphae also being irregularly segmented. Acid-fast.

Gelatin: Poor growth, a few irregular colorless flakes. No liquefaction.

Agar: No growth.

Glucose agar: Raised, granular, pink colonies with white aerial mycelium.

Glycerol agar: Small pink coiled masses with thin white aerial mycelium.

Potato agar: No growth.

Coon's agar: Colorless growth with liberal white aerial mycelium.

Dorset's egg medium: Small irregularly raised and coiled dull pink mass.

Serum agar: Very poor growth.

Inspissated serum: Scant colorless flaky growth; later a minute tuft of pale pink aerial mycelium.

Broth: Moderate flaky growth.

Synthetic sucrose solution: Poor growth, a few flakes on surface, a few at bottom.

Potato plug: Dry, raised, convoluted, pink growth with white aerial mycelium in one month; dull, pink, brittle surface colonies, with paler aerial mycelium floating coherently on liquid at base in 2 months.

Milk: No change.

Starch not hydrolyzed.

Source: From a case of mycetoma of the foot in South Africa.

Habitat: Human infections so far as known.

19. **Nocardia mesenterica** (Orla-Jensen) *comb. nov.* (*Microbacterium mesentericum* Orla-Jensen, The Lactic Acid Bacteria, 1919, 181; *Proactinomyces mesentericus* Jensen, Proc. Linnean Soc. New So. Wales, *57*, 1932, 373.) From Greek *mesenterium*, mesentery.

Extensive mycelium composed of richly branching hyphae of a somewhat variable thickness, 0.4 to 0.8 micron; no aerial hyphae are seen. With increasing age the hyphae divide into fragments of varying size and shape, partly diphtheroid rods, but no real cocci. There is, particularly in richer media, a tendency to form large, swollen, fusiform to almost spherical cells, up to 3.5 microns in diameter. These may stain intensely with carbol fuchsin; when transferred to fresh media, they germinate and produce a new mycelium.

Gelatin: Good growth; finely arborescent, cream-colored growth in the stab; raised, folded, pale-yellow, surface colony. No liquefaction.

Glucose-asparagine-agar: Fair growth, narrow, raised, granular, very pale yellow, glistening; condensation water clear, with small granules. At 30°C only scant growth consisting of small irregular white granules, growing deeply down into the agar.

Glucose-nutrient-agar: Good growth, restricted, with undulate edges, surface with high transverse folds, cream-colored; the consistency is firm and cartilaginous after 2 days, later looser and more brittle. Growth at 28° to 30°C rather scant; smooth, soft, glistening, cream-colored smear.

Sabouraud's agar: Excellent growth, spreading, at first flat and smooth, pale straw-yellow, perfectly hard and cartilaginous, later raised and strongly folded, of a loose, curd-like consistency, bright lemon-yellow. Growth at 28° to 30°C only fair, restricted, folded, cream-colored, soon becoming soft and smeary.

Potato: Scant growth; restricted, soft, cream-colored smear.

Broth: Good growth; voluminous, flaky, whitish sediment; broth clear.

Milk: At 28° to 30°C, small cream-colored granules along the tube; the milk undergoes no visible changes within 4 weeks. No proteolytic action.

Indole not formed.

Sucrose is inverted.

Starch is hydrolyzed.

Cellulose is not decomposed.

Nitrates are reduced to nitrites.

No growth in oxygen-free atmosphere.

Nitrogen is utilized as sodium nitrate, ammonium phosphate and asparagine, although these are inferior to peptone as sources of nitrogen.

Source: Fermented beets.

20. **Nocardia flava** (Krassilnikov) *comb. nov.* (*Proactinomyces flavus* Krassilnikov, Bull. Acad. Sci. U. S. S. R., No. 1, 1938, 139.) From Latin *flavus*, yellow.

Cells at first filamentous, 0.7 to 0.8 micron in diameter; after 2 to 3 days broken into long rods and then into cocci 0.7 micron in diameter. No spores, some strains form chlamydospores. Cell multiplication by fission, cross-wall formation, rarely by budding. Cells Gram-positive; not acid-fast.

Gelatin: No liquefaction.

Synthetic agar colonies: Bright yellow or gold color.

Meat peptone media: Dirty yellow pigmentation.

Agar colonies: Pigment bright yellow or gold color on synthetic media, dirty yellow on meat peptone media. Pigment not soluble in medium. Surface of colony somewhat shiny or rough and folded, of a dough-like consistency.

Milk: No peptonization or coagulation.

Sucrose weakly inverted.

Starch is hydrolyzed.

Does not grow on paraffin and wax but makes weak growth on fat.

Habitat: Soil, not common.

21. **Nocardia viridis** (Krassilnikov) *comb. nov.* (*Proactinomyces viridis* Krassilnikov, Bull. Acad. Sci. U. S. S. R., No. 1, 1938, 139). From Latin *viridis*, green.

Mycelial cells often branching, 0.7 to 0.8 micron in diameter with cross-wall; after 5 to 7 days the cells break up into rods 5 to 15 microns long. Cocci not observed. Cells multiply by fission, seldom by budding. Spores not formed. Cells Gram-positive, not acid-fast.

Gelatin: No liquefaction.

Colonies colored dark green. Pigment not soluble in medium, in water or in organic solvents. Surface of colony somewhat shiny. On potato, rough, much folded, broken up into small colonies.

Milk: No peptonization or coagulation.

Sucrose readily inverted.

Starch weakly hydrolyzed.

Grows well on fats and paraffin and less on wax.

Habitat: Soil.

22. **Nocardia citrea** (Krassilnikov) *comb. nov.* (*Proactinomyces citreus* Krassilnikov, Bull. Acad. Sci. U. S. S. R., No. 1, 1938, 139.) From M. L. *citreus*, lemon yellow.

Mycelium in young cultures consists of very fine threads 0.3 to 0.5 micron in diameter. After several days the cells break up into short rods 0.5 by 1.5 to 5 microns and into cocci 0.3 to 0.5 micron in diameter. Multiplies by fission and bud formation; spores not formed. Cells not acid-fast.

Gelatin: Liquefaction.

Colonies: Yellow-green, usually rough and folded.

Milk: Coagulation and peptonization.

Sucrose is inverted.

Starch is hydrolyzed.

Weak growth on fat. No growth on paraffin or wax.

Habitat: Soil and water.

23. **Nocardia madurae** (Vincent) Blanchard. (*Streptothrix madurae* Vincent, Ann. Inst. Past., *8*, 1894, 129; Blanchard, Bouchard's Traité de Path. Gén., *2*, 1896, 868; *Oospora madurae* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 388; *Actinomyces madurae* Lachner-Sandoval, Ueber Strahlenpilze, 1898, 64; *Cladothrix madurae* Macé, Traité Pratique de Bact., 4th.ed., 1901, 1090; *Discomyces madurae* Gedoelst, Champ. Paras. Homme et Animaux, Paris. 1902. 169.) Named for the disease

Madura foot, with which this organism is associated.

Oospora indica Kanthack (Kanthack, Jour. Path. and Bact., *1*, 1893, 140; *Nocardia indica* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 231; *Discomyces indicus* Neveu-Lemaire, Précis de Parasitol. Hum., 5th ed., 1921, 42; *Actinomyces indicus* Brumpt, Précis de Parasitol., Paris, 4th ed., 1927, 1196) is regarded by some authors as identical with *Nocardia madurae* Blanchard. If this is established, then the correct name of the organism is *Nocardia indica* (Kanthack) Chalmers and Christopherson.

The species described under the name *Actinomyces madurae* in previous editions of Bergey's Manual is definitely not the true causative agent of the disease and is probably a contaminant carried as a culture of this species.

Morphology in tissues, growth in form of granules consisting of radiating actinomycosis. In cultures, initial branched mycelium fragmenting into rod-shaped and coccoid bodies. No aerial mycelium or spores. Not acid-fast.

Gelatin: Growth scant, whitish; no liquefaction.

Gelatin colonies: Round, glistening, at first white, then buff to rose or crimson. Pigment production is irregular and unpredictable. Occasionally red soluble pigment is produced. Growth eventually wrinkled. No aerial mycelium.

Potato: Wrinkled friable growth; buff-colored, sometimes red.

Broth: Growth as a floccular sediment.

Milk: No change, or slight slow peptonization.

Diastatic (?) action.

Not pathogenic for the usual laboratory animals; pathogenic for monkeys (Musgrave and Clegg, Philippine Jour. Sci., Ser. B., Med. Sci., *3*, 1908, 470).

Habitat: Cause of some cases of Madura foot.

24. **Nocardia lutea** Christopherson and Archibald. (Christopherson and Archibald, Lancet, *2*, 1918, 847; *Actinomyces luteus* Brumpt, Précis de Parasitol., Paris, 4th ed., 1927, 1206.) From Latin *luteus*, yellow.

Description from Erikson (Med. Res. Council Spec. Rept. Ser. 203, 1935, 30).

Initial elements swollen and segmented, giving rise to irregular spreading polymorphous colonies composed of cells of all shapes and sizes with markedly granular contents. Later more monomorphous, the filaments being arranged in angular apposition. Sometimes (e.g., on synthetic glycerol agar) the segments are so granular as to appear banded. On potato agar, small filamentous colonies are formed with irregular angular branching and bear a few isolated short straight aerial hyphae.

Gelatin: Pale pink wrinkled growth on wall of tube and colorless punctiform and stellate colonies in medium; no liquefaction.

Agar: Abundant, coherent, moist, pink membranous growth with round discrete colonies at margin; after 3 weeks colorless fringed margin, round confluent portion.

Glucose agar: Scant reddish smeary growth.

Glycerol agar: Yellowish-pink, wrinkled membrane.

Potato agar: Coherent pink moist growth, centrally embedded with small round discrete colonies at margin.

Dorset's egg medium: Poor growth, dull pink, spreading.

Serum agar: Confluent granular pink membrane.

Broth: Pink flakes and surface growth.

Inspissated serum: Raised convoluted pink mass; becoming orange, much wrinkled, scalloped margin.

Synthetic sucrose solution: Red granules and abundant minute colorless colonies at bottom; in 2 weeks a colorless dust-like surface pellicle.

Glucose broth: Abundant, pinkish

flaky surface growth, breaking up easily and sinking to bottom.

Litmus milk: Orange-red surface and bottom growth, liquid blue.

Potato plug: Carrot-red, moist, thick, granular growth in bands, partly raised and with discrete round colonies; sparse colorless very thin aerial mycelium at top of slant in 2 months.

Source: From actinomycosis of the lachrymal gland.

25. **Nocardia blackwellii** (Erikson) *comb. nov.* (*Actinomyces blackwellii* Erikson, Med. Res. Counc. Spec. Rept. Ser. 203, 1935, 37.)

Description from Erikson (*loc. cit.*, p. 32).

Initial elements short, rod-like, growing out into longer forms sparsely branching; small radiating colonies are produced with short straight aerial mycelium, frequently large round or ovoid cells are interposed in the irregularly segmented chains of cells, being sometimes isolated in company with 2 or 3 short filaments and sometimes terminal.

Gelatin: Few colorless minute colonies along line of inoculation; after 30 days abundant colorless colonies to 10 mm below surface, larger pink-yellow surface colonies with white aerial mycelium; no liquefaction.

Agar: Confluent wrinkled growth with small, round, pinkish, discrete colonies at margin.

Glucose agar: Abundant, pale pink growth, small conical colonies, piled up, convoluted.

Glycerol agar: Extensive, granular, irregular, thin, pinkish growth; after 40 days, a few discrete colonies with depressed margins, center piled up, pink.

Serum agar: Smooth, cream, umbilicated colonies, with submerged growth extending into medium in scallops 5 to 8 mm deep; a pale pink mass in 2 weeks.

Potato agar: Small, round, colorless colonies covered with white aerial mycelium; after 2 weeks colonies dull pink, submerged margins, few aerial spikes, moderate aerial mycelium at top of slant.

Broth: Flakes, later innumerable minute colonies, some adhering to wall just above liquid level.

Synthetic sucrose solution: Delicate, round, white colonies; later abundant minute colonies in suspension, thick cream pellicle on surface and pink grains in sediment.

Milk: Heavy convoluted bright yellow surface pellicle, no coagulation.

Litmus milk: Yellow surface growth, milky sediment, liquid unchanged.

Carrot plug: Small, round, smooth, cream-colored elevated colonies in 10 days; sparse stiff colorless aerial spikes in 16 days; abundantly piled up, convoluted, ochreous growth in 25 days.

Source: From hock joint of foal.

26. **Nocardia cuniculi** Snijders. (Snijders, Geneesk. Tijdsch. Med. Ind., *64*, 1924, 47 and 75; *Actinomyces cuniculi* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 32; not *Actinomyces cuniculi* Gasperini, Cent. f. Bakt., *15*, 1894, 684; *Actinomyces sumatrae* Erikson, *loc. cit.*, 32.) From Latin *cuniculus*, rabbit.

Description taken from Erikson (*loc. cit.*, p. 31).

Large swollen cells give rise to ramifying filaments or to small chains of short thick segments which branch out into more regular hyphae; sometimes the irregular elements are beset with spiny processes before giving rise to typical long branching filaments; later the picture becomes more monomorphous and short straight aerial hyphae are borne, which presently exhibit irregular segmentation.

Gelatin: Few flakes. No liquefaction.

Agar: Small, round, elevated, cream-colored colonies, umbilicated and radially wrinkled.

Glucose agar: Minute, colorless colon-

ies; becoming dull pink, partly confluent and piled up, few stiff pink aerial spikes.

Glycerol agar: Small round elevated cream-colored colonies, margins depressed; becoming smooth, discrete, yellowish.

Dorset's egg medium: Scant pinkish smeary growth.

Serum agar: Small, raised, cream-colored colonies, becoming confluent and piled up.

Inspissated serum: Thick, colorless, ribbed membrane; no liquefaction.

Broth: Small and larger cream-colored, scale-like surface colonies, abundant, flocculent bottom growth.

Synthetic sucrose solution; Thin surface pellicle, small colorless flakes, minute particles at bottom, scant growth.

Milk: Heavy yellow growth attached to walls; solid coagulum in 1 month.

Litmus milk: Yellow surface growth, liquid unchanged.

Potato plug: Coral-pink, dry, granular growth, covered to a considerable extent with white aerial mycelium, piled up in center, discrete colonies at margin, pink surface pellicle on liquid and colorless colonies at base.

Source: Infected rabbits.

27. **Nocardia rangoonensis** (Erikson) *comb. nov.* (*Actinomyces rangoon* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 37.)

Description from Erikson (*loc. cit.*, p. 33).

Swollen round initial cells, giving rise to branching hyphae which segment and present slipping and angular arrangement; few short straight aerial hyphae, which later develop into a profusely branching long waving aerial mycelium. Non-acid-fast.

Gelatin: Abundant minute colonies in depths and larger cream-colored ones on surface with white aerial mycelium; brown pigment surrounding growth. No liquefaction.

Agar colonies: Round, lobate, umbilicated, raised up, cream-colored to pale pink; later, medium discolored dark brown, colonies colorless.

Glucose agar: Convoluted, coherent, cream-colored growth, medium discolored. After 23 days, wrinkled, biscuit-colored growth, colorless margin, border white aerial mycelium, medium dark brown.

Glycerol agar: Dull, mealy, pink, wrinkled growth, scant white aerial mycelium at top, medium slightly discolored.

Coon's agar: Minute colorless colonies in streaks.

Potato agar: Small, round, lemon-colored colonies, partly confluent, with white aerial mycelium; later medium discolored light brown; submerged growth greenish.

Dorset's egg medium: Extensive colorless growth, pale pink aerial mycelium in center; later covered with a powdery pinkish-white aerial mycelium.

Serum agar colonies: Irregular, small, elevated, cream-colored, frequently umbilicated.

Inspissated serum: Poor growth, small piled up pink mass.

Broth: Abundant colorless growth, flocculent mass at bottom and pellicle at surface, medium slightly discolored.

Synthetic sucrose solution: Small white colonies with pinkish tinge on surface, lesser bottom growth.

Milk: Coagulation, yellow surface ring, becoming partly peptonized, liquid discolored dark brown, brownish growth up side of tube.

Litmus milk: Colorless growth, liquid partly decolorized; coagulation; later partly digested.

Carrot plug: Small round colorless colonies, velvety white aerial mycelium; in 2 months, piled up pink granular mass with warted prominences, marginal zone white aerial mycelium and thin all-over central aerial mycelium.

Source: Human pulmonary case of streptothricosis.

Habitat: Human infections so far as known.

28. **Nocardia caviae** Snijders. (Snidjers, Geneesk. Tijdschr. Ned. Ind., *64*, 1924, 47 and 75; *Actinomyces caviae* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 37.) From the generic name of the guinea pig.

Description from Erikson (*loc. cit.*, p. 32).

Initial segmentation, producing elements of approximately even thickness arranged in angular apposition, and later long profusely ramifying threads with strongly refractile protoplasm. Aerial mycelium straight and branching, the aerial hyphae with occasional coiled tips divided into cylindrical conidia.

Gelatin: A few colorless flakes. No liquefaction.

Glucose agar: Piled up, convoluted, cream-colored to pale pink growth, white aerial mycelium.

Glycerol agar: Scanty growth.

Coon's agar: Colorless scant growth, partly submerged, white aerial mycelium.

Potato agar: Colorless spreading growth with dense white aerial mycelium.

Dorset's egg medium: Heavily corrugated pale pink growth with submerged margin, dense white aerial mycelium in center; after 3 weeks, colorless transpired drops.

Serum agar: Pale pink wrinkled growth, partly submerged; after 4 weeks, piled up with scant white aerial mycelium, medium discolored reddish-brown.

Inspissated serum: Pale pink raised growth, coiled, white aerial mycelium.

Broth: Cream-colored wrinkled surface pellicle extending up wall and breaking easily, moderate bottom growth, flaky, medium discolored.

Synthetic sucrose solution: Round white colonies in suspension and attached to one side of tube, pink surface colonies with white aerial mycelium.

Milk: Colorless surface growth, white aerial mycelium; coagulation.

Litmus milk: Liquid blue, surface growth; after 1 month, white aerial mycelium, colorless sediment, liquid still blue.

Potato plug: Small colorless colonies, white powdery aerial mycelium; later abundant raised pale pink confluent growth, discolored plug; after 2 months, raised buckled pink colonies with white aerial mycelium floating on liquid at base.

Source: Infected guinea pigs, Sumatra.

29. **Nocardia actinomorpha** (Gray and Thornton) *comb. nov.* (*Mycobacterium actinomorphum* Gray and Thornton, Cent. f. Bakt., II Abt., *73*, 1928, 88; *Actinomyces actinomorphus* Bergey et al., Manual, 3rd ed., 1930, 471; *Proactinomyces actinomorphus* Jensen, Proc. Linnean Soc. New So. Wales, *56*, 1931, 363.) From Greek *actis*, ray and Latin *morpha*, shape, form.

Description from Gray and Thornton (*loc. cit.*), Jensen (*loc. cit.*), and Bynoe (Thesis, McGill University, Montreal, 1931).

Long branching filaments and rods: 0.5 to 0.8 by up to 10 microns. In older cultures rods 2 to 3 microns long generally predominate. On some media extentively branching hyphae occur. Readily stained. Not acid-fast. Gram-positive.

Gelatin colonies: After 12 days, round, saucer-like, white, raised rim, edges burred. Liquefaction. Deep colonies: Burrs.

Gelatin stab: After 8 to 14 days, saccate liquefaction, 5 to 8 mm.

Agar colonies: After 11 days, round, 1 mm in diameter, convex, white, granular or resinous; long arborescent processes from the edge. Deep colonies: Arborescent burrs; processes about equal to diameter of colony.

Agar slant: Filiform, raised to convex, white, rugose, dull; edge undulate, with strong tufted projections below surface.

Broth: Turbid, or clear with white scum.

Dorset's egg medium: After 2 weeks, raised, dry, smooth, salmon-buff growth.

Loeffler's medium: After 2 days, smooth, moist, warty, salmon-colored growth.

Litmus milk: Alkaline after 5 to 7 days.

Glycerol potato: After 2 days, dry, wrinkled, pink to orange growth.

Nitrites are produced from nitrates.

No acid from glucose, lactose, sucrose or glycerol.

Phenol and naphthalene are utilized.

Optimum temperature 25° to 30°C.

Optimum pH 7.8 to 8.5.

Distinctive characters: Differs from *Nocardia coeliaca* in saccate liquefaction of gelatin. Long rods and filaments.

Source: A few strains have been isolated from soil in Great Britain and Australia.

Habitat: Presumably soil.

30. **Nocardia flavescens** (Jensen) *comb. nov.* (*Proactinomyces flavescens* Jensen, Proc. Linnean Soc. New So. Wales, *56*, 1931, 361.) From Latin *flavescens*, becoming golden yellow.

On media where a firm growth is produced, the vegetative mycelium appears as long, branched, non-septate hyphae, 0.4 to 0.6 micron thick. In other media, as on nutrient agar and potato, septa are formed and the mycelium appears in preparations as fragments of very variable size, partly resembling highly branched mycobacteria. In several cases—for instance, on nutrient agar at 28° to 30°C, in 5 to 6 weeks old cultures in glucose broth, and in glucose NH_4Cl solution—short elements assume swollen, fusiform to lemon-shaped forms. The aerial mycelium consists of fairly long hyphae of the same thickness as the vegetative hyphae, not very much branched, without spirals, often clinging together in wisps. A differentiation into spores is never visible by direct microscopic examination. Neither is this the case in stained preparations; here the aerial hyphae break up into fragments of quite variable length, from 1.2 to 1.5 up to 10 to 12 microns, showing an irregular, granulated staining.

Gelatin: Slow liquefaction.

Sucrose agar: Good growth. Vegetative mycelium superficially spreading, much raised and wrinkled, cracking, white to cream-colored, of a dry, but loose and crumbly, consistency. Aerial mycelium scant, thin, white. Faint yellow soluble pigment after 2 to 3 weeks.

Glucose agar: Good growth. Vegetative mycelium superficial, wrinkled, honey-yellow, of a hard and cartilaginous consistency. Aerial mycelium thin, smooth, white. Yellow soluble pigment.

Nutrient agar: Good growth. Vegetative mycelium raised and much wrinkled, first dirty cream-colored, later dark yellowish-gray, of a soft, moist, curd-like consistency. No aerial mycelium. No pigment.

Potato: Good to excellent growth. Vegetative mycelium much raised and wrinkled, first cream-colored, later yellowish-brown, soft and smeary. No aerial mycelium, no pigment.

Glucose broth: Rather scant growth. Granulated, yellowish sediment; no surface growth. Broth clear. No pigment. No acidity.

Sucrose is inverted.

Starch is hydrolyzed.

Cellulose is not decomposed.

Nitrates are reduced slightly or not at all with various sources of energy.

Milk: Coagulated and slowly redissolved with acid reaction.

Final reaction in glucose-NH_4Cl solution, pH 3.9 to 3.6.

No growth under anaerobic conditions.

Habitat: Soil.

31. **Nocardia maculata** (Millard and Burr) *comb. nov.* (*Actinomyces maculatus* Millard and Burr, Ann. Appl. Biol., *13*, 1926, 580; *Proactinomyces maculatus* Umbreit, Jour. Bact., *38*, 1939, 84.) From Latin *maculatus*, spotted.

Description taken from Umbreit.

Filamentous organisms possessing a tough shiny colony which is cartilaginous, rarely producing an aerial mycelium, though in certain strains, it may occur frequently. Retains the mycelium form for long periods. Not acid-fast.

Gelatin: Liquefaction.

In the young colony an orange-yellow to orange-red intercellular pigment is produced on all media, which may or may not change to black as the culture ages.

Milk: No digestion.

Starch is hydrolyzed.

Does not utilize paraffin.

Habitat: Soil.

32. **Nocardia rhodnii** (Erikson) *comb. nov.* (*Actinomyces rhodnii* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 37.) Named for the insect genus, *Rhodnius*.

Description from Erikson (*loc. cit.*, p. 29).

In early stages, the minute colonies are composed of hyphal segments arranged in angular apposition; the aerial mycelium being short and straight. Later the growth becomes extensive and spreading, made up partly of long, genuinely branching filaments and partly of short segments exhibiting slipping branching, each giving rise to aerial hyphae. After 2 weeks the angular branching is very marked, delicate spreading herring-bone patterns being formed.

Gelatin: Rapid liquefaction; pale pink colonies in superficial pellicle and sediment.

Coon's agar: Colorless pinpoint colonies.

Czapek's agar: Minute, colorless, round colonies.

Glucose agar: Abundant, coral pink, convoluted, piled up growth.

Glycerol agar: Extensive growth, dull pink colonies round and umbilicated, becoming piled up and deeper coral; later partly submerged.

Dorset's egg medium: Salmon-pink, granular membrane; later piled up.

Serum agar: Extensive, reddish, confluent mass, granular, tending to be piled up; the medium around the growth shows reddish coloration in 2 weeks.

Inspissated serum: Smooth, round, pale pink colonies, centrally depressed and irregularly coiled larger mass; no liquefaction.

Broth: Salmon-pink flakes in sediment and colonies on surface; after 2 weeks abundant growth, discoloration of medium.

Glucose broth: Thin, pink, superficial pellicle, easily breaking up, and small flakes in sediment; after 2 weeks abundant growth extending up tube.

Synthetic sucrose solution: Colorless to pink colonies in superficial pellicle, and minute round white colonies coherent in loosely branching mass in sediment.

Milk: Bright orange growth; medium unchanged.

Potato agar: Abundant, pink growth, piled up, scant stiff white aerial mycelium at top of slant.

Source: From reduvid bug, *Rhodnius prolixus*.

33. **Nocardia gardneri** (Waksman) *comb. nov.* (Actinomycete, Gardner and Chain, Brit. Jour. Exp. Path., *23*, 1942, 123; *Proactinomyces gardneri* Waksman, in Waksman, Horning, Welsch and Woodruff, Soil Sci., *54*, 1942, 289.) Named for Prof. Gardner who first isolated this organism.

Gram-positive, branching mycelium.

Gelatin: Cream-colored surface ring. Rapid liquefaction. Green to greenish-brown soluble pigment gradually diffuses through the liquefied portion.

Nutrient agar: Cream-colored, elevated, lichenoid growth, soft, not leathery; no aerial mycelium; very faint brownish pigment.

Glucose agar: Brownish, lichenoid

growth, with wide, cream-colored edge; white to grayish aerial mycelium gradually covering surface. Reverse of growth yellowish; no soluble pigment.

Glucose-asparagine agar: Aerial mycelium develops slowly.

Tryptone broth: Growth occurs as small pellets at the base of the flask; later, a thin surface pellicle appears, which consists of a branching mycelium. Black pigment slowly produced.

Litmus milk: Unchanged.

Potato: Barnacle-like, brownish, spreading growth; no aerial mycelium. Medium brownish around growth.

Indole not formed.

No acid from glucose, lactose, maltose, mannitol, sucrose and dulcitol.

Good growth at 25°C. Slow growth at 37°C.

Distinctive character: Produces an antibiotic substance (proactinomycin) upon synthetic and organic media which is primarily active against various Gram-positive bacteria.

Source: Isolated as an air contaminant at Oxford, England.

* **Appendix I**: The following species probably belong to this genus. Many are incompletely described. Some of the species listed here may belong in the genus *Streptomyces*.

Actinomyces albus acidus Neukirch. (Neukirch, Inaug. Diss., Strassburg, 1902, 50; *Actinomyces albus* var. *acidus* Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 9.) From a case of keratitis.

Actinomyces avadi Dodge. (*Streptothrix madurae* Koch and Stutzger, Ztschr. f. Hyg., *69*, 1911, 17; not *Streptothrix madurae* Vincent, Ann. Inst. Past., *8*, 1894, 129; Dodge, Medical Mycology, St. Louis, 1935, 729.) From a Madura foot in Egypt, case of Dr. Avad.

Actinomyces bolognesii-chiurcoi (Vuillemin) Dodge. (*Malbrachea bolognesii-chiurcoi* Vuillemin, in Bolognesi and Chiurco, Archivi di Biol., *1*, 1925; Dodge, Medical Mycology, St. Louis, 1935, 766.) From ulcers on the thorax.

Actinomyces cameli (Mason) Sartory and Bailly. (*Streptothrix cameli* Mason, Jour. Trop. Med. and Therap., *32*, 1919, 34; *Oospora cameli* Sartory, Champ. Paras. Homme et Anim., 1923, 822; Sartory and Bailly, Mycoses Pulmonaires, 1923, 253.) From pseudotuberculosis lesions in a camel.

Actinomyces canis (Rabe) Gasperini. (*Discomyces pleuriticus* Vachetta, Studi e ricordi clin. Milano, 1882; *Pleuromyces canis familiaris* Rivolta, Giornali d. Anat. Fisiol. e Patol., *16*, 1884, 4; *Cladothrix canis* Rabe, Berlin. tierärztl. Wochnschr., 1888, 65; Gasperini, Ann. Ist. d'Ig. sper. Univ. Roma, *2*, 1892, 222; *Streptothrix canis* and *Actinomyces pleuriticus canis familiaris*, quoted from Gasperini, Cent. f. Bakt., *15*, 1894, 684; *Leptothrix pleuriticus* Piana and Galli-Vallerio, 1896, quoted from Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 37; *Nocardia canis* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 255; *Oospora canis* Sartory, Champ. Paras. Homme et Anim., 1923, 821.) Rabe isolated this organism in two cases of phlegmon and a case of peritonitis in dogs.

Actinomyces citrocremeus Nannizzi. (*Mycobacterium diphtheriae avium* Trincas, 1907, quoted from Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 50; Nannizzi, *idem*.) From a disease in birds.

Actinomyces dassonvillei Brocq-Rousseu. (Brocq-Rousseu, Thèse Sci.

* The appendix was originally prepared by Prof. S. A. Waksman and Prof. A. T. Henrici, May, 1943; it has been developed further by Mrs. Eleanore Heist Clise, Geneva, New York, August, 1945.

Nat. Paris, 1907; *Nocardia dassonvillei* Liégard and Landrieu, Ann. d'Occulistique, *46*, 1911, 418; *Discomyces dassonvillei* Brumpt, Précis de Parasitologie, Paris, 2nd ed., 1913, 976.) Reported from a cervical abscess (Brumpt), from a case of conjunctivitis (Liégard and Landrieu), and from grain (Pinoy, Bull. Inst. Past., *11*, 1913, 923).

Actinomyces dermatonomus Oxer. (Bull. Austral. Jour. Exp. Biol. Med. Sci., *6*, 1929, 301, quoted from Dodge, Medical Mycology, St. Louis, 1935, 719; Oxer, 1930, quoted from Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 51.) From lesions on sheep in Australia.

Actinomyces donnae Dodge. (*Streptothrix sp.* Donna, Ann. Ig. Sperim., *14*, 1904, 449; Dodge, Medical Mycology, St. Louis, 1935, 745.) From sputum in a pulmonary infection.

Actinomyces dori (Beurmann and Gougerot) Brumpt. (*Sporotrichum*, Dor, Presse Méd., *14*, 1906, 234; *Sporotrichum dori* Beurmann and Gougerot, Ann. Derm. Syphiligr. IV, *7*, 1906, 996; *Discomyces dori* Beurmann and Gougerot, Les Nouvelles Mycoses, 1909, 59; *Rhinocladium dori* Neveu-Lemaire, Précis Parasitol., 1921, 84; *Oospora dori* Sartory, Champ. Paras. Homme et Anim., 1923, 770; Brumpt, Précis de Parasitol., 4th ed., 1927, 1206; *Nocardia dori* Vuillemin, Encyclopédie Mycologique, Paris, *2*, 1931, 284.) Found in subcutaneous abscesses resembling sporotrichosis.

Actinomyces hominis Berestneff. (Berestneff, Inaug. Diss., Moskow, 1897; not *Actinomyces hominis* Waksman, Soil Science, *8*, 1919, 129; *Nocardia hominis* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916; *Discomyces hominis* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 984.) From a case of pseudoactinomycosis.

Actinomyces japonicus Caminiti. (*Streptothrix sp.* Aoyama and Miyamoto, Mitteil. Med. Fak. K. Jap. Univ. Tokio, *4*, 1901, 231; abst. in Cent. f. Bakt., I Abt., Orig., *29*, 1901, 262; Caminiti, Cent. f. Bakt., I Abt., Orig., *44*, 1907, 198; *Streptothrix japonica* Petruschky, in Kolle and Wasserman, Handb. d. path. Mikroorg., 2 Aufl., *5*, 1913, 295; *Discomyces japonicus* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 981.) From a case of actinomycosis of the lungs.

Actinomyces keratolytica Acton and McGuire. (Indian Med. Gaz., *65*, 1930, 61 and *66*, 1931, 65; *Proactinomyces keratolyticus*, author unknown.) Produces cracked heels among the ryots of India.

Actinomyces lepromatis de Souza-Araujo. (Compt. rend. Soc. Biol., *100*, 1929, 937.) From a leproma, Brazil.

Actinomyces levyi Dodge. (*Actinomyces sp.* Levy; *Oospora sp.* Sartory, Champ. Paras. Homme et Anim., 1923, 827; Dodge, Medical Mycology, St. Louis, 1935, 730.) From pus.

Actinomyces micetomae Greco. (*Streptothrix micetomae argentinae β*, Greco, in Durante, Segunda Observación de Pié de Madura o Micetoma en la República Argentina, Thesis, Buenos Aires, 1911; Greco, Origine des Tumeurs, 1916, 759; *Oospora micetomae* Sartory, Champ. Paras. Homme et Anim., 1923, 783.) From a case of mycetoma pedis.

Actinomyces minimus (LeCalve and Malherbe) Dodge. (*Oospora* forme de *Microsporum* (*Audouini* var. *equinum*), Bodin, Arch. de Parasitol., *2*, 1899, 606; *Trichophyton minimum* LeCalve and Malherbe, Arch. de Parasitol.; *Microsporum minimum* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 993; Dodge, Medical Mycology, St. Louis, 1935, 728.) From ringworm of horse and dog.

Actinomyces mucosus Basu. (Indian Med. Gaz., *78*, 1943, 577.) From bronchial actinomycosis.

Actinomyces neddeni Namyslowski. (*Streptothrix sp.* zur Nedden, Klin. Monatsbl. f. Augenheilk., *45*, 1907, 152; Namyslowski, Cent. f. Bakt., I

Abt., Orig., *62*, 1912, 564.) From a case of keratitis.

Actinomyces nodosus (Beveridge) Hagan. (*Fusiformis nodosus* Beveridge, Austral. Council Sci. and Indus. Res. Bul. 140, 1941, 56 pp.; Hagan, The Infectious Diseases of Domestic Animals. Ithaca, New York, 1943, 312.) Considered the primary cause of foot-rot of sheep. Also see *Spirochaeta penortha*.

Actinomyces phenotolerans Werkman. (In Gammel, Arch. Derm. Syphilol., *29*, 1934, 286.) From granuloma in man.

Actinomyces puntonii López Ortega. (López Ortega, Annali d'Igiene, Rome, *44*, 1934, 867; *Asteroides puntonii* Puntoni and Leonardi, Boll. e Atti d. R. Accad. Med. di Roma, *61*, 1935, 94.) From a pulmonary abscess.

Actinomyces purpureus Cavara. (Orloff, Vestnik Ofth., *29*, 1912, 653; Cavara, Micosi Occ., 1928, 99; not *Actinomyces purpureus* Killian and Fehér, Ann. Inst. Past., *55*, 1935, 620.) From a case of keratitis in Russia.

Actinomyces ribeyro Dodge. (*Hongo artrosporado* Ribeyro, Ann. Fac. Med. Lima, *3*, 1919, 1; Dodge, Medical Mycology, St. Louis, 1935, 735.) From a generalized infection on the arms, legs and chest of a patient in Peru.

Actinomyces rodellae Dodge. (*Streptothrix sp.* Rodella, Cent. f. Bakt., I Abt., Orig., *84*, 1920, 450; Dodge, Medical Mycology, St. Louis, 1935, 734.) From abscesses of the tooth and jaw.

Actinomyces ruber (Kruse) Sanfelice. (Un *Cladothrix* cromogeno, Ruiz Casabó, Cronica medico-quirurgica de la Habana, *20*, No. 13, 1894, 340; see Cent. f. Bakt., I Abt., *17*, 1895, 466; *Streptothrix rubra* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 63; *Cladothrix rubra* Macé, Traité Pratique de Bact., 4th ed., 1901, 1097; not *Actinomyces ruber* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; Sanfelice, Cent. f. Bakt., I Abt., Orig., *36*, 1904, 355; *Nocardia rubra* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 265; *Discomyces ruber* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 981.) From sputum. Some authors consider the following synonymous with this organism: *Streptothrix mineacea* (*Actinomyces mineaceus* Lachner-Sandoval, Ueber Strahlenpilze, 1898, 66).

Actinomyces rubidaureus Lachner-Sandoval. (*Cladothrix* mordoré, Thiry, Arch. Physiol. Norm. et Path., *9*, 1897, 283; Lachner-Sandoval, Ueber Strahlenpilze, Inaug. Diss., Strassburg, 1898, 66; *Actinomyces* mordoré, Thiry, Thèse, Nancy, 1900, 82; *Nocardia* mordoré, Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 265; *Nocardia thiryei* de Mello and Pais, Arq. Hig. Pat. Exot., *6*, 1918, 193; *Discomyces thiryi* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 981; *Oospora* mordoré, Sartory, Champ. Paras. Homme et Anim., 1923, 824; *Actinomyces thiryi* Sartory and Bailly, Mycoses Pulmonaires, 1923, 252.) From a case showing anginous exudate with edema.

Actinomyces salvati Langeron. (Langeron, Bull. Soc. Path. Exot., *15*, 1922, 526; Fontoynont and Salvat, *ibid.*, 596.) From generalized nodular lesions in the Madagascar rat.

Actinomyces sartoryi Dodge. (*Oospora pulmonalis* var. acido-resistant, Sartory, Arch. Med. Pharm. Milit., *70*, 1916, 605; Dodge, Medical Mycology, St. Louis, 1935, 756.) From a patient showing symptoms of pulmonary tuberculosis.

Actinomyces septicus MacNeal and Blevins. (Jour. Bact., *49*, 1945, 605.) From human endocarditis.

Actinomyces serratus Dodge. (*Actinomyces asteroides* var. *serratus* Sartory, Meyer and Meyer, Ann. Inst. Past., *44*, 1930, 298; also see Compt. rend. Acad. Sci. Paris, *188*, 1929, 745; Dodge, Medical Mycology, St. Louis, 1935, 745.) From a case of actinomycosis of bones with yellow grains.

Actinomyces sommeri Greco. (*Streptothrix madurae* Greco, Primer Caso de

Pié de Madura o Micetoma en la República Argentina, Thesis, Buenos Aires, 1904; *Streptothrix micetomas argentinae* α, Greco, in Durante, Segunda Observación de Pié de Madura o Micetomá en la República Argentina, Thesis, Buenos Aires, 1911; Greco, Origine des Tumeurs, 1916, 726; *Nocardia micetomae-argentinae* Durant, 1911, quoted from Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 985; *Oospora sommeri* Sartory, Champ. Paras. Homme et Anim., 1923, 783.) From a case of mycetoma pedis in Argentina.

Actinomyces tossicus Dodge. (*Actinomyces albus* var. *tossica* Rossi, Ann. Ig. Sperim., *9*, 1905, 693; *Oospora alba* var. toxique, Sartory, Champ. Paras. Homme et Anim., 1923, 829; Dodge, Medical Mycology, St. Louis, 1935, 719.) From tumors in the abdominal cavities of domestic fowl.

Actinomyces urethridis Brumpt. (Précis de Parasitol., Paris, 4th ed., 1927, 1206.) Isolated by Roček in 1920 from cases of prostatitis.

Actinomyces variabilis Cohn. (Cent. f. Bakt., I Abt., Orig., *70*, 1913, 301.) From pus in the bladder in a case of cystitis and from the prostate.

Asteroides pseudocarneus Puntoni and Leonardi. (Boll. e Atti d. R. Accad. Med. di Roma, *61*, 1935, 93.)

Bacillus berestnewi Lepeschkin. (Cent. f. Bakt., II Abt., *12*, 1904, 641 and *13*, 1904, 13.) From sputum of a pneumonia patient.

Bacillus (*Micrococcus?*) *havaniensis* Sternberg. (Sternberg, Manual of Bact., 1893, 718; *Bacterium havaniensis* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., *9*, 1897, 116; *Serratia havaniensis* Bergey et al., Manual, 1st ed., 1923, 95.) From human intestinal canal.

Cladothrix matruchoti Mendel. (Mendel, Compt. rend. Soc. Biol., *82*, 1919, 583; *Nocardia matruchoti* Pettit, 1921, quoted from Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 51; *Oospora matruchoti*, quoted from Nannizzi, *idem*; *Actinomyces matruchoti* Nannizzi, *idem*.) From the roots of a decaying tooth with tumefaction. Species dubia.

Cohnistrepothrix misri Carpano. (Riv. di Parassitologia, n. 2, p. 107; quoted from Boll. d. Sez. Ital. d. Soc. Internat. d. Microbiol., *10*, 1938, 62.) From human dermatosis in Egypt.

Discomyces berardinisi Brumpt. (*Streptothrix sp.* de Berardinis, Ann. Ottalmol. Lavori Clin. Oculist. Napoli, *33*, 1904, 914; Actinomyces de Berardinis, Namyslowski, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 566; Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 977; *Actinomyces bernardinisi* Brumpt, *ibid.*, 4th ed., 1927, 1189; *Nocardia berardinisi* Vuillemin, Encyclopédie Mycologique, Paris, *2*, 1931, 126.) From a case of keratitis.

Discomyces brasiliensis Lindenberg. (Lindenberg, Rev. med. de S. Paolo, 1909, No. 18, and Arch. de Parasitol., *13*, 1909, 265; *Nocardia brasiliensis* Pinoy, Bull. Inst. Past., Paris, *11*, 1913, 936; *Streptothrix brasiliensis* Greco, Origine des Tumeurs, 1916, 724; *Oospora brasiliensis* Sartory, Champ. Paras. Homme et Anim., 1923, 786; *Actinomyces brasiliensis* Gomes, Ann. Palistas Med. Cirurg., *14*, 1923, 150.) From a case of mycetoma of the leg. According to Pinoy and others, idential with *Nocardia asteroides*.

Discomyces congolensis Baerts. (Baerts, Bull. Méd. Katanga, *2*, 1925, 67; *Actinomyces congolensis* Brumpt, Précis de Parasitol., Paris, 4th ed., 1927, 1206.) From lesions in a case of actinomycosis from the Belgian Congo.

Discomyces dispar (Vidal) Brumpt. (*Microsporon dispar* Vidal, 1882, *Microsporon anemoeon* Vidal, 1882 and *Sporotrichum dispar*, quoted from Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 995 and from Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 25; Brumpt, *idem*; *Actinomyces dispar* Brumpt, *ibid.*, 4th ed., 1927, 1206.)

From a case of pityriasis. Species dubia.

Discomyces mexicanus Boyd and Crutchfield. (Boyd and Crutchfield, Amer. Jour. Trop. Med., *1*, 1921, 268; *Actinomyces mexicanus* Brumpt, Précis de Parasitol., Paris, 4th ed., 1927, 1192; *Nocardia mexicana* Ota, Jap. Jour. Derm. Urol., *28*, 1928.) From a mycetoma of the foot.

Discomyces minutissimus (Burchardt) Brumpt. (*Microsporon minutissimum* Burchardt, in Uhle and Wagn. Pat. Gen., 1859; *Trichothecium sp.* J. Neumann, 1868; *Microsporon gracile* Balzer, Ann. Derm. Syphiligr., II, *4*, 1883, 681; *Sporotrichum minutissimum* Saccardo, Sylloge Fungorum, *4*, 1886, 100; *Microsporoides minutissimus* Neveu-Lemaire, Précis Parasitol., 1906; Brumpt, Précis de Parasitol., 1st ed., 1910, 863; *Oospora minutissima* Ridet, Oospora et Oosporoses, 1911, 68; *Nocardia minutissima* Verdun, Précis parasitol., 1912; *Actinomyces minutissimus* Brumpt, *ibid.*, 4th ed., 1927, 1199.) Reported as the etiological agent of erythrasma.

Mycobacterium alluvialum Bergey et al. (Kersten, Cent. f. Bakt., I Abt., Orig., *51*, 1909, 494; Bergey et al., Manual, 1st ed., 1923, 379.) From soil.

Mycobacterium convolutum Gray and Thornton. (Gray and Thornton, Cent. f. Bakt., II Abt., *73*, 1928, 87; *Actinomyces convolutus* Bergey et al., Manual, 3rd ed., 1930, 473.) From soil. Resembles *Nocardia opaca*.

Nocardia arborescens (Edington) Trevisan. (*Bacillus arborescens* Edington, Brit. Med. Jour., June 11, 1887, 1262; Trevisan, I generi e le specie delle Batteriacee, 1889, 9; *Actinomyces arborescens* Gasperini, Cent. f. Bakt., *15*, 1894, 684.) From human skin in cases of scarlatina.

Nocardia bahiensis da Silva. (Da Silva, Brasil Med., *33*, 1919, 81 and Mem. Inst. Butantan, *1*, 1918–1919, 187; *Discomyces bahiensis* Neveu-Lemaire, Précis de Parasitol. Hum., 5th ed., 1921, 44; *Oospora bahiensis* Sartory, Champ. Paras. Homme et Anim., 1923, 784; *Actinomyces bahiensis* Brumpt, Précis de Parasitol., 4th ed., 1927, 1195.) From an actinomycotic mycetoma in Brazil.

Nocardia berestneffi Chalmers and Christopherson. (Streptothrix cas I, II, Berestneff, Inaug. Diss., Moscow, 1897; Chalmers and Christopherson, Ann. Trop. Med. and Parasitol., *10*, 1916, 263; *Discomyces berestneffi* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 992; *Actinomyces berestneffi* Sartory and Bailly, Mycoses pulmonaires, 1923, 256.) From a case of pulmonary pseudotuberculosis.

Nocardia bicolor (Trolldenier) de Mello and Fernandes. (*Actinomyces bicolor* Trolldenier, Ztschr. f. Tiermedizin, *7*, 1903, 81; de Mello and Fernandes, Mem. Asiatic Soc. Bengal, *7*, 1919, 106.) Found in cerebromeningitis, bronchitis and lymphadenitis in a dog.

Nocardia convoluta Chalmers and Christopherson. (Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 257; *Discomyces convolutus* Neveu-Lemaire, Précis Parasitol. Hum., 5th ed., 1921, 44; *Oospora convoluta* Sartory, Champ. Paras. Homme et Anim., 1923, 769; *Actinomyces convolutus* Brumpt, Précis de Parasitol., Paris, 4th ed., 1927, 1195.) From a yellow grain mycetoma of the foot in the Sudan.

Nocardia cylindracea de Korté. (De Korté, Ann. Trop. Med. Parasit., *11*, 1918, 205; *Discomyces cylindraceus* Neveu-Lemaire, Précis Parasitol. Hum., 5th ed., 1921, 44; *Oospora cylindracea* Sartory, Champ. Paras. Homme et Anim., 1923, 774; *Actinomyces cylindraceus* Brumpt, Précis de Parasitologie, Paris, 4th ed., 1927, 1206.) From an infection of the outer ear, resembling mycetoma.

Nocardia enteritidis (Pottien) Castellani and Chalmers. (*Streptothrix enteritidis* Pottien, 1902, according to Sanfelice, Cent. f. Bakt., I Abt., Orig., *36*,

1904, 357; *Bacillus enteritidis* Pottien, 1902, according to Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 25; not *Bacillus enteritidis* Gaertner, Correspond. d. Allgemein. Artz. Vereins Thuringen, *17*, 1888, 573; Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 819; *Oospora enteritidis*, quoted from Nannizzi, *loc. cit.*; *Discomyces enteritidis* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 980; *Actinomyces enteritidis* Brumpt, *ibid.*, 4th ed., 1927, 1191.) From a case of enteritis.

Nocardia equi Chalmers and Christopherson. (*Streptothrix sp.* Dean, Trans. Path. Soc. London, *51*, 1900, 26; Chalmers and Christopherson, Ann. Trop. Med. Parasit., *10*, 1916, 263; *Discomcyes equi* Brumpt, Précis de Parasitologie, 3rd ed., 1922, 992; *Actinomyces equi* Sartory and Bailly, Mycoses Pulmonaires, 1923, 256.) From an abscess on the jaw of a horse.

Nocardia erythrea (Foulerton) Chalmers and Christopherson. (*Streptothrix erythrea* Foulerton, 1910; Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 268.)

Nocardia foulertoni Chalmers and Christopherson. (*Streptothrix hominis* Foulerton and Jones, Trans. Path. Soc. London, *53*, 1902, 56; *Streptothrix hominis I* Foulerton, in Allbutt and Rolleston, Syst. of Medicine, *2*, 1906, 302; *Nocardia hominis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 819; *Oospora hominis* Ridet, 1911, according to Castellani and Chalmers, *idem*; Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 263; *Discomyces foulertoni* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 993; *Actinomyces foulertoni* Brumpt, *ibid.*, 4th ed., 1927, 1204.) From abscesses of the chest and from sputum.

Nocardia genesii Fróes. (Fróes, Do mycetoma pedis no Brasil 50, 1930; *Actinomyces genesii* Dodge, Medical Mycology, St. Louis, 1935, 761.) From a case of Genesio Salles from Bahia.

Nocardia jollyi Vuillemin. (Vuillemin, in Jolly, Rev. Med. de l'Est, *48* 1920, 42; *Discomyces jollyi* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 84; *Oospora jollyi* Sartory, Champ. Paras. Homme et Anim., 1923, 770; *Actinomyces jollyi* Brumpt, *ibid.*, 4th ed., 1927, 1196.) From a case clinically resembling bubonic plague.

Nocardia lasserei Verdun. (*Nocardia sp.* Lasserre, Thèse Toulouse, 1904; Verdun, Précis Parasitol., 1912; *Discomyces lasserrei* Neveu-Lemaire, Précis Parasitol. Hum., 5th ed., 1921, 43; *Oospora lasserei* Sartory, Champ. Paras. Homme et Anim., 1923, 798, *Actinomyces lasserei* Brumpt, Précis de Parasitol., 4th ed., 1927, 1206.) From an ulcerative lesion on the pharynx and upper lip.

Nocardia lingualis (Eisenberg) Chalmers and Christopherson. (Zungenbelag-Vibrio, Weibel, Cent. f. Bakt., *4*, 1888, 227; *Vibrio lingualis* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 212; *Spirillum linguae* Sternberg, Man. of Bact., 1893, 697; *Spirosoma lingualis* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., *1*, la, 1895, 31; *Streptothrix lingualis* Bajardi, Cent. f. Bakt., I Abt., Orig., *35*, 1904, 129; Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 265; not *Nocardia lingualis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 819; *Discomyces lingualis* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 980; *Actinomyces lingualis* Sartory and Bailly, Mycoses Pulmonaires, 1923, 252.) From a deposit on the tongue. Jensen (Proc. Linn. Soc. New So. Wales, *59*, 1934, 43) regards this species as closely related to *Corynebacterium filamentosum*. Also see page 205.

Nocardia londinensis (sic) Chalmers and Christopherson. (*Streptothrix hominis II*, Foulerton, Lancet, *1*, 1906, 970; Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 256; *Discomyces londinensis* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 993; *Actinomyces londinensis* Brumpt, *ibid.*,

4th ed., 1927, 1204.) From cases of human actinomycosis.

Nocardia macrodipodidarum Fox. (Fox, Disease in Captive Wild Mammals and Birds, 1923, 570; *Actinomyces macrodipodidarum* Dodge, Medical Mycology, St. Louis, 1935, 747.) Found in lumpy jaw with septicemia and gasteroenteritis of kangaroos.

Nocardia nicollei Delanoë. (Delanoë, Arch. Inst. Past. Tunis, *17*, 1928, 257; *Actinomyces nicollei* Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 36.) From a mycetoma of the thigh.

Nocardia nigra (Castellani) Castellani and Chalmers. (*Streptothrix nigra* Castellani, 1913, according to Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 1062; presumably not *Streptothrix nigra* Rossi Doria, Ann. Ist. Ig. sper. Univ. Roma, *1*, 1891, 399; Castellani and Chalmers, *idem.*) From black granules in a case of tonsillar nocardiomycosis. Usually forms black colonies on agar.

Nocardia panginensis de Mello and Fernandes. (De Mello and Fernandes, Mem. Asiatic Soc. Bengal, *7*, 1919, 130; *Actinomyces panginensis* Dodge, Medical Mycology, St. Louis, 1935, 718.) From a dermatosis.

Nocardia pijperi Castellani and Chalmers. (*Nocardia sp.* Pijper, Folia Microbiol., *5*, 1917, 50 and Med. Jour. So. Africa, *12*, 1917, 141; Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 1060; *Discomyces pijperi* Neveu-Lemaire, Précis Parasitol. Hum., 5th ed., 1921, 44; *Actinomyces pijperi* Sartory and Bailly, Mycoses pulmonaires, 1923, 256.) From sputum in a case of chronic bronchitis.

Nocardia pinoyi de Mello and Fernandes. (De Mello and Fernandes, Mem. Asiatic Soc. Bengal, *7*, 1919, 130; *Actinomyces pinoyi* Dodge, Medical Mycology, St. Louis, 1935, 723.) From a case of erythrasma.

Nocardia ponceti Verdun. (Verdun, Précis Parasitol., 1912; *Discomyces ponceti* Neveu-Lemaire, Précis Parasitol. Hum., 5th ed., 1921, 43; *Oospora ponceti* Sartory, Champ. Paras. Homme et Anim., 1923, 778; *Actinomyces ponceti* Brumpt, Précis de Parasit., Paris, 4th ed., 1927, 1205.) Isolated by Moorhof, Dor and Poncet from a muscular pseudo-actinomycosis. This species may be synonymous with *Nocardia krausei* (Chester).

Nocardia putridogenes (Vezspremi) de Mello and Pais. (*Cladothrix putridogenes* Vezspremi, Cent. f. Bakt., I Abt., *44*, 1907, 408 and 515; de Mello and Pais, Arq. Hig. Pat. Exot., *6*, 1918, 187; *Oospora putridogenes* Sartory, Champ. Paras. Homme et Anim., 1923, 823; *Actinomyces putridogenes* Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 41.) From greenish pus from gingival ulcers and abscess of the jaw.

Nocardia repens (Eklund) Vuillemin. (*Epidermophyton sp.* Lang, 1879; *Lepocolla repens* Eklund, 1883; *Achorion repens* Guéguen, 1904; *Epidermophyton repens*; all quoted from Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934; Vuillemin, Encyclopédie Mycologique, Paris, *2*, 1931, 124; *Actinomyces repens* Nannizzi, *idem.*) From the skin in cases of psoriasis.

Nocardia rivierei Verdun. (*Streptothrix sp.* Rivière, Cong. Franç. Méd. Bordeaux 1895, *2*, 1896, 1003; *Actinomyces* Sabrazes et Rivieri, Berestnev, Inaug. Diss., Moscow, 1897; Verdun, Précis Parasitol., 1912; *Discomyces rivierei* Neveu-Lemaire, Précis Parasitol. Hum., 5th ed., 1921, 43; *Oospora rivierei* Sartory, Champ. Paras. Homme et Anim., 1923, 792; *Actinomyces rivierei* Brumpt, Précis de Parasitol., 4th ed., 1927, 1201.) From sputum and pus in a bronchopleuropulmonary infection followed by multiple abscesses.

Nocardia sanfelicei Redaelli. (Streptothrix acido-resistente, Sanfelice, Boll. Ist. Sieroterapico Milanese, *2*, 1922, 327; Redaelli, Ist. Sieroterapico Milanese, *7*, 1928, 75 and 121; *Actinomyces*

sanfelicei Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 51.) From fatal lesions in a rat.

Nocardia splenica Gibson. (Gibson, 1930, quoted from Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 50; *Actinomyces splenica* Nannizzi, *idem.*) From a case of splenomegalia.

Nocardia tenuis Castellani. (Castellani, Brit. Jour. Derm. Syphilis, *23*, 1911, 341; *Discomyces tenuis* Castellani, Proc. Roy. Soc. Med., *6*, Derm., 1912, 23; *Cohnistreptothrix tenuis* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 273; *Actinomyces tenuis* Dodge, Medical Mycology, St. Louis, 1935, 715.) From cases of trichomycosis flava.

Nocardia valvulae Chalmers and Christopherson. (*Streptothrix valvulae destruens bovis* Luginger, Monats. f. prakt. Tierheilk., *15*, 1904, 289; Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 263; *Oospora valvulae destruens bovis* Sartory, Champ. Paras. Homme et Anim., 1923, 788; *Actinomyces valvularis* Ford, Textb. of Bact., 1927, 211; *Actinomyces valvulae* Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 51.) From endocarditis in cattle.

Oospora anaerobies Sartory. (*Actinomyces sp.* Butterfield, Jour. Inf. Dis., *2*, 1905, 421; Sartory, Champ. Parasit. Homme et Anim., 1923, 830; *Actinomyces anaerobies* Plaut, quoted from Dodge, Medical Mycology, St. Louis, 1935, 717.) From pus from human lung.

Oospora bronchialis Sartory and Levasseur. (Sartory and Levasseur, 1914, quoted from Neveu-Lemaire, Précis Parasitol. Hum., 5th ed., 1921, 43; *Actinomyces bronchialis* Sartory, Bull. Sci. Pharm., *23*, 1916, 12; *Discomyces bronchialis* Neveu-Lemaire, *idem.*) From sputum in a case of pulmonary oosporosis.

Oospora buccalis Roger, Bory and Sartory. (Roger, Bory and Sartory, Bull. Mem. Soc. Méd. Hôp. Paris, *27*, 1909, 319 and Compt. rend. Soc. Biol., *66*, 1909, 301; *Discomyces buccalis* Brumpt, Précis de Parasitol., Paris, 1st ed., 1910, 861; *Nocardia buccalis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 819; *Actinomyces buccalis* Sartory and Bailly, Mycoses pulmonaires, 1923, 256.) From a case of creamy stomatitis with tonsillar abscess.

Oospora catarrhalis Sartory and Bailly. (Sartory and Bailly, Thèse Univ. Strasbourg Fac. Pharm., *4*, 1921, 57; *Discomyces catarrhalis* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 984; *Actinomyces catarrhalis* Brumpt, *ibid.*, 4th ed., 1927, 1195.) From sputum in a case of pulmonary oosporosis.

Oospora hominis Ridet. (*Streptothrix hominis IV* Foulerton, 1906; *Streptothrix hominis III* Foulerton, 1910; Ridet, 1911, according to Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 9; *Nocardia appendicis* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 256; *Discomyces appendicis* Brumpt, Précis de Parasitol., 3rd ed., 1922, 977; *Actinomyces appendicis* Brumpt, *ibid.*, 4th ed., 1927, 1189.) From a case of appendicitis and an iliac abscess.

Oospora lingualis Guéguen. (Guéguen, Compt. rend. Soc. Biol., *64*, 1908, 852; *Discomyces lingualis* Brumpt, Précis de Parasitol., Paris, 1st ed., 1910, 865 and 2nd ed., 1913, 976; not *Discomyces lingualis* Brumpt, *ibid.*, 3rd ed., 1922, 980; *Nocardia lingualis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 819; not *Nocardia lingualis* Chalmers and Christopherson, Ann. Trop. Med. and Parasitol., *10*, 1916, 265; *Discomyces gueguení* Brumpt, *ibid.*, 3rd ed., 1922, 980; *Actinomyces gueguení* Brumpt, *ibid.*, 4th ed., 1927, 1191; *Nocardia gueguení* Ota, Jap. Jour. Derm Urol., *28*, 1928.) From cases of lingua nigra.

Oospora pulmonalis Roger, Sartory and Bory. (Roger, Sartory and Bory, Compt. rend. Soc. Biol., *66*, 1909, 150; *Discomyces pulmonalis* Brumpt, Précis

de Parasitologie, 1st ed., 1910, 860; *Nocardia pulmonalis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 817; *Actinomyces pulmonalis* Sartory and Bailly, Mycoses Pulmonaires, 1923, 256.) From the sputum of a patient with pulmonary mycosis.

Oospora pulmonalis var. *chromogena* Sartory. (Sartory, 1913; *Actinomyces pulmonalis* var. *chromogenus* Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 39.) From sputum of a patient suspected of having pulmonary tuberculosis.

Proactinomyces albus Krassilnikov. (Bull. Acad. Sci., U. S. S. R., No. 1, 1938, 139.) Cells at first produce mycelium with frequent branching varying in diameter from 0.6 to 1.0 micron. Breaks up after 2 or 3 days into rods and sometimes later into cocci. Multiply by fission, cross-wall formation and budding. Does not form spores; cells are Gram-positive and are not acid-fast. Colorless growth. Colonies vary in the different strains, somewhat rough, folded, shiny or dull, of a dough-like consistency. Krassilnikov listed several strains of this organism, including *Proactinomyces oligocarbophilus*.

Proactinomyces aquosus Turfitt. (Jour. Bact., *47*, 1944, 490.) From soil. Decomposes cholesterol.

Proactinomyces cyaneus (Beijerinck) Krassilnikov. (*Actinococcus cyaneus* Beijerinck, Folia microbiol., Delft, *2*, 1914, 196; Krassilnikov, *loc. cit.*) Blue pigment produced on synthetic media. Cells are rod-shaped. 0.7 to 0.8 by 3 to 7 microns. Branching cell material on potato multiplies by means of bud formation, by fission, and cross-wall formation; no true spores formed.

Proactinomyces cyaneus-antibioticus Gause. (Jour. Bact., *51*, 1946, 649.) From soil. Produces litmocidin, a new antibiotic.

Proactinomyces moormani Franklin. (Ann. Intern. Med., *13*, 1940, 1205.) From the pus of multiple molar abscesses in a dental patient.

Proactinomyces paraguayensis Almeida. (Mycopath., *2*, 1940, 201.) From a thoracic mycetoma with heavy, dark grains affecting a Canadian patient living in the Paraguayan Chaco. Sabouraud's glucose agar: Pseudomembranous colony with raised, dark center surrounded by a white band, progressively increasing in size, and then by a light chocolate area.

Proactinomyces restrictus Turfitt. (Jour. Bact., *47*, 1944, 491.) From soil. Decomposes cholesterol.

Proactinomyces sp. Helzer. Found in sputum of tuberculous patient. Pathogenic for guinea pigs and rabbits.

Streptothrix buccalis Goadby. (Mycology of the Mouth, London, 1903, 200.) From the mouth in cases of pyorrhoea. Chalmers and Christopherson (Ann. Trop. Med. and Parasit., *10*, 1916, 234) regard this as a synonym of *Nocardia liquefaciens*.

Streptothrix flava Chester. (*Actinomyces sp.* Bruns, Cent. f. Bakt., *26*, 1899, 11; Chester, Man. Determ. Bact., 1901, 362; *Nocardia bruni* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 256; *Streptothrix hominis* Bruns, according to Chalmers and Christopherson, *idem*; *Discomyces bruni* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 992; *Actinomyces bruni* Brumpt, *ibid.*, 4th ed., 1927, 1204; *Actinomyces flavus* Dodge, Medical Mycology, St. Louis, 1935, 752.) From pus from a case of actinomycosis of the abdominal wall.

Streptothrix fusca Karwacki. (Karwacki, Compt. rend. Soc. Biol., *66*, 1911, 180; not *Streptothrix fusca* Corda, Prachtflora europäischer Schimmelbildungen, Leipzig and Dresden, 1839, 27; *Nocardia fusca* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 818; *Discomyces fuscus* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 993; *Oospora fusca* Sartory, Champ. Paras.

Homme et Anim., 1923, 809; *Actinomyces fuscus* Sartory and Bailly, Mycoses pulmonaires, 1923, 256; not *Actinomyces fusca* Söhngen and Fol, Cent. f. Bakt., II Abt., *40*, 1914, 87.) From the sputum of a tuberculosis patient.

Streptothrix luteola Foulerton and Jones. (Foulerton and Jones, Trans. Path. Soc. London, *53*, 1902, 75; also see Foulerton, Lancet, *1*, 1905, 1200 and *1*, 1906, 970; *Nocardia luteola* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 818; *Discomyces luteolus* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 981; *Oospora luteola* Sartory, Champ. Paras. Homme et Anim., 1923, 812; *Actinomyces luteolus* Ford, Textb. of Bact., 1927, 213.) From a lung infection, from a case of conjunctivitis, and from a dental abscess.

Streptothrix madurae Solari. (Solari, Semana Méd., *24*, 1917, 573; not *Streptothrix madurae* Vincent, Ann. Inst. Past., *8*, 1894, 129; not *Streptothrix madurae* Koch and Stutzger, Ztschr. f. Hyg., *69*, 1911, 17.) From Madura foot. See *Actinomyces avadi*.

Streptothrix muris-ratti Schottmüller. (Schottmüller, Derm. Wochnschr., *58*, 1914, 77; *Nocardia muris* de Mello and Pais, Arq. Hig. Pat. Exot., *6*, 1918, 183; *Actinomyces muris-ratti* Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 51.) From sodoku or rat-bite fever.

Streptothrix tarozzii Miescher. (*Actinomyces albus* Tarozzi, Archivio Sci. Med., *33*, 1909, 553; Miescher, Arch. Derm. Syphilis, *124*, 1917, 297; *Actinomyces tarozzii* Dodge, Medical Mycology, St. Louis, 1935, 735.) From a case of Madura foot.

Streptothrix verrucosa (Adler) Miescher. (*Actinomyces verrucosus* Adler, 1904, see Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 46; Miescher, Arch. Derm. Syphilis, *124*, 1917, 314.) From mycetoma pedis.

Genus II. Actinomyces *Harz.*

(Harz, in Bollinger, Centbl. f. med. Wissensch., *15*, 1877, 485; Harz, Jahresber. d. Münch. Thierarzneischule for 1877–78, 1879, 125; not *Actinomyce* Meyen, Linnaea, *2*, 1827, 442; *Discomyces* Rivolta, Clinica Veter., Milano, *1*, 1878, 208; *Actinocladothrix* Afanasiev, St. Petersb. med. Wchnschr., *4*, 1887, 323; *Micromyces* Gruber, Cent. f. Bakt., *10*, 1891, 648; not *Micromyces* Dangeard, Le Botaniste, *1*, 1888, 55; *Actinobacterium* Haas, Cent. f. Bakt., I Abt., Orig., *40*, 1906, 180; *Carteria* and *Carterii* Musgrave, Clegg and Polk, Philippine Jour. Sci., Ser. B, Med. Sci., *3*, 1908, 470; *Cohnistreptothrix* Pinoy (in part), 1911, see Pinoy, Bull. Inst. Past., *11*, 1913, 929; *Anaeromyces* Castellani, Douglas and Thomson, Jour. Trop. Med. Hyg., *24*, 1921, 149; *Brevistreptothrix* Lignières, Ann. Parasit. Hum. Comp., *2*, 1924, 1.)

True mycelium produced. The vegetative mycelium fragments into elements of irregular size and may exhibit angular branching. No conidia produced. Not acid-fast. Anaerobic to microaerophilic. Pathogenic for man and animals.

The type species is *Actinomyces bovis* Harz.

Key to the species of genus Actinomyces.

I. Colonies soft, smooth, uniform, not adherent to medium. No aerial hyphae.
   1. *Actinomyces bovis.*

II. Colonies tougher in texture and warted in appearance, adherent to medium. Scanty aerial growth of hyphae.
   2. *Actinomyces israeli.*

1. **Actinomyces bovis** Harz. (Harz, in Bollinger, Cent. f. med. Wissensch., *15*, 1877, 485; Jahrb. d. Münch. Thierarzeneischule, 1877, 781; *Discomyces bovis* Rivolta, La clinica Veterinaria, *1*, 1878, 169 or 208; *Bacterium actinocladothrix* Afanasiev, St. Petersburger Med. Wochnschr., *13*, 1888, 84; *Nocardia actinomyces* Trevisan, I generi e le specie delle Batteriacee, Milan, 1889, 9; *Streptotrix actinomyces* Rossi Doria, Ann. d. Ist. d'Igi. Sper., Univ. di Roma, *1*, 1891, 425; *Cladothrix bovis* Macé, Traité de Bact., 2nd ed., 1891, 666; *Oospora bovis* Sauvageau and Radais, Ann. Inst. Past., Paris, *6*, 1892, 271; *Actinomyces bovis sulphureus* Gasperini, Cent. f. Bakt., *15*, 1894, 684; *Nocardia bovis* Blanchard, in Bouchard, Traité de Path. Générale, *2*, 1896, 857; *Actinomyces sulphureus* Gasperini, Atti Soc. Tosc. Scienz. Nat., P. V., *11*, 1896; *Cladothrix actinomyces* Macé, Traité de Bact., 3rd ed., 1897, 1038; *Streptothrix actinomycotica* Foulerton, Lancet, *2*, 1899, 780; *Streptothrix bovis communis* Foulerton, Jour. Comp. Path. and Therap., *14*, 1901, 50; *Streptothrix bovis* Chester, Man. Determ Bact., 1901, 361; *Streptothrix sulphurea* Caminiti, Cent. f. Bakt., I Abt., Orig., *44*, 1907, 197; *Sphaerotilus bovis* Engler, Syllabus der Pflanzenfam., 5 Aufl., 1907, 5; *Nocardia sulphurea* Vuillemin, Encyclopédie Mycologique, Paris, *2*, 1931, 129; *Proactinomyces bovis* Henrici, Biology of Bact., 2nd ed., 1939, 409.) From Latin *bovis*, of the ox.

Synonyms previous to 1919 as given by Breed and Conn, Jour. Bact., *4*, 1919, 596.

Probable synonym: *Brevistreptothrix spitzi* Lignières, Annales de Parasit., *2*, 1924, 2 (*Streptothrix spitzi* Lignières and Spitz, Cent. f. Bakt., I Abt., Orig., *35*, 1904, 453; *Actinobacterium isreali* var. *spitzi* Sampietro, Ann. Igiene, *18*, 1908, 391; *Discomyces spitzi* Brumpt, Précis de Parasitol., Paris, 1st ed., 1910, 847; *Actinomyces spitzi* Lieske, Morphol. u. Biol. d. Strahlenpilze, Leipzig, 1921, 32; *Oospora spitzi* Sartory, Champ. Paras. Homme et Anim., 1923, 775). Found in mycosis of the upper jaw of oxen in Argentina.

Description from Erikson, Med. Res. Council, London, Special Report Ser. 240, 1940, 63 pp.

No aerial hyphae. Radiate, sulfur-colored granules occur in the pus found in cases of actinomycosis. Large club-shaped hyphae are seen in morbid tissues. Gram-positive. Non-motile. Not acid-fast.

Mycelium: Undergoes fragmentation very rapidly, extensive branching is rare. Hyphae less than 1 micron in diameter.

Colonies: Smoother and softer in consistency, and more uniform than in the following species. The colonies are not adherent to the medium and growth is scantier.

Semi-solid media: Excellent growth, especially with paraffin seal.

Gelatin: Occasionally scant, flaky growth. No liquefaction.

Liquid media: Occasional turbidity with a light flocculent growth.

Acid from glucose, sucrose and maltose. No acid from salicin and mannitol.

Pigments: No soluble pigments produced on protein media. No insoluble pigments produced by growth.

Egg or serum media: No proteolytic action.

Litmus milk: Becomes acid but usually no coagulation, no peptonization. Sometimes no growth.

No hemolysis in blood broth or blood agar.

Serology: No cross agglutination between five bovine strains and human strains of *Actinomyces israeli*. No cross reactions with representative aerobic strains.

Optimum temperature 37°C.

Anaerobic to microaerophilic. Bovine strains are more oxygen-tolerant on egg or serum media than strains of human origin belonging to the following species.

As pointed out by Lignières and Spitz (Bull. Soc. cent. Méd. vet., *20*, 1902, 487 and 546) and others, distinction should be made between the infections produced by *Actinomyces bovis* and those produced by the Gram-negative *Actinobacillus* now known as *Actinobacillus lignieresi*. These infections frequently occur in mixed form and are also frequently complicated by the presence of pyogenic cocci (Magnussen, Acta path. Microbiol. Scand., *5*, 1928, 170; and others).

Source: Originally found in lumpy jaw of cattle.

Habitat: Frequently found in and about mouth of cattle and probably other animals. Lesions may also be produced in the liver, udder or other organs of cattle and hogs. Possibly also in human mouth (Naeslund, Acta path. Microbiol. Scand., *2*, 1925, 110).

This and the following species are sometimes regarded as being identical (see Emmons, Public Health Repts., U.S.P.H.S., *53*, 1935, 1967; Rosebury, Bact. Rev., *8*, 1944, 190; and others).

2. **Actinomyces israeli** (Kruse) Lachner-Sandoval. (Strahlenpilz, Wolff and Israel, Arch. f. path. Anat., *126*, 1891, 11; *Streptothrix israeli* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 56; *Actinomyces israeli* Lachner-Sandoval, Inaug. Diss., Strassburg, 1898, 64; *Discomyces israeli* Gedoelst, Les champignons parasites de l'homme et des animaux domestiques, 1902, 163; *Actinobacterium israeli* Sampietro, Ann. d'Ig. sperim., *18*, 1908, 331; *Cohnistreptothrix israeli* Pinoy, Bull. Inst. Pasteur, Paris, *11*, 1913, 931; *Nocardia israeli* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 814; *Anaeromyces bronchitica* Castellani, Douglas and Thomson, Jour. Trop. Med. Hyg., *24*, 1921, 149; *Cohnistreptothrix bronchitica* Verdun and Mandoul, Précis Parasitol., 1924, 754; *Brevistreptothrix israeli* Lignières, Annales de Parasit., *2*, 1924, 2; *Proactinomyces israeli* Negroni, Compt. rend. Soc. Biol., Paris, *117*, 1934, 1239; *Corynebacterium israeli* Haupt and Zeki, Cent. f. Bakt., I Abt., Orig., *130*, 1933, 95; *Oospora israeli*, quoted from Nannizzi,

Tratt. Micopat. Umana, *4*, 1934, 53; *Actinomyces wolff-israel* Lentze, Cent. f. Bakt., I Abt., Orig., *141*, 1938, 21.) Named for Prof. Israel, one of the original isolators of this organism.

Synonyms previous to 1919 essentially as given by Breed and Conn, Jour. Bact., *4*, 1919, 597.

Description from Erikson, Med. Res. Council, London, Special Rept. Ser. 240, 1940, 63 pp.

Erect aerial hyphae produced in an atmosphere of reduced oxygen tension. These hyphae are occasionally septate but no definite spores are formed. One micron or more in diameter. Large club-shaped forms are seen in morbid tissues. Gram-positive. Non-motile. Not acid-fast.

Substrate mycelium: Initially unicellular and the branches may extend into the medium in long filaments or may, more or less quickly, exhibit fragmentation and characteristic angular branching. The latter resembles the similar phenomenon found in *Corynebacterium.*

Colonies: These exhibit a considerable degree of polymorphism but no stable variants have been established. Tougher in texture than those of *Actinomyces bovis.* Old colonies warted in appearance. Adherent to the medium.

Gelatin: Occasionally scant, flaky growth. No liquefaction.

Liquid media: Usually clear.

Acid from sugars: According to Slack (Jour. Bact., *43*, 1941, 193–209) acid from glucose, maltose, mannitol, sucrose and lactose; according to Negroni and Bonfiglioli (Physics, *15*, 1939, 159) acid from glucose, galactose, lactose, fructose, maltose, raffinose, sucrose and xylose.

Pigments: No soluble pigments on protein media. No insoluble pigments produced by growth.

Egg or serum media: No proteolytic action.

Litmus milk: Becomes acid but usually does not clot. No peptonization. Frequently no growth.

No hemolysis.

Serology: No cross agglutination between 12 human strains and bovine strains of *Actinomyces.* No cross reactions with representative aerobic strains.

Optimum temperature 37°C.

Anaerobic to microaerophilic.

Source: From 2 cases of human actinomycosis: (1) A retromaxillary tumor, (2) actinomycosis of lung and breast (Wolff and Isreal).

Habitat: From human sources (mouth, tonsillar crypts, etc.). Also reported from various domestic animals such as dogs (Baudet, Ann. Parasit., *12*, 1934, 296) and cats (Edington, Vet. Record., *14*, 1934, 311).

Appendix: The following names have been applied to anaerobic or semi-anaerobic species, with descriptions which do not permit clear separation from the above or from each other.

Actinobacterium meyeri Prévot. (Anaerobe Streptothrix-Art, Meyer, Cent. f. Bakt., I Abt., Orig., *60*, 1911, 75; Prévot, Ann. Inst. Past., *60*, 1938, 303.) From fetid pus.

Actinomyces discofoliatus Grüter. (Grüter, Ztschr. f. Augenheilk., *13*, 1933, 477; redescribed by Negroni, Mycopathologia, *1*, 1938, 81.) From lachrymal concretion and human infection.

Actinomyces lanfranchii Sani. (Sani, 1916, quoted from Dodge, Medical Mycology, St. Louis, 1935, 731; *Nocardia lanfranchii* de Mello and Pais, Arq. Hig. Pat. Exot., *6*, 1918, 178.) From glandular and ganglionar actinomycosis of the ox. Regarded as a variety of *Actinomyces bovis.*

Actinomyces thjoettae Dodge. (*Cohnistreptothrix sp.* or *Streptothrix sp.* Thjøtta and Gundersen, Jour. Bact., *10*, 1925, 1; Dodge, Medical Mycology, 1935, 713.) From the blood in a case of acute rheumatism.

Cohnistreptothrix neschezadimenki (sic) Chalmers and Christopherson. (Eine Streptothrix, Neschezadimenko, Cent. f. Bakt., I Abt., Orig., *46*, 1908, 573; Chalmers and Christopherson, Ann. Trop. Med., *10*, 1916, 273; *Actinomyces neschczadimenki* Dodge, Medical Mycology, 1935, 712; *Actinobacterium abscessus* Prévot, Ann. Inst. Past., *60*, 1938, 303.) From a human infection.

Discomyces carougeaui Gougerot. (Gougerot, Compt. rend. Soc. Biol., Paris, *67*, 1909, 580; *Nocardia carougeaui* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 817; *Cohnistreptothrix carogeanui* (sic) Chalmers and Christopherson, Ann. Trop. Med., *10*, 1916, 273; *Streptothrix carougeaui* Greco, Origine des Tumeurs, 1916, 724; *Actinomyces carougeaui* Brumpt, Précis de Parasitol., 4th ed., 1927, 1206.) From a human infection.

Discomyces thibiergei Ravaut and Pinoy. (Ravaut and Pinoy, Ann. Derm. et Syph., *10*, 1909, 417; *Nocardia thibiergei* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 817; *Cohnistreptothrix thibiergei* Pinoy, Bull. Inst. Past., *11*, 1913, 938; *Oospora thibiergei* Sartory, Champignons Parasites de l'Homme et des Animaux, Fasc. 11, 1923, 792; *Actinomyces thibiergei* Greco, Origine des Tumeurs, 1916, 723.) From a human infection.

Streptothrix cuniculi Schmorl. (Schmorl, Deutsch. Ztschr. f. Thiermed., *17*, 1891, 375; *Actinomyces cuniculi* Gasperini, Ann. Ist. Ig. sper. Univ. Roma, *2*, 1892, 222; *Cladothrix cuniculi* Macé, Traité de Bact., 6th ed., *2*, 1913, 753; *Cohnistreptothrix cuniculi* Chalmers and Christopherson, Ann. Trop. Med., *10*, 1916, 273; *Nocardia cuniculi* Froilani de Mello and Fernandes, Mem. Asiatic Soc. Bengal, 7, 1919, 107; *Oospora cuniculi* Sartory, Champignons parasites de l'Homme et des Animaux, Fasc. 11, 1923, 824.) From infections in rabbits. Generally regarded as probably identical with *Spherophorus necrophorus* (Flügge) Prévot. See page 678.

FAMILY III. STREPTOMYCETACEAE WAKSMAN AND HENRICI.*

(Jour. Bact., *46*, 1943, 339.)

Vegetative mycelium not fragmenting into bacillary or coccoid forms. Conidia borne on sporophores. Primarily soil forms, sometimes thermophilic in rotting manure. A few species are parasitic.

Key to the genera of family **Streptomycetaceae.**

I. Conidia produced in aerial hyphae in chains.

Genus I. *Streptomyces*, p. 929.

II. Conidia produced terminally and singly on short conidiophores.

Genus II. *Micromonospora*, p. 978.

Genus I. **Streptomyces** *Waksman and Henrici.*

(*Streptothrix* Cohn, Beitr. zur Biol. der Pflanzen, *1*, Heft 3, 1875, 186; not *Streptothrix* Corda, Prachtflora Europaescher Schimmelbildung, 1839; *Nocardia* Wright, Jour. Med. Research, *13*, 1905, 349; *Nocardia* Winslow et al., Jour. Bact., *2*, 1917, 554; not *Nocardia* Trevisan, I generi e le specie delle Batteriacee, 1889, 9; *Cohnistreptothrix* (Group I) Ørskov, Investigations in the Morphology of the Ray Fungi. Copenhagen, 1923, 147; not *Cohnistreptothrix* Pinoy, in Liégard and Landrieu, Bull. Soc. Opht., *24*, 1911, 253 and Bull. Inst. Past., *11*, 1913, 929; *Aerothrix* Wollenweber (in part), Ber. deut. Bot. Gesel., *39*, 1921, 26; *Euactinomyces* Langeron (in part), Nouv. Traité de Méd., *4*, 1922; Waksman and Henrici, Jour. Bact., *46*, 1943, 339.)

Organisms growing in the form of a much-branched mycelium with a typical aerial mycelium. Conidiospores formed in chains. Aerobic. Saprophytic soil forms, less commonly parasitic on plants or animals.

This genus can be divided, on the basis of the structure of sporulating hyphae, into five groups:

Group 1. Straight sporulating hyphae, monopodial branching, never producing regular spirals.

Group 2. Spore-bearing hyphae arranged in clusters.

Group 3. Spiral formation in aerial mycelium; long, open spirals.

Group 4. Spiral formation in aerial mycelium; short, compact spirals.

Group 5. Spore-bearing hyphae arranged on mycelium in whorls or tufts.

The type species is *Streptomyces albus* (Rossi Doria *emend.* Krainsky) Waksman and Henrici.

Key to the species of genus **Streptomyces.**

I. Saprophytes; psychrophilic to mesophilic.
   A. Soluble pigment on organic media faint brown, golden-yellow, or blue; pigment may also be absent entirely.
      1. Pigment absent, or faint brown pigment formed at first and later lost; aerial mycelium abundant, white.

         1. *Streptomyces albus.*

      2. Pigment blue or red, when present. The red (insoluble) phase occurs when the reaction is distinctly acid, the blue (soluble) phase when it is alkaline.

         2. *Streptomyces coelicolor.*

---

* Revised by Prof. S. A. Waksman, New Jersey Experiment Station, New Brunswick, New Jersey and Prof. A. T. Henrici, University of Minnesota, Minneapolis, Minnesota, May, 1943.

3. Pigment at first green becoming brown; aerial mycelium usually absent.
   3. *Streptomyces verne.*
4. Pigment yellowish-green; growth on synthetic agar penetrating into medium, pink.
   4. *Streptomyces californicus.*
5. Pigment golden-yellow; growth on synthetic agar yellow, with yellow soluble pigment.
   5. *Streptomyces flaveolus.*
6. Pigment brown (only on certain protein media, as gelatin, glucose broth).
   a. Grown on synthetic agar red to pink. Scant, white aerial mycelium.
      6. *Streptomyces bobiliae.*
   aa. Growth on synthetic agar colorless; aerial mycelium thin, rose-colored.
      7. *Streptomyces roseochromogenus.*
   aaa. Growth on synthetic agar mouse-gray; powdery aerial mycelium.
      8. *Streptomyces griseolus.*
   aaaa. Growth on synthetic agar white turning yellowish, aerial mycelium white.
      9. *Streptomyces erythreus.*

B. Soluble yellow pigment on Ca-malate agar.
1. Proteolytic action strong in milk and gelatin.
   a. Yellow pigment formed.
      b. Cellulose decomposed; starch is hydrolyzed.
         10. *Streptomyces cellulosae.*
      bb. Cellulose not decomposed.
         11. *Streptomyces parvus.*
2. Proteolytic action weak.
   12. *Streptomyces malenconi.*

C. Soluble brown pigment formed on synthetic agar.
1. Yellowish-green pigment on potato.
   13. *Streptomyces diastaticus*
2. Red-brown pigment on potato plug.
   14. *Streptomyces fimicarius.*

D. Greenish-yellow soluble pigment formed; sulfur-yellow pigment on potato.
   15. *Streptomyces flavovirens.*

E. Soluble brown pigment formed in all media containing organic substances.
1. Pigment deep brown (chromogenic type).
   a. Pigment faint brown on organic media, becoming greenish-brown to black; reddish aerial mycelium on glucose agar.
      16. *Streptomyces olivochromogenus.*
   aa. Aerial mycelium yellowish with gray margin; weak diastatic action.
      17. *Streptomyces diastatochromogenes.*
   aaa. Aerial mycelium yellowish; diastatic action weak.
      18. *Streptomyces flavochromogenes.*
   aaaa. Aerial mycelium gray; sporophores in clusters; strongly antibiotic.
      19. *Streptomyces antibioticus.*

2. Growth and aerial mycelium green on synthetic agar.
   20. *Streptomyces viridochromogenes.*
3. Deep brown to black pigment on synthetic agar.
   a. Orange-red on potato; no aerial mycelium on synthetic agar; growing feebly.
      21. *Streptomyces purpeochromogenus.*
   aa. Brown to black on potato; abundant cottony aerial mycelium on synthetic agar.
      b. Brown ring on milk culture; coagulated; peptonized.
         22. *Streptomyces phaeochromogenus.*
      bbb. Black ring on milk; no coagulation; peptonization doubtful.
         23. *Streptomyces aureus.*
         c[1]. Red to rose-red pigment on glucose, maltose, and starch agar.
            24. *Streptomyces erythrochromogenes.*
         c[2]. Lavender-colored aerial mycelium.
            25. *Streptomyces lavendulae.*
         c[3]. Growth on potato gray with black center.
            26. *Streptomyces reticuli.*
         c[4]. Growth on potato cream-colored, becoming pink to dark red.
            27. *Streptomyces rubrireticuli.*
         c[5]. Growth on potato greenish-olive.
            d. Aerial mycelium straw-colored.
               28. *Streptomyces flavus.*
            dd. Aerial mycelium chrome-orange.
               29. *Streptomyces ruber.*

F. No soluble pigment formed on gelatin or other media.
1. Proteolytic action strong in milk and gelatin.
   a[1]. Yellowish-green growth on starch with pinkish aerial mycelium.
      30. *Streptomyces citreus.*
   a[2]. Golden-yellow growth, later becoming orange to red-brown, on synthetic media.
      31. *Streptomyces fulvissimus.*
   a[3]. Cream-colored growth on starch media.
      32. *Streptomyces gougeroti.*
   a[4]. Bluish-black color on synthetic media, with white aerial mycelium.
      33. *Streptomyces violaceoniger.*
   a[5]. Yellowish pigment on potato.
      b. Aerial mycelium thick, powdery, water-green; starch is hydrolyzed.
         34. *Streptomyces griseus.*
      bb. Aerial mycelium white; starch weakly hydrolyzed.
         35. *Streptomyces griseoflavus.*
   a[6]. Greenish-black pigment on potato; aerial mycelium white.
      36. *Streptomyces albidoflavus.*
   a[7]. Reddish-brown pigment on potato; aerial mycelium white; starch is not hydrolyzed.
      37. *Streptomyces poolensis.*

a⁸. Gray to sulfur-yellow pigment on potato.
b. Aerial mycelium mouse-gray to light drab; starch is hydrolyzed.
38. *Streptomyces olivaceus.*
bb. Aerial mycelium yellowish-white.
39. *Streptomyces lieskei.*
bbb. No aerial mycelium; starch is hydrolyzed.
40. *Streptomyces microflavus.*
a⁹. No soluble pigment on potato.
41. *Streptomyces cacaoi.*

2. Proteolytic action weak.
a. Soluble pigment formed on synthetic agar.
b. Pigment blue or blue-black.
42. *Streptomyces novaecaesareae.*
bb. Pigment brown to black.
43. *Streptomyces exfoliatus.*
44. *Streptomyces gelaticus.*
aa. No soluble pigment on synthetic agar.
b¹. Growth turning black; diastatic action strong.
c. Growth on synthetic agar scant with abundant spirals in aerial mycelium.
45. *Streptomyces rutgersensis.*
cc. No spirals on synthetic agar; characteristic green-colored growth on protein-glycerol medium.
46. *Streptomyces lipmanii.*
ccc. No spirals on synthetic agar; growth dark, almost black.
47. *Streptomyces halstedii.*
b². Moist aerial mycelium, many spirals.
48. *Streptomyces hygroscopicus.*
b³. Growth orange-colored.
49. *Streptomyces fradiae.*
b⁴. Growth yellowish.
50. *Streptomyces alboflavus.*
b⁵. Growth rose to red; aerial mycelium white.
51. *Streptomyces albosporeus.*
b⁶. Growth cream-colored; aerial mycelium flaky.
52. *Streptomyces flocculus.*
b⁷. Growth red; aerial mycelium black.
c. Complete decomposition of cellulose; weakly diastatic.
53. *Streptomyces melanosporeus.*
cc. Incomplete decomposition of cellulose; strongly diastatic.
54. *Streptomyces melanocyclus.*

3. No proteolytic action or very little.
a. Acid-resistant strains.
55. *Streptomyces acidophilus.*
aa. Non-acid-resistant.
56. *Streptomyces rubescens.*

II. Saprophytes; thermophilic.
  A. Starch hydrolyzed. Yellowish growth on potato.
    57. *Streptomyces thermophilus.*
  B. Starch not hydrolyzed. Abundant, dark-colored growth on potato.
    58. *Streptomyces thermofuscus.*

III. Plant parasites.
  A. Tyrosinase reaction positive; aerial mycelium gray-white.
    59. *Streptomyces scabies.*
  B. Tyrosinase reaction negative; attacks sweet potatoes.
    60. *Streptomyces ipomoea.*

IV. Isolated from animal tissues. In the animal body, hyphae often show clavate enlargements at the ends.
  A. Limited proteolytic action in gelatin, milk, coagulated egg-albumin or fibrin.
    1. Color of vegetative growth golden-brown.
      61. *Streptomyces fordii.*
    2. Color of vegetative growth pink.
      a. Sparse white aerial mycelium.
        62. *Streptomyces africanus.*
      aa. Formation on mycelium of bodies similar to *Thermoactinomyces.*
        63. *Streptomyces gallicus.*
      aaa. Yellowish-pink growth on potato plug; scant white aerial mycelium.
        64. *Streptomyces pelletieri.*
    3. Color of vegetative growth white.
      65. *Streptomyces listeri.*
    4. Vegetative growth cream-colored, scant white aerial mycelium.
      66. *Streptomyces upcottii.*
    5. Growth very limited on various media, except on potato plug; no liquefaction of gelatin.
      67. *Streptomyces hortonensis.*
  B. Strong proteolytic action in gelatin and milk.
    1. No pigment produced.
      a^1. No growth on potato plug.
        68. *Streptomyces gibsonii.*
      a^2. Moist, membranous growth on potato plug; diastase formed.
        69. *Streptomyces beddardii.*
        70. *Streptomyces kimberi.*
      a^3. Extensive growth on potato media; white powdery aerial mycelium.
      a^4 Abundant growth on potato plug, becoming black; white-gray aerial mycelium; plug discolored.
        71. *Streptomyces somaliensis.*
      a^5. Pink-colored growth on some media.
        72. *Streptomyces panjae.*
      a^6. Profuse white aerial mycelium on most media, spiral formation.
        73. *Streptomyces willmorei.*

1. Streptomyces albus (Rossi Doria *emend.* Krainsky) Waksman and Henrici. (*Streptotrix alba* Rossi Doria, Ann. d'Ist. d'Ig. sper. di. Univ. di Roma, *1*, 1891,

399; *Cladothrix alba* Macé, Traité Pratique Bact., 3rd ed., 1897; *Actinomyces albus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; *Nocardia alba* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 270; Waksman and Henrici, Jour. Bact., *46*, 1943, 339.) From Latin *albus*, white.

Additional synonyms as given by Baldacci (Mycopathologia, *2*, 1940, 156): *Cladothrix dichotoma* Macé, not Cohn, 1886; *Streptothrix foersteri* Gasperini, not Cohn, 1890; *Streptothrix No. 2* and *3*, Almquist, 1890; *Actinomyces saprophyticus* Gasperini, 1892; *Oospora doriae* Sauvageau and Radais, 1892; *Cladothrix liquefaciens* Hesse, 1892 (according to Duché); *Cladothrix invulnerabilis* Acosta and Grande Rossi, 1893; *Actinomyces chromogenus* Gasperini, 1894 (*Streptotrix nigra* Rossi Doria, 1891); *Streptothrix gedanensis I* Scheele and Petruschky, 1897; *Streptothrix gramine-arum* Berestneff, 1898; *Actinomyces thermophilis* (Berestneff) Miehe, not Gilbert, 1898; *Cladothrix odorifera* Rullmann, 1898; *Actinomyces chromogenes* Gasperini *β alba* Lehmann and Neumann, 1899; *Oospora sp.* Bodin, 1899 (according to Duché); *Oospora alpha* Price-Jones, 1900 (according to Chalmers and Christopherson); *Streptothrix leucea* Foulerton, 1902 (according to Chalmers and Christopherson); *Streptothrix candida* Petruschky, 1903; *Streptothrix lathridii* Petruschky, 1903; *Streptothrix dassonvillei* Brocq-Rousseau, 1907 (according to Duché); *Streptothrix pyogenes* Caminiti, 1907 (according to Chalmers and Christopherson); *Streptothrix sanninii* Ciferri, 1922; *Actinomyces almquisti* Duché, 1934; *Actinomyces gougeroti* Duché, 1934. Doubtful synonyms: *Oospora metchnikowi* Sauvageau and Radais, 1892; *Oospora guignardi* Sauvageau and Radais, 1892; *Actinomyces albus* Waksman and Curtis, 1919; *Actinomyces thermodiastaticus* Bergey, (1919) 1925. Varieties: *Actinomyces albus* var. *acidus* Neukirch, 1902 (according to Nannizzi); *Actinomyces albus* var. *ochroleucus* Neukirch, 1902 (according to Wollenweber); *Actinomyces albus* var. *toxica* Rossi, 1905; *Actinomyces albus* var. *cretaceus* (Krüger) Wollenweber, 1920; *Actinomyces albus* var. *α* Ciferri, 1927.

More complete information regarding these species will be found in the text or in the Appendix to Genus *Streptomyces*.

The description of this species by Rossi Doria is incomplete. The characters given below are taken from Krainsky (*loc. cit.*) with some supplementary information from later authors. Other descriptions which may vary from this in certain details are given by Waksman and Curtis (Soil Sci., *1*, 1916, 117), Bergey et al. (Manual, 1st ed., 1923, 367), Duché (Les actinomyces du groupe albus, Paris, 1934, 257) and Baldacci (*loc. cit.*).

Vegetative hyphae: Branched, 1 micron in diameter.

Aerial mycelium: Abundant, white. Hyphae 1.3 to 1.7 microns in diameter with ellipsoidal spores (1 micron long) in coiled chains on lateral branches of the aerial hyphae.

Gelatin: Liquefaction. Colonies gray, no soluble pigment.

Ca-malate agar: Colonies of medium size, the center only is covered with a white aerial mycelium.

Starch agar: Aerial mycelium white but covers the whole surface.

Glucose agar: Gray aerial mycelium becoming brownish.

Peptone and bouillon agar: No aerial mycelium but a chalky white deposit forms on old colonies.

Odor: Earthy or musty.

Broth: Flaky growth on bottom with surface pellicle in old cultures.

Potato: Colonies and aerial mycelium white.

Carrots and other vegetables: Excellent growth (Duché).

No growth on cellulose.

No hydrolysis of starch.

Actively proteolytic.

Nitrites produced from nitrates.

Milk: Peptonized after coagulation. Reaction becomes alkaline (Duché).

Aerobic.

Source: From air and soil (Rossi Doria); from garden soil (Krainsky).

Habitat: Dust, soil, grains and straw. Widely distributed.

2. **Streptomyces coelicolor** (Reiner-Müller) *comb. nov.* (*Streptothrix coelicolor* Reiner-Müller, Cent. f. Bakt., I Abt., Orig., *46*, 1908, 197; *Nocardia coelicolor* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 271; *Actinomyces coelicolor* Lieske, Morphol. u. Biol. d. Strahlenpilze, Leipzig, 1921, 28.) From Latin *caelum*, sky and *color*, color.

Regarded by the authors of this section as the same as *Actinomyces violaceus* Waksman and Curtis, Soil Science, *1*, 1916, 110 (*Actinomyces violaceus-ruber* Waksman and Curtis, *ibid.*, 127; *Actinomyces waksmanii* Bergey et al., Manual, 3rd ed., 1930, 489) and *Actinomyces tricolor* Wollenweber, Arbeiten d. Forschungsinstitut für Kartoffelbau, 1920, 13. It is, however, pointed out by J. E. Conn (Jour. Bact., *46*, 1943, 133) that certain differences between the descriptions of Waksman and Curtis, and that of Müller may correspond to actual chemical differences in the pigments produced; and that the organism of Waksman and Curtis may be a separate species.

Description by Müller except as noted.

Morphology of *Streptomyces coelicolor* has not been fully described. According to Waksman and Curtis who described *Actinomyces violaceus-ruber*, this is as follows: Straight filaments with open, dextrorse spirals, breaking up into conidia. Conidia oval or rod-shaped, 0.7 to 1.0 by 0.8 to 1.5 microns.

Gelatin: Good growth. No pigment formation. Liquefaction fairly rapid, beginning in 4 to 7 days.

Plain agar: Good growth. Pigment lacking or faint blue (Conn).

Czapek agar (according to Waksman and Curtis concerning *Actinomyces violaceus-ruber*): Thin, spreading, colorless at first, becoming red, then blue. Aerial mycelium thin, white, powdery, becoming mouse-gray.

Asparagine agar (synthetic): With glycerol as source of carbon, good growth, violet to deep blue, with pigment diffusing through medium; final H-ion concentration about pH 7.0 to 8.0. With glucose as source of carbon, poorer growth, red, no diffusion of pigment; final H-ion concentration about pH 6.0 to 5.0 (Conn).

Broth: Good growth. Cretaceous layer around edge.

Milk: No change at 25°C (Conn). At 37°C, coagulation. Peptonization beginning in 3 to 5 days.

Potato: Strong pigment production, sometimes greenish-blue or violet, but usually sky-blue, diffusing through medium and coloring water at base of tube.

Nitrites produced from nitrates.

Blood agar: Hemolysis showing on 4th day.

Müller reports no acid from carbohydrates on organic media. Conn, however, finds acid from glucose and lactose, and sometimes from sucrose and mannitol when grown on synthetic media.

Pigment: The most striking characteristic of this organism is a litmus-like pigment usually produced on potato or synthetic media, which is deep blue and water-soluble at alkaline reactions (beyond pH 8.0), violet around neutrality, and red (insoluble in water) at about pH 6.0. Conn points out that the primary pigment has a spectrophotometric curve almost identical with that of azolitmin; but that there are undoubtedly other pigments produced, especially in the case of the strains believed to be typical of *Actinomyces violaceus-ruber* (as previously pointed out by Waksman and Curtis).

Good growth at room temperature and at 37°C.

Aerobic.

Distinctive character: Litmus-like pigment.

Source: Dust contamination on a potato slant.

Habitat: Soil and plant surfaces. Very abundant.

NOTE: Because of the numerous colors and shades shown by the pigment according to final H-ion concentration and other less understood factors, this species may have been described under various names. On the other hand, it is entirely possible, as pointed out by Conn (*loc. cit.*), that careful study of the pigments may show that more than one species is actually involved.

3. **Streptomyces verne** (Waksman and Curtis) *comb. nov.* (*Actinomyces verne* Waksman and Curtis, Soil Science, *1*, 1916, 120.) Derivation uncertain.

Filaments with close branching of the hyphae. No conidia demonstrated.

Gelatin stab: Small, cream-colored colonies. Rapid liquefaction.

Synthetic agar: Abundant, spreading, wrinkled, elevated, glossy, yellowish growth, becoming brownish, lichenoid margin.

Starch agar: Scant, brownish, restricted growth.

Glucose agar: Abundant, much folded growth, center raised, gray with purplish tinge, entire.

Plain agar: Small, grayish colonies with depressed center, becoming wrinkled.

Glucose broth: Slightly flaky sediment.

Litmus milk: Pinkish-brown ring; coagulated; peptonized, with alkaline reaction.

Potato: Cream-colored growth, becoming gray, wrinkled.

Nitrites produced from nitrates.

Soluble brown pigment formed. Soluble green pigment produced when freshly isolated.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Source: Isolated once from upland California soil.

Habitat: Soil.

4. **Streptomyces californicus** (Waksman and Curtis) *comb. nov.* (*Actinomyces californicus* Waksman and Curtis, Soil Science, *1*, 1916, 122.) Named for the State of California.

Filaments with long, narrow, open spirals. Spherical to oval conidia from straight and spiral hyphae.

Gelatin stab: Gray, moist, abundant surface growth. Liquefaction in 30 days.

Synthetic agar: Spreading, vinaceous-colored growth. Aerial mycelium powdery, thin, light neutral gray.

Starch agar: Growth spreading, pink center with colorless to gray margin.

Glucose agar: Restricted, much folded, cream-colored growth, with sulfur-yellow tinge.

Plain agar: Thin, restricted, yellowish to cream-colored growth.

Glucose broth: Solid cream-colored mass on surface, with pink tinge.

Litmus milk: Faint, brownish surface growth; coagulated; peptonized in 40 days.

Potato: Glossy, yellow to red growth, turning red-brown.

Nitrites produced from nitrates.

No soluble pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Source: Isolated once from California sandy loam.

Habitat: Soil.

5. **Streptomyces flaveolus** (Waksman) *comb. nov.* (Actinomyces 168, Waksman, Soil Science, *8*, 1919, 134; *Actinomyces flaveolus* Waksman, in Manual, 1st ed., 1923, 368; *Actinomyces heimi* Duché, Actinomyces du groupe albus. Encyclopédie Mycologique, Paris, *6*, 1934, 359.) From Latin *flavus*, yellow and *eolus*, diminutive ending; hence, somewhat yellow.

Numerous closed and open spirals on all media. Conidia oval to elliptical.

Gelatin stab: Liquefied; abundant, yellowish, spreading pellicle.

Synthetic agar: Growth light sulfur-yellow turning to cadmium-yellow, penetrating deep into medium. Aerial mycelium as white to ash-gray patches.

Starch agar: White, spreading growth.

Glucose agar: Restricted growth, surface folded, raised.

Plain agar: White, glistening, wrinkled growth.

Glucose broth: Thin, yellow pellicle.

Litmus milk: Sulfur-yellow ring; coagulated; peptonized, with faintly alkaline reaction.

Potato: Abundant, wrinkled, cream-colored growth.

Nitrites produced from nitrates.

Soluble empire-yellow pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.

Habitat: Soil.

6. **Streptomyces bobiliae** (Waksman and Curtis) *comb. nov.* (*Actinomyces bobili* Waksman and Curtis, Soil Science, *1*, 1916, 121.) From the name of a person.

Mycelium with branching hyphae. Few close spirals of a dextrorse type.

Gelatin stab: Dense, cream-colored to brownish surface growth. Rapid liquefaction.

Synthetic agar: Abundant, glossy, wrinkled, elevated, coral-red growth becoming deep red. Scant, white aerial mycelium.

Starch agar: Restricted, finely wrinkled, coral-red growth with hyaline margin.

Plain agar: Restricted, glossy, gray growth, becoming brownish.

Glucose broth: Round colonies in fluid. Flaky sediment.

Litmus milk: Dark brown ring. No coagulation. Peptonized.

Potato: Thin, yellowish growth, becoming red, dry and wrinkled.

Nitrites produced from nitrates.

Soluble brown pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Source: Isolated once from adobe and garden soils.

Habitat: Soil.

7. **Streptomyces roseochromogenus** (Jensen) *comb. nov.* (*Actinomyces roseus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; Waksman and Curtis, Soil Science, *1*, 1916, 125; Waksman, Soil Science, *8*, 1919, 148; not *Actinomyces roseus* Namyslowski, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 567; *Nocardia rosea* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 270; *Actinomyces roseochromogenus* Jensen, Proc. Linnean Soc. New So. Wales, *56*, 1931, 359.) From Latin, producing rose color.

Filaments with numerous open and closed spirals. Conidia 1.0 to 1.2 by 1.5 to 3.0 microns.

Gelatin stab: Liquefaction, with small, cream-colored colonies in bottom of liquid.

Synthetic agar: Thin, spreading, colorless growth. Aerial mycelium thin, pale, brownish.

Starch agar: Colorless, spreading growth.

Glucose agar: Growth extensive, spreading, colorless, entire.

Plain agar: White growth, becoming yellowish.

Glucose broth: Cream-colored ring, with flaky sediment.

Litmus milk: Brownish ring. No coagulation. Peptonized in 10 to 15 days, becoming strongly alkaline.

Potato: Much wrinkled, brownish growth.

Nitrites produced from nitrates.

Purple pigment on egg media; brown on gelatin.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.
Habitat: Soil.

8. **Streptomyces griseolus** (Waksman) *comb. nov.* (Actinomyces 96, Waksman, Soil Science, *8*, 1919, 121; *Actinomyces griseolus* Waksman, in Manual, 1st ed., 1923, 369.) From Latin *griseus*, gray and *eolus*, diminutive ending; hence, somewhat gray.

Branching mycelium; no spirals observed. Conidia spherical or oval-shaped.

Gelatin stab: Liquefied with yellowish, flaky pellicle and sediment.

Synthetic agar: Colorless, thin, spreading growth, chiefly in the medium; surface growth limited almost entirely to the aerial mycelium. Aerial mycelium at first gray, later becoming pallid, neutral-gray.

Starch agar: Grayish-brown growth, with dark ring.

Glucose agar: Spreading growth, both on the surface and into the medium; center raised, cream-colored, turning dark.

Plain agar: Brownish growth, with smooth surface.

Glucose broth: Thick, brown ring.

Litmus milk: Abundant growth, pink pellicle; coagulated; peptonized, becoming alkaline.

Potato: Cream-colored growth, becoming black, spreading.

Nitrites produced from nitrates.

Faint brownish soluble pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.

Habitat: Soil.

9. **Streptomyces erythreus** (Waksman) *comb. nov.* (Actinomyces 161, Waksman, Soil Science, *8*, 1919, 112; *Actinomyces erythreus* Waksman, in Manual, 1st ed., 1923, 370; *Actinomyces krainskii* Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 306.) From Greek *erythrus*, red.

Mycelium fine, branching; numerous open spirals formed as side branches of the main hyphae.

Gelatin stab: Abundant, dense, gray growth with pinkish tinge, chiefly on surface of liquefied medium.

Synthetic agar: Spreading growth with irregular margin, developing deep into the medium; color at first white, later turning yellowish, agar around growth has a white, milky surface. Aerial mycelium, thick, solid, white.

Starch agar: Cream-colored, circular colonies, with faint greenish tinge.

Glucose agar: Abundant, spreading, cream-colored growth, later turning brown chiefly on surface; center raised, lobate margin.

Plain agar: Cream-colored growth.

Glucose broth: Abundant, cream-colored surface growth.

Litmus milk: Yellowish surface zone; coagulated; peptonized, becoming alkaline.

Potato: Wrinkled, cream-colored growth, becoming yellowish.

Nitrites produced from nitrates.

Soluble purple pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.

Similar to *Streptomyces erythrochromogenes* (Species No. 24) except that no brown soluble pigment is formed.

Source: From California and Hawaiian soils.

Habitat: Soil.

10. **Streptomyces cellulosae** (Krainsky) *comb. nov.* (*Actinomyces cellulosae* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662.) From M. L. *cellulosa*, cellulose.

Conidia almost spherical, 1.3 microns in diameter, often arranged in chains.

Gelatin colonies: Circular, yellowish.

Gelatin stab: Liquefied.

Plain agar: White aerial mycelium.

Ca-malate agar: Yellowish colonies;

gray aerial mycelium. Soluble yellow pigment formed.

Glucose agar: Abundant growth, gray aerial mycelium. Soluble yellow pigment.

Starch agar: Same as on glucose agar.

Glucose broth: Coarse, flaky growth. Yellow pigment.

Litmus milk: Peptonized.

Potato: Light gray growth; gray aerial mycelium.

Nitrates show slight reduction.

Strong diastatic action. Esculin is hydrolyzed.

Cellulose is decomposed.

Aerobic.

Optimum temperature 30° to 35°C.

Habitat: Soil.

11. **Streptomyces parvus** (Krainsky) *comb. nov.* (*Actinomyces parvus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; *Nocardia parva* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 268.) From Latin *parvus*, small.

Conidia more or less oval, 0.9 to 1.3 by 1.2 to 1.8 microns.

Gelatin: Colonies yellow. Slow liquefaction.

Ca-malate agar: Small, yellow colonies with light yellow aerial mycelium.

Glucose agar: Same as on Ca-malate agar.

Starch agar: Same as on Ca-malate agar.

Glucose broth: Hemispherical colonies in bottom of tube.

Litmus milk: Peptonized.

Nitrate slightly reduced.

Moderate diastatic action.

Cellulose not decomposed.

Aerobic.

Optimum temperature.

Source: Garden soil.

Habitat: Soil.

12. **Streptomyces malenconii** (Duché) *comb. nov.* (*Actinomyces malenconi* Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 353.) Named for Mr. Malençon from whom the original culture was obtained.

Gelatin: Poor growth; liquefaction.

Asparagine glucose agar: Rapid opaque growth, later becoming covered with white aerial mycelium; amber-colored pigment, dissolved in medium.

Peptone agar: Cream-colored lobous growth, covered with whitish aerial mycelium.

Asparagine glucose solution: Long, much branching filaments, 0.5 to 0.7 micron; somewhat heavier aerial mycelium with a few irregular conidia; some flaky growth on bottom of tube; surface growth is cream-colored with rare white aerial mycelium; liquid becomes slightly yellow.

Peptone solution: Whitish growth with yellowish soluble pigment.

Milk: Surface growth with whitish aerial mycelium; slow peptonization, liquid becoming brownish-colored.

Potato: Rapid growth with thin white mycelium; no soluble pigment.

Coagulated serum: Radiating cream-colored growth covered with white aerial mycelium; slow liquefaction.

No pigment on tyrosine medium.

Source: Culture obtained from Mr. Malençon, an inspector in Morocco.

13. **Streptomyces diastaticus** (Krainsky) *comb. nov.* (*Actinomyces diastaticus* Krainsky, Cent. f. Bakt., II Bakt., *41*, 1914, 662; Waksman and Curtis, Soil Science, *1*, 1916, 116.) From M. L. *diastaticus*, diastatic.

Actinomyces roseodiastaticus Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 329 is said to differ from both Krainsky's, and Waksman and Curtis' strains.

Filaments may show fine, long, narrow spirals. Conidia oval, 1.0 to 1.2 by 1.1 to 1.5 microns.

Gelatin stab: Liquefied with small, cream-colored flakes in liquid.

Synthetic agar: Thin, gray, spreading

growth. Aerial mycelium white, becoming drab gray.

Starch agar: Thin, colorless, spreading growth. Aerial mycelium gray.

Glucose agar: Yellowish, spreading growth. No aerial mycelium.

Plain agar: Cream-colored growth. Thin aerial mycelium.

Glucose broth: Gray ring with grayish colonies in bottom of tube.

Litmus milk: Brownish ring; coagulated; peptonized in 25 to 30 days, becoming faintly alkaline.

Potato: Abundant, wrinkled, cream-colored growth with greenish tinge.

Nitrites produced from nitrates.

Brown to dark brown soluble pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Habitat: Soil.

14. **Streptomyces fimicarius** (Duché) *comb. nov.* (*Actinomyces fimicarius* Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 346.) From Latin *fimus*, dung and *carus*, loving.

Gelatin: Punctiform colonies with whitish aerial mycelium; reddish soluble pigment. Liquefaction.

Asparagine agar: Cream-colored growth with whitish aerial mycelium; reverse side, cream-colored to slight ochre.

Czapek's agar: Yellowish masses of growth with yellowish-white aerial mycelium; reverse side orange-colored; faint yellowish soluble pigment.

Peptone agar: Cream-colored growth with white aerial mycelium; reverse side, yellowish.

Asparagine solution: Vegetative filaments 0.5 to 0.6 micron long; branching aerial mycelium 0.8 to 1.0 micron, forming numerous conidia; flaky growth produced on bottom; surface growth becomes covered with a white aerial mycelium; reverse side, brownish-red.

Czapek's solution: Cream-colored punctiform growth with yellowish aerial mycelium; no soluble pigment.

Peptone solution: Whitish growth that flakes throughout liquid; yellowish pigment.

Tyrosine medium: White growth with yellowish reverse; yellowish soluble pigment.

Milk: Colorless growth becoming covered with whitish aerial mycelium; slow peptonization of milk which becomes rose-colored, finally changing to brownish-red.

Potato: Cream-colored to yellowish growth with whitish aerial mycelium; reddish-brown pigmentation of plug.

Coagulated serum: Cream-colored growth with whitish aerial mycelium; rapid liquefaction of serum.

Distinctive characters: Abundant growth upon neutral and acid media; whitish aerial mycelium; marked odor; soluble brownish-red pigment. This species seems to form the transition type between the *Actinomyces albus* group and the *Actinomyces chromogenus* group.

Habitat: Found abundantly in manure.

15. **Streptomyces flavovirens** (Waksman) *comb. nov.* (Actinomyces 128, Waksman, Soil Science, *8*, 1919, 117; *Actinomyces flavovirens* Waksman, in Manual, 1st ed., 1923, 352; *Actinomyces alboviridis* Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 317.) From Latin *flavus*, yellow and *virens*, becoming green.

Large masses of minute tufts; the hyphae coarse, straight, short, relatively unbranched, beaded; open spirals may be produced in certain substances. Conidia spherical, oval to rod-shaped, 0.75 to 1.0 by 1.0 to 1.5 microns.

Gelatin stab: Yellowish-green surface pellicle, consisting of a mass of small colonies, on the liquefied medium.

Synthetic agar: Growth spreading deep into the substratum, yellowish with greenish tinge. Aerial mycelium, gray, powdery.

Starch agar: Greenish-yellow, spreading growth, developing deep into the medium.

Glucose agar: Restricted growth, developing only to a very small extent into the medium, yellow, turning black, edge entire.

Plain agar: Yellowish growth; the reverse dark in center with yellowish zone and outer white zone.

Glucose broth: Thick, sulfur-yellow pellicle or ring.

Litmus milk: Cream-colored to brownish ring; coagulated; peptonized, becoming faintly alkaline.

Potato: Sulfur-yellow, wrinkled growth.

Only a trace of nitrite is formed from nitrates.

Greenish-yellow soluble pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.

Habitat: Soil.

16. **Streptomyces olivochromogenus** (Bergey et al.) *comb. nov.* (*Actinomyces chromogenus 205*, Waksman, Soil Science, 8, 1919, 106; *Actinomyces olivochromogenus* Bergey et al., Manual, 2nd ed., 1925, 368.) From Greek, producing an olive color.

Filaments with numerous close spirals. Conidia oval or elliptical.

Gelatin stab: Cream-colored, spreading surface growth. Rapid liquefaction.

Synthetic agar: White, spreading growth. Aerial mycelium ash gray with brownish tinge.

Starch agar: Transparent, spreading growth.

Glucose agar: Abundant, natal brown to almost black growth, entire margin.

Plain agar: Wrinkled, brown growth, becoming gray-green.

Glucose broth: Thin, brown growth, flaky sediment.

Litmus milk: Dark brown ring; coagulated; peptonized, becoming alkaline.

Potato: Small, wrinkled, black colonies.

Faint traces of nitrites formed from nitrates.

Soluble brown pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Habitat: Soil.

17. **Streptomyces diastatochromogenes** (Krainsky) *comb. nov.* (*Actinomyces diastatochromogenes* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662.) From Greek, probably intended to mean producing both diastase and color.

Conidia spherical or oval, about 1.2 microns.

Gelatin colonies: Light gray-colored.

Gelatin stab: Liquefied.

Plain agar: Medium-sized colonies, with white to gray aerial mycelium.

Ca-malate agar: Medium-sized colonies, colorless, with gray aerial mycelium.

Glucose agar: Same as on Ca-malate agar.

Starch agar: Same as on Ca-malate agar.

Glucose broth: Flaky colonies in depth at first, later also over surface.

Potato: Light gray colonies; gray aerial mycelium; medium colored black.

Soluble brown pigment formed in gelatin.

Weakly diastatic.

No growth on cellulose.

Tyrosinase formed.

Aerobic.

Optimum temperature 35°C.

Habitat: Soil.

18. **Streptomyces flavochromogenes** (Krainsky) *comb. nov.* (*Actinomyces flavochromogenes* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662.) From Latin *flavus*, yellow and Greek, producing color.

Conidia oval, 1.7 microns.

Gelatin colonies: Yellowish colonies.

Gelatin stab: Slight liquefaction.

Plain agar: Aerial mycelium formed late, at first white, later gray. Gray soluble pigment formed.

Ca-malate agar: Colonies yellow with white aerial mycelium forming late.

Glucose agar: Brown soluble pigment formed.

Starch agar: Yellow colonies, with white aerial mycelium.

Glucose broth: Fine flakes, with small spherical colonies adherent to glass. Medium colored brown.

Potato: Yellow colonies, with white aerial mycelium.

Nitrites produced from nitrates.

Weakly diastatic. Esculin acted upon.

Slow growth on cellulose.

Tyrosinase formed.

Aerobic.

Optimum temperature 35°C.

Habitat: Soil.

19. **Streptomyces antibioticus** (Waksman and Woodruff) *comb. nov.* (*Actinomyces antibioticus* Waksman and Woodruff, Jour. Bact., *42*, 1941, 232 and 246.) From Greek, antibiotic.

Spore-bearing hyphae produced in the form of straight aerial hyphae. The conidiophores are arranged in clusters; no spirals formed. The conidia are nearly spherical to somewhat elliptical.

Gelatin: Dark brown growth on surface, with patches of gray aerial mycellium. Dark pigment produced, which gradually diffuses into the unliquefied part of the gelatin. Liquefaction at first very slow, later becoming rapid.

Czapek's agar: Thin, whitish growth. Thin, gray aerial mycelium.

Peptone media: Production of dark pigment at early stage of growth is very characteristic. Growth brownish, thin, with a yellowish-gray to yellowish-green aerial mycelium.

Potato plug: Folded, brown-colored growth, with a thin black ring on plug, fading into a bluish tinge. No aerial mycelium.

Carrot plug: Cream-colored to faint brownish growth. No aerial mycelium. No pigment.

Litmus milk: Thick, brownish ring on surface of milk. Mouse-gray aerial mycelium with greenish tinge; growth becomes brown, especially in drier portions adhering to glass. No reaction change, no coagulation of milk, no clearing; whitish sediment at bottom of tube. Old cultures: Heavy growth ring on surface of milk, heavy precipitation on bottom; liquid brownish to black in upper portion.

Odor: Very characteristic soil odor.

Antagonistic properties: Has a marked antagonistic effect on Gram-positive and Gram-negative bacteria, much more on the former than on the latter, as well as on actinomycetes. It is also active against fungi, which vary in degree of sensitivity. Produces a specific bacteriostatic and bactericidal substance known as actinomycin (Waksman and Woodruff, Jour. Bact., *40*, 1940, 581).

Source: Isolated from soil on *Escherichia coli*-washed-agar plate, using living cells of *E. coli* as the only source of available nutrients.

Habitat: Soil.

20. **Streptomyces viridochromogenes** (Krainsky) *comb. nov.* (*Actinomyces viridochromogenes* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; Waksman and Curtis, Soil Science, *1*, 1916, 114.) From Latin, green and Greek, producing color.

Filaments with numerous open spirals, 3 to 5 microns in diameter, occurring as side branches and terminal conidia, short ovals or spheres, 1.25 to 1.5 microns.

Gelatin stab: Cream-colored surface growth, becoming greenish. Slow liquefaction.

Synthetic agar: Spreading growth, cream-colored with dark center, becoming dark green; reverse yellowish to light cadmium. Aerial mycelium abundant, spreading, white, becoming light green.

Starch agar: Circular, spreading, yellowish colonies.

Glucose agar: Abundant, spreading, wrinkled, gray growth, becoming black.

Plain agar: Abundant, restricted, gray growth, with greenish tinge.

Glucose broth: Dense, solid ring, brownish, becoming dark green.

Litmus milk: Dark brown surface growth; coagulated; peptonized, with faintly alkaline reaction.

Potato: Abundant, gray-brown growth.

Nitrites produced from nitrates.

Soluble brown pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Habitat: Soil.

21. **Streptomyces purpeochromogenus** (Waksman and Curtis) *comb. nov.* (*Actinomyces purpeochromogenus* Waksman and Curtis, Soil Science, *1*, 1916, 113.) From Latin, purple and Greek, producing color.

Branching mycelium and hyphae with few imperfect spirals. Conidia spherical, 0.75 to 1.0 micron in diameter.

Gelatin stab: Slow, brownish surface growth. Slow liquefaction.

Synthetic agar: Slow, restricted, smooth, gray growth, becoming brown with purplish tinge; center raised. Margin yellow.

Starch agar: Small, dark brown colonies.

Glucose agar: Abundant, restricted, gray growth, becoming brown to dark brown.

Plain agar: Gray to brownish growth, becoming dark brown, almost black.

Glucose broth: Slight, flaky sediment.

Litmus milk: Dark-brown ring; coagulated; slowly peptonized, with faintly alkaline reaction.

Potato: Restricted, orange to orange-red growth.

Nitrites not produced from nitrates.

Soluble dark brown pigment formed.

Starch shows slight hydrolysis.

Aerobic.

Optimum temperature 25°C.

Source: Isolated once from California adobe soil.

Habitat: Soil.

22. **Streptomyces phaeochromogenus** (Conn) *comb. nov.* (*Actinomyces pheochromogenus* (sic) Conn, N. Y. State Agr. Exp. Sta. Tech. Bull. No. 60, 1917, 16.) From Greek, producing a brown color.

Branching filaments and hyphae, spirals narrow, open, elongated, sinistrorse.

Gelatin stab: Abundant, spreading, cream-colored surface growth, becoming brown. Slow liquefaction.

Synthetic agar: Colorless growth, becoming brown to almost black. Aerial mycelium abundant, white with brownish shade.

Starch agar: Spreading, brownish growth, becoming brown.

Glucose agar: Restricted, much folded, brown growth.

Plain agar: Thin, cream-colored growth, becoming gray.

Glucose broth: Dense, wrinkled pellicle.

Litmus milk: Dark, almost black ring; coagulated, with slow peptonization, faintly alkaline reaction.

Potato: Brown to almost black growth.

Nitrites produced from nitrates.

Soluble brown pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.

Source: Isolated from soil.

Habitat: Soil.

23. **Streptomyces aureus** (Waksman and Curtis) *comb. nov.* (*Actinomyces aureus* Waksman and Curtis, Soil Science, *1*, 1916, 124; not *Actinomyces aurea* Ford, Textb. of Bact., 1927, 220.) From Latin *aureus*, golden.

Mycelium shows numerous spirals. Conidia spherical to oval, 0.6 to 1.0 by 0.8 to 1.4 microns.

Gelatin stab: Fair, cream-colored surface growth, becoming brown, spreading. Liquefied.

Synthetic agar: Thin, spreading, color-

less growth. Aerial mycelium thin, gray, powdery, becoming cinnamon drab.

Starch agar: Thin, transparent, spreading growth.

Glucose agar: Spreading, light orange growth, raised center, hyaline margin.

Plain agar: Restricted, gray growth.

Glucose broth: Thin, brownish ring; flaky sediment.

Litmus milk: Black ring. No coagulation. Peptonization doubtful.

Potato: Abundant, wrinkled, brown growth, becoming black.

Nitrites produced from nitrates.

Soluble brown pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.

Source: Isolated many times from a variety of soils.

Habitat: Soil.

24. **Streptomyces erythrochromogenes** (Krainsky) *comb. nov.* (*Actinomyces erythrochromogenes* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; Waksman and Curtis, Soil Science, *1*, 1916, 112.) From Greek, producing a red color.

Conidia oval, about 2.0 microns long.

Gelatin colonies: Slow growth.

Gelatin stab: Liquefied. A soluble brown pigment formed.

Plain agar: Brown soluble pigment. White aerial mycelium.

Ca-malate agar: Colonies circular, with grayish-white margined aerial mycelium.

Glucose agar: Red pigment formed.

Starch agar: A soluble rose pigment on old cultures.

Glucose broth: Abundant growth. Floating colonies, later a pellicle is formed. Brown soluble pigment.

Potato: Gray aerial mycelium. Medium colored black.

Nitrates show slight reduction.

Weakly diastatic.

No proteolytic enzyme formed.

No growth in cellulose.

Aerobic.

Optimum temperature 30°C.

Source: Soil and roots of *Alnus* (alder).

Habitat: Soil.

25. **Streptomyces lavendulae** (Waksman and Curtis) *comb. nov.* (*Actinomyces lavendulae* Waksman and Curtis, Soil Science, *1*, 1916, 126.) From M. L., lavender.

Hyphae coarse, branching. Spirals close, 5 to 8 microns in diameter. Conidia oval, 1.0 to 1.2 by 1.6 to 2.0 microns.

Gelatin stab: Creamy to brownish surface growth. Liquefied.

Synthetic agar: Thin, spreading, colorless growth. Aerial mycelium cottony, white, becoming vinous-lavender.

Starch agar: Restricted, glistening, transparent growth.

Plain agar: Gray, wrinkled growth.

Glucose broth: Abundant, flaky sediment.

Litmus milk: Cream-colored ring. No coagulation; peptonized, with strong alkaline reaction.

Potato: Thin, wrinkled, cream-colored to yellowish growth.

Nitrites produced from nitrates.

Soluble brown pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Certain strains of this organism produce antibiotics. One such antibiotic, designated as streptothricin, is active both in vitro and in vivo against various Gram-positive and Gram-negative bacteria, fungi and actinomycetes (Waksman and Woodruff, Proc. Soc. Exp. Biol. Med., *49*, 1942, 207; Waksman, Jour. Bact., *46*, 1943, 299).

Source: Isolated once from orchard soil.

Habitat: Soil.

26. **Streptomyces reticuli** (Waksman and Curtis) *comb. nov.* (*Actinomyces reticuli* Waksman and Curtis, Soil Science, *1*, 1916, 118.) From Latin *reticulum*, a small net.

Mycelium in whorls; spirals formed on

glucose agar are sinistrorse. Conidia spherical, 1.0 to 1.4 microns in diameter.

Gelatin stab: Liquefied with small, brown flakes.

Synthetic agar: Colorless growth, with yellowish tinge, becoming brownish, spreading. Aerial mycelium thin, white, cottony.

Starch agar: Brownish-gray growth.

Glucose agar: Restricted, brownish growth, center raised.

Plain agar: Gray, wrinkled growth, becoming brownish.

Glucose broth: Sediment consisting of large colonies.

Litmus milk: Reaction unchanged; coagulated; peptonized.

Potato: Gray growth, with black center.

Nitrites produced from nitrates.

Dark brown pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.

Source: From upland and adobe soils in California.

Habitat: Soil.

27. **Streptomyces rubrireticuli** *nom. nov.* (*Actinomyces reticulus-ruber* Waksman, Soil Science, *8*, 1919, 146; *Actinomyces reticulus* Bergey et al., Manual, 2nd ed., 1925, 373.) From Latin *ruber*, red and *reticulum*, a small net.

Branching filaments with both primary and secondary whorl formation. Spirals formed on glucose agar. Conidia oval-shaped.

Gelatin stab: Surface growth yellowish-red to dragon-pink. Liquefied.

Synthetic agar: Abundant, spreading growth, usually pink. Aerial mycelium thin, rose to pink.

Starch agar: White growth with red tinge.

Glucose agar: Abundant, spreading, rose-red, entire growth.

Plain agar: Red growth, with yellowish margin, becoming red.

Glucose broth: Thin, flaky sediment.

Litmus milk: Abundant, red pellicle; coagulated; peptonized. Reaction unchanged.

Potato: Cream-colored growth, later pink to dark red.

Nitrites produced from nitrates.

Soluble dark brown pigment formed.

Starch is hydrolyzed.

Aerobic.

Certain strains of this organism produce an antibiotic.

Source: Isolated from New Jersey orchard and California upland soils.

Optimum temperature 37°C.

Habitat: Soil.

28. **Streptomyces flavus** (Krainsky) *comb. nov.* (*Actinomyces flavus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; Waksman and Curtis, Soil Science, *1*, 1916, 118; not *Actinomyces flavus* Sanfelice, Cent. f. Bakt., I Abt., Orig., *36*, 1905, 359.) From Latin *flavus*, yellow.

Coarse filaments with branching hyphae. Conidia formed by budding and breaking up of hyphae into oval forms.

Gelatin stab: Small, yellowish masses on surface of liquefied medium.

Synthetic agar: Circular, yellow or sulfur-yellow colonies. Aerial mycelium straw-yellow.

Starch agar: Spreading, cream-colored growth, with pink tinge.

Glucose agar: Restricted, raised, folded, sulfur-yellow growth, center shading to brown.

Plain agar: Gray, spreading, folded growth.

Glucose broth: Small, white colonies in bottom of tube.

Litmus milk: Coagulated; peptonized, becoming distinctly alkaline.

Potato: Elevated, much wrinkled, greenish-olive growth.

Traces of nitrite formed.

Soluble brown pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.
Habitat: Soil.

29. **Streptomyces ruber** (Krainsky) *comb. nov.* (*Actinomyces ruber* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; Waksman, Soil Science, *8*, 1919, 149; not *Actinomyces ruber* Sanfelice, Cent. f. Bakt., I Abt., Orig., *36*, 1904, 355; *Nocardia krainskii* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 268.) From Latin *ruber*, red.

Straight, branching mycelium, radiating. A few spirals may be formed.

Gelatin stab: Liquefaction, with yellow flakes.

Synthetic agar: Abundant, spreading, red growth. Aerial mycelium abundant, cottony, chrome-orange.

Starch agar: Abundant, spreading, red growth.

Glucose agar: Restricted, abundant, entire, coral-red growth.

Plain agar: Restricted, elevated, wrinkled, olive-green growth.

Glucose broth: Red ring, with spongy colonies on the surface.

Litmus milk: Dark ring with red tinge; coagulated; peptonized, with alkaline reaction.

Potato: Elevated, wrinkled, greenish growth.

Nitrites produced from nitrates.

Soluble brown pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Habitat: Soil.

30. **Streptomyces citreus** (Krainsky) *comb. nov.* (*Actinomyces citreus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; Waksman and Curtis, Soil Science, *1*, 1916, 99; not *Actinomyces citreus* Gasperini, Cent. f. Bakt., *15*, 1894, 684.) From M. L. *citreus*, lemon-yellow.

Filaments with long, narrow open spirals. Conidia spherical to oval, 1.2 to 1.5 by 1.2 to 1.8 microns.

Gelatin stab: Yellowish, restricted surface growth. Liquefaction in 35 days.

Synthetic agar: Abundant, spreading, raised, wrinkled, citron-yellow growth. Aerial mycelium covering surface; citron-yellow.

Starch agar: Abundant, yellowish-green growth.

Glucose agar: Extensive, glossy, olive-yellow, entire growth; center elevated.

Plain agar: Restricted, cream-colored growth.

Glucose broth: Thin, wide, yellow ring; flaky sediment.

Litmus milk: Cream-colored surface growth; coagulated; peptonized, becoming alkaline.

Potato: Yellowish growth, aerial mycelium white.

Trace of nitrite production from nitrate.

The pigment formed is not soluble.

Starch hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Habitat: Soil.

31. **Streptomyces fulvissimus** (Jensen) *comb. nov.* (*Actinomyces fulvissimus* Jensen, Soil Science, *30*, 1930, 66.) From Latin *fulvissimus*, very yellow.

Vegetative mycelium without any special characteristics; aerial mycelium of short, straight, often trifurcated hyphae, 1.0 to 1.2 microns broad; no spiral formation; branches of hyphae break up into conidia, 1.0 to 1.2 by 1.2 to 1.5 microns.

Gelatin: Vegetative mycelium narrow, smooth, yellowish-brown to red-brown; no aerial mycelium; no pigment; gelatin completely liquefied in 10 to 12 days.

Nutrient agar: Good growth; vegetative mycelium raised, finely wrinkled, deep red-brown; no aerial mycelium; brownish-yellow pigment.

Czapek's agar: Good growth (one strain very scant), vegetative mycelium flat, narrow, first light golden, later deep orange to red-brown; aerial mycelium scant, sometimes almost absent, first

white, later light grayish-brown; pigment very characteristic, bright golden to orange.

Glycerol agar: Good growth; vegetative mycelium narrow, raised, smooth, golden to dark bronze; aerial mycelium scant, in patches, white to light cinnamon-brown; pigment intensely golden to orange.

Starch-casein agar: Good growth; vegetative mycelium spreading, folded, yellowish-brown; aerial mycelium abundant, smooth, lead-gray; pigment dull yellow to orange.

Potato: Good growth; vegetative mycelium raised, much wrinkled, rust-brown; aerial mycelium absent or traces of white; pigment gray to faint lemon-yellow.

Loeffler's blood serum: Vegetative mycelium red-brown; no aerial mycelium; yellowish pigment; no liquefaction.

Distinctive characters: The characteristic golden pigment is formed in nearly all media in which the organism grows, but becomes most typical and attains its greatest brightness in synthetic agar media; it has indicator properties, turning red in strongly acid solutions. The species is easily recognized on agar plates by its bronze-colored colonies, surrounded by haloes of bright yellow pigment.

Source: Very common in Danish soils.

Habitat: Soil.

32. **Streptomyces gougeroti** (Duché) *comb. nov.* (*Actinomyces gougeroti* Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 272.) Named for Prof. Gougerot, from whom the culture was obtained.

Gelatin: Cream-colored colonies developing slowly with faint aerial mycelium; no pigment; liquefaction.

Plain agar: Cream-colored growth forming concentric ring with age, with brownish reverse; faint yellowish soluble pigment.

Synthetic agar: Slow growth as punctiform colonies; cream-colored with smooth edge; no aerial mycelium; no soluble pigment.

Peptone broth: Cream-colored ring on surface of medium with flakes throughout the medium; no soluble pigment.

Synthetic solution: Submerged mycelium in the form of flakes, later forming a surface pellicle; filaments of aerial mycelium 1 micron in diameter, with numerous conidia; cream-colored growth; no soluble pigment.

Tyrosine medium: Good growth with white aerial mycelium; no soluble pigment.

Litmus milk: Growth in the form of colonies which remain separated from one another; also flakes in the bottom of the tube with bluish tinge on reverse of growth; milk turns blue in 10 to 12 days.

Coagulated serum: Cream-colored growth covered with white aerial mycelium; rapid liquefaction of serum.

Potato: Slow growth of a greenish tinge; aerial mycelium; no black pigment.

Distinctive character: Intermediate between *Streptomyces albus* with its abundant aerial mycelium and *Actinomyces almquisti* with its very scanty aerial mycelium.

Source: Culture obtained from the collection of Prof. Gougerot.

33. **Streptomyces violaceoniger** (Waksman and Curtis) *comb. nov.* (*Actinomyces violaceus-niger* Waksman and Curtis, Soil Science, *1*, 1916, 111.) From Latin *violaceus*, violet and *niger*, black.

Gelatin: Gray growth, with no production of aerial mycelium. Gelatin around colony rapidly liquefied, but without any change in color.

Czapek's agar: Colony at first dark gray, turning almost black, 2 to 4 mm in diameter. Surface glossy, much folded with a very thin gray margin. A white to gray aerial mycelium is produced after the colony has well developed. A bluish-black pigment is produced at a later stage of its growth. The pigment slowly dissolves in the medium, turning almost

black. Odor fairly strong. Microscopically two types of mycelium are found: the thin, branching filaments of the substratum, and the thick filaments of the aerial mycelium. The aerial mycelium fragments not very rapidly, producing a few conidia, spherical and oval, 1.2 to 1.5 by 1.2 to 2.3 microns. These often occur in chains.

Czapek's solution: Colonies large, 2 to 3 mm in diameter, appearing at the bottom and surface of the solution, but none throughout the medium. Colonies bluish in color, with a regular margin. Medium not colored.

Potato plug: Growth at first very slight, but after 48 hours develops into a yellowish-gray continuous thick smear which later turns brown, with a white aerial mycelium covering the growth. Medium not colored.

Source: Isolated once from the upland California soil.

Habitat: Soil.

34. **Streptomyces griseus** (Krainsky) *comb. nov.* (*Actinomyces griseus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662.) From M. L. *griseus*, gray.

Branching filaments; a few spirals have been observed. Conidia rod-shaped to short cylindrical, 0.8 by 0.8 to 1.7 microns. Aerial mycelium greenish-gray.

Gelatin stab: Greenish-yellow or cream-colored surface growth with brownish tinge. Rapid liquefaction.

Synthetic agar: Thin, colorless, spreading growth, becoming olive buff. Aerial mycelium thick, powdery, water-green.

Starch agar: Thin, spreading, transparent growth.

Glucose agar: Growth elevated in center, radiate, cream-colored to orange, erose margin.

Plain agar: Abundant, cream-colored, almost transparent growth.

Glucose broth: Abundant, yellowish pellicle with greenish tinge, much folded.

Litmus milk: Cream-colored ring; coagulated with rapid peptonization, becoming alkaline.

Potato: Yellowish, wrinkled growth.

Nitrites produced from nitrates.

The pigment formed is not soluble.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Different strains of this organism produce different antibiotics. One of these, streptomycin, was isolated in crystalline form. It is active against a large number of bacteria and actinomycetes, but not against fungi and viruses. It is not very toxic to animals, and has found extensive application in the treatment of various diseases, mostly caused by Gram-negative bacteria and certain forms of tuberculosis.

Source: Garden soil.

Habitat: Soil.

35. **Streptomyces griseoflavus** (Krainsky) *comb. nov.* (*Actinomyces griseoflavus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662.) From M. L. *griseus*, gray and Latin *flavus*, yellow.

Conidia oval, 1.2 microns.

Gelatin colonies: Yellowish. Concentric rings.

Gelatin stab: Rapidly liquefied.

Plain agar: Colonies yellowish, with white aerial mycelium.

Ca-malate agar: Large colonies covered with yellow to greenish-gray aerial mycelium.

Glucose agar: White aerial mycelium is slowly formed.

Starch agar: White aerial mycelium.

Glucose broth: Flaky growth.

Litmus milk: Peptonized.

Potato: Yellowish growth, aerial mycelium gray.

Nitrites produced from nitrates.

Weakly diastatic. Acts on esculin.

Grows well on cellulose.

Aerobic.

Optimum temperature 35°C.

Habitat: Soil.

36. **Streptomyces albidoflavus** (Rossi Doria) *comb. nov.* (*Streptotrix* (sic) *albido-flava* Rossi Doria, Ann. d. Ist. d'Ig. sper. d. Univ. di Roma, *1*, 1891, 407; *Actinomyces albido-flavus* Gasperini, *ibid.*, *2*, 1892, 222; *Streptothrix albido* Chester, Man. Determ. Bact., 1901, 365; *Cladothrix albido-flava* Macé, Traité Pratique de Bact., 4th ed., 1901, 1097; *Nocardia albida* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 271.) From Latin *albidus*, white and *flavus*, yellow.

Description from Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 294.

Gelatin: Punctiform colonies with white aerial mycelium on surface of liquid; no soluble pigment; rapid liquefaction.

Synthetic asparagine agar: Growth becomes rapidly covered with white aerial mycelium, later becoming whitish-yellow; brown on reverse side; yellowish soluble pigment.

Peptone agar: Cream-colored growth covered with fine white aerial mycelium; yellow soluble pigment.

Tyrosine agar: Fine growth with orange-yellow on reverse side; medium becomes colored yellowish to yellowish-rose.

Synthetic asparagine solution: Long branching filaments, 0.6 micron in diameter. Thicker aerial mycelium producing irregular spores; flaky growth dropping to bottom of tube. Surface growth becomes covered with yellowish-white aerial mycelium; brownish on reverse side; soluble pigment yellowish.

Peptone solution: Rapid, much folded growth, partly covered with white mycelium on surface of medium; soluble yellow-ochre pigment.

Milk: Rapid growth becoming covered with whitish aerial mycelium; never fully covering the surface; no coagulation; peptonization begins slowly and is completed in 13 days, liquid becoming colored yellowish-orange.

Coagulated serum: Cream-colored growth of surface becoming covered with white aerial mycelium; rapid liquefaction of serum.

Starch medium: Cream-colored growth rapidly colored with yellow aerial mycelium; after 20 days growth becomes much folded; greenish on reverse side; slightly amber color in medium.

This strain is closely related to *Streptomyces albus*. Develops poorly on Czapek's medium without asparagine.

Source: From dust.

37. **Streptomyces poolensis** (Taubenhaus) *comb. nov.* (*Actinomyces poolensis* Taubenhaus, Jour. Agr. Res., *13*, 1918, 446.) Named for Prof. R. F. Poole, plant pathologist.

Description from Waksman, Soil Sci., *8*, 1919, 140.

Fine, branching mycelium; spirals usually not seen. Conidia oval to elliptical.

Gelatin stab: Liquefied, with small, brownish flakes in fluid.

Synthetic agar: Thin, colorless, spreading growth. Aerial mycelium white to gray.

Starch agar: Restricted, cream-colored growth.

Glucose agar: Growth abundant, light brown, glossy, raised center, entire.

Plain agar: Yellowish, translucent growth.

Glucose broth: Thin, brownish ring.

Litmus milk: Brownish ring; coagulated; peptonized, with strongly alkaline reaction.

Potato: Thin, reddish-brown; medium becoming purplish.

Nitrites produced from nitrates.

Faint trace of soluble brown pigment.

Starch not hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Source: Associated with disease of sweet potato.

38. **Streptomyces olivaceus** (Waksman) *comb. nov.* (Actinomyces 206, Waksman, Soil Science, 7, 1919, 117; *Actinomyces olivaceus* Waksman, in Manual, 1st ed., 1923, 354.) From Latin, olive-colored.

Small clumps, with straight and branching hyphae. No spirals on most media. Conidia spherical and oval, 0.9 to 1.1 by 0.9 to 2.0 microns.

Gelatin stab: Liquefied with cream-colored, flaky, yellow sediment.

Synthetic agar: Growth abundant, spreading, developing deep into medium, yellow to olive-ochre, reverse yellow to almost black. Aerial mycelium mouse-gray to light drab.

Starch agar: Thin, yellowish-green, spreading growth.

Glucose agar: Growth abundant, restricted, entire, center raised.

Plain agar: White, glistening growth.

Glucose broth: Sulfur-yellow ring.

Litmus milk: Faint, pinkish growth; coagulated; peptonized, becoming alkaline.

Potato: Growth abundant, much wrinkled, elevated, gray, turning sulfur-yellow on edge.

Nitrites produced from nitrates.

The pigment formed is not soluble.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.

Habitat: Soil.

39. **Streptomyces lieskei** (Duché) *comb. nov.* (*Actinomyces lieskei* Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 289.) Named for Prof. Lieske of Leipzig.

Gelatin: Cream-colored growth becoming covered with white aerial mycelium; no soluble pigment. Rapid liquefaction.

Plain agar: Cream-colored growth becoming covered with white aerial mycelium; yellowish soluble pigment.

Synthetic agar: Cream-colored growth with delayed white aerial mycelium growing from the edge toward the center; mycelium later yellowish. Reverse of growth yellowish to green. Dirty yellow to yellow-green soluble pigment.

Synthetic solution: Long branching filaments 0.7 micron in diameter. Yellowish-white aerial mycelium does not readily produce spores; flakes drop to the bottom of the tube.

Peptone solution: Cream-colored colonies on surface with flakes in the liquid dropping to the bottom of the tube. Liquid becomes yellowish in color.

Tyrosine medium: Rapid growth on surface with whitish-yellow aerial mycelium; yellowish to orange-yellow soluble pigment.

Milk: Cream-colored growth; colorless on reverse side; no aerial mycelium. Peptonization without coagulation. After 20 days the whole milk becomes a clear yellowish liquid.

Coagulated serum: Clear-colored growth. Rapid liquefaction.

Culture related to *Streptomyces alboflavus* and *Streptomyces albidoflavus*.

40. **Streptomyces microflavus** (Krainsky) *comb. nov.* (*Actinomyces microflavus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; *Micromonospora microflava* Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 29.) From Greek *micrus*, small, and Latin *flavus*, yellow.

Conidia large, spherical to rod-shaped, often in pairs or chains, 2.0 by 2.0 to 5.0 microns.

Gelatin colonies: Small, yellow.

Gelatin stab: Liquefied.

Plain agar: Yellow colonies, with rose-yellow aerial mycelium in 3 to 4 weeks.

Ca-malate agar: Minute yellow colonies. No aerial mycelium.

Glucose agar: A rose-yellow aerial mycelium develops in about 12 days.

Starch agar: Same as on glucose agar.

Glucose broth: Small spherical colonies in depth.

Litmus milk: Peptonized.

Potato: Yellow growth. No aerial mycelium.

Nitrites produced from nitrates.

Strongly diastatic.
Scant growth on cellulose.
Starch is hydrolyzed.
Aerobic.
Optimum temperature 25°C.
Habitat: Soil.

41. **Streptomyces cacaoi** (Waksman) *comb. nov.* (*Actinomyces cacaoi* Waksman, in Bunting, Ann. Appl. Biol., *19*, 1932, 515.) Named for the chocolate tree (*Theobroma cacao*).

Long aerial mycelium with considerable spiral formation; the spirals are long and open, not compact.

Gelatin: Flocculent growth. No aerial mycelium. Rapid liquefaction. No pigment production.

Nutrient agar: Brown-colored growth covered with tiny patches of ivory-colored aerial mycelium.

Glucose agar: Thin yellowish growth, later turning reddish-brown; no soluble pigment; light gray to mouse-gray mycelium, with white edge. Typical odor of streptomyces.

Czapek's agar: Same as on glucose agar.

Potato: Abundant brownish growth with white to mouse-gray aerial mycelium.

Biochemical characteristics: Strong proteolytic enzymes acting on casein and gelatin; strong diastatic action, no sugar or dextrin left in 1 per cent starch solution after a few days. Limited reduction of nitrate.

Source: Three strains isolated from cacao beans in Nigeria. There were slight differences among the three strains; the above description is of Strain I.

42. **Streptomyces novaecaesareae** *nom. nov.* (*Actinomyces violaceus-caesari* Waksman and Curtis, Soil Science, *1*, 1916, 111.) From *Nova Caesarea*, Latin name for the State of New Jersey.

Filaments with both straight and spiral aerial hyphae; spirals dextrorse. Conidia oval to elongate.

Gelatin stab: Small, cream-colored surface colonies with slow liquefaction.

Synthetic agar: Growth gray, becoming bluish, glossy, much wrinkled. Aerial mycelium appears late; white.

Starch agar: Restricted, circular, blueish-violet colonies.

Glucose agar: Restricted, gray growth, becoming red.

Plain agar: Thin, cream-colored growth.

Glucose broth: Fine, colorless, flaky sediment.

Litmus milk: Gray ring; coagulated; slow peptonization, becoming faintly alkaline.

Potato: Growth cream-colored, wrinkled, turning yellowish.

Nitrites produced from nitrates.
Soluble purple pigment formed.
Starch is hydrolyzed.
Aerobic.
Optimum temperature 37°C.

Source: Isolated once from upland California soil.

Habitat: Soil.

43. **Streptomyces exfoliatus** (Waksman and Curtis) *comb. nov.* (*Actinomyces exfoliatus* Waksman and Curtis, Soil Science, *1*, 1916, 116.) From Latin, stripped of foliage.

Slightly wavy filaments with tendency to form spirals. Conidia oval, 1.0 to 1.5 by 1.2 to 1.8 microns.

Gelatin stab: Cream-colored surface growth. Liquefied.

Synthetic agar: Growth colorless, becoming brown, smooth, glossy. Aerial mycelium in white patches over surface.

Starch agar: Restricted, gray growth, becoming brown.

Plain agar: Grows only in depth of medium.

Glucose broth: Small, grayish colonies in depth.

Litmus milk: Cream-colored ring, soft coagulum in 12 days; slow peptonization, becoming strongly alkaline.

Potato: Growth somewhat wrinkled, gray, becoming brown.

Nitrites produced from nitrates.
Brown, soluble pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Source: Isolated several times from adobe and upland soils in California.

Habitat: Soil.

44. **Streptomyces gelaticus** (Waksman) *comb. nov.* (Actinomyces 104, Waksman, Soil Science, *8*, 1919, 165; *Actinomyces gelaticus* Waksman, in Manual, 1st ed., 1923, 356.) From M. L. *gelaticus*, gelatinous.

Branching mycelium with open spirals.

Gelatin stab: Liquefied with cream-colored flaky sediment.

Synthetic agar: Growth colorless, spreading, chiefly deep into the medium. Aerial mycelium thin, white, turning grayish.

Starch agar: Thin, spreading, cream-colored growth.

Glucose agar: Abundant, spreading, white growth.

Plain agar: Wrinkled, cream-colored growth only on the surface.

Glucose broth: Thin, cream-colored pellicle; slight flaky sediment.

Litmus milk: Pinkish ring; coagulated; peptonized with distinctly alkaline reaction.

Potato: Growth abundant, much wrinkled, greenish, becoming black with yellowish margin.

Nitrates show slight reduction to nitrites.

Soluble brown pigment formed.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.

Habitat: Soil.

45. **Streptomyces rutgersensis** (Waksman and Curtis) *comb. nov.* (*Actinomyces rutgersensis* Waksman and Curtis, Soil Science, *1*, 1916, 123.) Named for Rutgers University, New Brunswick, New Jersey.

Branching filaments with abundant open and closed spirals; hyphae fine, long, branching. Conidia spherical and oval, 1.0 to 1.2 microns, with tendency to bipolar staining.

Gelatin stab: Cream-colored, spreading surface growth. Liquefied.

Synthetic agar: Growth thin, colorless, spreading, becoming brownish to almost black. Aerial mycelium thin, white, becoming dull-gray.

Starch agar: Gray, spreading growth.

Glucose agar: Abundant, brown mycelium, becoming black with cream-colored margin.

Plain agar: Thin, wrinkled, cream-colored growth.

Litmus milk: Cream-colored ring; coagulated; slow peptonization, becoming alkaline.

Potato: Abundant, white-gray, much folded growth.

Nitrites produced from nitrates.

The pigment formed is not soluble.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Source: Isolated many times from a variety of soils.

Habitat: Common in soil.

46. **Streptomyces lipmanii** (Waksman and Curtis) *comb. nov.* (*Actinomyces lipmanii* Waksman and Curtis, Soil Science, *1*, 1916, 123.) Named for Prof. J. G. Lipman, New Jersey Agricultural Experiment Station.

Straight, branching mycelium and hyphae. Conidia oval, 0.8 to 1.1 by 1.0 to 1.5 microns.

Gelatin stab: Liquefied with cream-colored, flaky sediment.

Synthetic agar: Growth abundant, raised, colorless, becoming light brown and wrinkled. Aerial mycelium white, turning gray.

Starch agar: Transparent growth, becoming dark with age.

Glucose agar: Light yellow, irregular, spreading growth.

Plain agar: Yellow, glossy, radiately wrinkled growth.

Glucose broth: White ring, with abundant, colorless flaky sediment.

Litmus milk: Cream-colored ring; coagulated; peptonization with alkaline reaction.

Potato: Abundant, cream-colored, wrinkled growth.

Nitrites produced from nitrates.

The pigment formed is not soluble.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.

Source: Isolated many times from a variety of soils.

Habitat: Common in soil.

47. **Streptomyces halstedii** (Waksman and Curtis) *comb. nov.* (*Actinomyces halstedii* Waksman and Curtis, Soil Science, *1*, 1916, 124.) Named for a person.

Branching mycelium and hyphae with close spirals. Conidia oval or rod-shaped, 1.0 to 1.2 by 1.2 to 1.8 microns.

Gelatin stab: Liquefied, with small, cream-colored masses in bottom of tube.

Synthetic agar: Growth abundant, heavy, spreading, raised, light, becoming dark, almost black. Aerial mycelium white, turning dull-gray.

Starch agar: Abundant, brownish, glossy growth.

Glucose agar: Growth spreading, colorless, wrinkled, center elevated, edge lichenoid, becoming brown.

Plain agar: Restricted, wrinkled, cream-colored growth.

Glucose broth: Small, colorless colonies in bottom of tube.

Litmus milk: Cream-colored ring; coagulated; peptonized, becoming alkaline.

Potato: Growth abundant, moist, wrinkled, cream-colored with green tinge.

Nitrites produced from nitrates.

The pigment formed is not soluble.

Starch is hydrolyzed.

Optimum temperature 37°C.

Aerobic.

Source: Isolated many times from the deeper soil layers.

Habitat: Common in subsoil.

48. **Streptomyces hygroscopicus** (Jensen) *comb. nov.* (*Actinomyces hygroscopicus* Jensen, Proc. Linn. Soc. New So. Wales, *56*, 1931, 257.) From Greek, hygroscopic.

Hyphae of vegetative mycelium 0.6 to 0.8 micron in diameter. Aerial hyphae long, tangled, branched, 0.8 to 1.0 micron in diameter; spirals numerous, sinistrorse, narrow, usually short, only 1 or 2 turns, closed, typically situated as dense clusters on the main stems of the aerial hyphae. Conidia oval, 0.8 to 1.0 by 1.0 to 1.2 microns.

Gelatin: Slow liquefaction. No pigment produced.

Nutrient agar: Good growth. Vegetative mycelium raised, wrinkled, glossy, cream-colored; later yellowish-gray with yellowish-brown reverse. Occasionally a scant white aerial mycelium.

Sucrose agar: Good to abundant growth. Vegetative mycelium heavy, superficially spreading, folded, glossy surface, white to cream-colored, later sulfur-yellow to yellowish-gray, with golden to light orange reverse. Soluble pigment of the same color. Aerial mycelium scant, thin, white or absent.

Glucose agar: Good growth. Vegetative mycelium superficially spreading, surface granulated, cream-colored to straw-yellow, later dull chrome-yellow to brownish-orange. Aerial mycelium thin, smooth, dusty, white to pale yellowish-gray, after 1 or 2 weeks more or less abundantly interspersed with small, moist, dark violet-gray to brownish patches which gradually spread over the whole surface. Light yellow soluble pigment.

Potato: Fair growth. Vegetative mycelium raised, wrinkled, cream-colored, later yellowish-gray to dull brownish. Aerial mycelium absent or trace of white.

Milk: Completely digested in 3 to 4 weeks at 30°C without any previous coagulation. The reaction becomes faintly acid (pH 6.0 or less).

Nitrates not reduced with sucrose as source of energy.

Sucrose is inverted.

Starch is hydrolyzed.

Cellulose is decomposed readily by some strains.

Distinctive character: In this species, the aerial mycelium (which in other actinomycetes is strikingly hydrophobic) on certain media (glucose or glycerol asparagine agar) becomes moistened and exhibits dark, glistening patches. These patches, when touched with a needle, prove to be a moist, smeary mass of spores. This characteristic feature is not equally distinct in all strains.

Source: Seven strains isolated from soils.

Habitat: Soil.

49. **Streptomyces fradiae** (Waksman and Curtis) *comb. nov.* (*Actinomyces fradii* Waksman and Curtis, Soil Science, *1*, 1916, 125.) From the name of a person.

Straight, branching filaments and hyphae. No spirals. Conidia rod- or oval-shaped, 0.5 by 0.7 to 1.25 microns.

Gelatin stab: Cream-colored to brownish, dense growth on liquid medium.

Synthetic agar: Smooth, spreading, colorless growth. Aerial mycelium thick, cottony mass covering surface, sea-shell pink.

Starch agar: Spreading, colorless growth.

Glucose agar: Growth restricted, glossy, buff-colored, lichenoid margin.

Plain agar: Growth yellowish, becoming orange-yellow, restricted.

Glucose broth: Dense, narrow, orange-colored ring; abundant, flaky, colorless sediment.

Litmus milk: Faint, cream-colored ring; coagulated; peptonized, becoming alkaline.

Potato: Restricted, orange-colored growth.

Nitrites not produced from nitrates.

The pigment formed is not soluble.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 25°C.

Source: Isolated once from adobe soil in California.

Habitat: Soil.

50. **Streptomyces alboflavus** (Waksman and Curtis) *comb. nov.* (*Actinomyces alboflavus* Waksman and Curtis, Soil Science, *1*, 1916, 120.) From Latin *albus*, white and *flavus*, yellow.

Straight, branching mycelium, with very little tendency to form spirals. Very few oval-shaped conidia formed.

Gelatin stab: Abundant, colorless surface growth. Liquefaction occurs in 35 days.

Synthetic agar: Growth glossy, colorless, spreading, becoming yellowish. Aerial mycelium white, powdery, with yellow tinge.

Starch agar: Thin, yellowish, spreading growth.

Glucose agar: Growth restricted, much-folded, creamy with sulfur-yellow surface.

Plain agar: Restricted, cream-colored growth.

Glucose broth: White, cylindrical colonies on surface, later flaky mass in bottom of tube.

Litmus milk: Pinkish ring. No coagulation. Peptonized, becoming alkaline.

Potato: Moist, cream-colored, wrinkled growth.

Nitrites produced from nitrates.

The pigment formed is not soluble.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Source: Isolated once from orchard soil.

Habitat: Soil.

51. **Streptomyces albosporeus** (Krainsky) *comb. nov.* (*Actinomyces albosporeus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 649; *Nocardia albosporea* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 268; Waksman and Curtis, Soil Science, *1*, 1916, 99.) From Latin *albus*, white and Greek *spora*, spore.

Straight, branching filaments with straight, branching hyphae, and occasional spirals. Conidia spherical or oval, 0.8 to 1.2 by 1.0 to 1.8 microns.

Gelatin stab: Growth yellow, changing to red, with hyaline margin. Liquefaction in 35 days.

Synthetic agar: Growth spreading, colorless with pink center, becoming brownish. Aerial mycelium white at first, later covering the surface.

Starch agar: Growth thin, spreading, transparent, with red tinge.

Glucose agar: Growth spreading, red, wrinkled, radiate, entire.

Plain agar: Minute, cream-colored colonies.

Glucose broth: Pinkish ring.

Litmus milk: Scant, pink ring. No coagulation. No peptonization.

Potato: Growth thin, spreading, wrinkled, gray, becoming brown with greenish tinge.

Nitrites produced from nitrates.

The pigment formed is not soluble.

Starch is hydrolyzed.

Aerobic.

Optimum temperature 37°C.

Habitat: Soil.

52. **Streptomyces flocculus** (Duché) *comb. nov.* (*Actinomyces flocculus* Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 300.) From Latin, somewhat woolly, referring to the appearance of the aerial mycelium.

Gelatin: Very limited growth. Slow liquefaction.

Asparagine glucose agar: Weak growth; limited cream-colored colonies hardly raised above the surface of the medium; occasionally abundant growth is produced with white aerial mycelium and colorless on reverse side.

Czapek's agar: Cream-colored growth, later covered with white aerial mycelium; no soluble pigment.

Peptone agar: Cream-colored growth, later covered with white aerial mycelium; no soluble pigment.

Asparagine glucose solution: Branching immersed filaments, 0.8 micron in diameter; aerial mycelium 1.0 by 1.2 microns with numerous conidia; flakes settle to the bottom of the tube.

Peptone solution: Pointed colonies; cream-colored on surface of medium.

Tyrosine medium: Whitish growth without any pigment.

Milk: Rose-colored growth; slow peptonization.

Potato: Punctiform growth covered with white aerial mycelium; faint yellowish pigment.

Coagulated serum: Cream-colored growth; fine white aerial mycelium; slow liquefaction of serum.

Source: Culture obtained from Mr. Malençon, an inspector in Morocco.

53. **Streptomyces melanosporeus** (Krainsky) *comb. nov.* (*Actinomyces melanosporeus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; *Nocardia melanosporea* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 268.) From Greek *melas*, black and *spora*, spore.

Conidia almost spherical, 1.2 microns in diameter.

Gelatin colony: Small, reddish colonies.

Gelatin stab: Liquefied.

Ca-malate agar: Colonies red, with black aerial mycelium.

Glucose agar: Same as on Ca-malate agar.

Starch agar: Same as on Ca-malate agar.

Glucose broth: Flaky, orange-red colonies adherent to glass.

Litmus milk: Peptonized.

Potato: Red colonies with black aerial mycelium.

Nitrites produced from nitrates.

Weakly diastatic.

Grows well on cellulose. Cellulose is decomposed.

Aerobic.

Optimum temperature 25°C.
Habitat: Soil.

54. **Streptomyces melanocyclus** (Merker) *comb. nov.* (*Micrococcus melanocyclus* Merker, Cent. f. Bakt., II Abt., *31*, 1911, 589; *Actinomyces melanocyclus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; *Nocardia melanocycla* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 268.) From Greek *melas*, black and *cyclus*, circle.

Conidia almost spherical, 0.9 micron in diameter.

Gelatin colonies: Growth poor.

Gelatin stab: Rapid liquefaction.

Ca-malate agar: Colonies small, flat, orange-red. Aerial mycelium black, occurring along the edges.

Glucose broth: Same as on Ca-malate agar.

Starch agar: Same as on Ca-malate agar.

Glucose broth: Colorless, spherical colonies.

Litmus milk: Peptonized.

Nitrites produced from nitrates.

Good diastatic action.

Cellulose is decomposed.

Aerobic.

Optimum temperature 25°C.

Habitat: Soil.

55. **Streptomyces acidophilus** (Jensen) *comb. nov.* (*Actinomyces acidophilus* Jensen, Soil Sci., *25*, 1928, 226.) From Greek, acid-loving.

Vegetative mycelium profusely branched, hyphae 0.6 to 0.8 micron in diameter with homogeneous protoplasm and no visible septa. Aerial mycelium with hyphae 1.0 to 1.2 microns in diameter, somewhat branched, forming either very few or very numerous sinistrorse spirals. Oval conidia 1.0 to 1.2 by 1.2 to 1.5 microns.

Gelatin: After 10 days growth very scant, thin, colorless, semi-transparent. Slow liquefaction.

Nutrient agar: No growth.

Glucose agar: Good growth at 25°C. Substratum mycelium raised, somewhat wrinkled, colorless in young cultures. Aerial mycelium thin, white at first, later gray or yellowish-brown.

Starch agar: Good growth at 25°C. Substratum mycelium flat, smooth, colorless. Aerial mycelium abundant, smooth, white.

Czapek's agar: No growth.

Plain broth: No growth.

Milk: No growth.

Potato: Growth good, raised, folded. No discoloration.

Nitrites not produced from nitrates except a trace in two strains.

Diastatic.

Weakly proteolytic.

Inversion of sucrose: Negative.

Distinctive character: The ability to live in acid media only.

Source: Four strains isolated from three acid humus soils.

Habitat: Acid humus soils.

56. **Streptomyces rubescens** (Jarach) *comb. nov.* (*Streptothrix rubescens* Jarach, Boll. Sez. Ital. Soc. Intern. Microb., *3*, 1931, 43.) From Latin *rubescens*, becoming red.

Gelatin: No liquefaction; limited non-pigmented growth.

Glucose agar: Large number of small round colonies raised in the center and growing together, as well as deep into the medium; of a whitish opalescent color.

Czapek's agar: Poor growth, becoming pigmented salmon-red, edge entire.

Milk agar medium: Rose-coral-colored, thin growth with edge entire.

Broth: Minute flakes, the liquid later becoming reddish-colored.

Milk: No coagulation and no digestion; slight red coloration of milk.

Potato plug: Reddish growth, not extensive; opalescent surface.

Source: From soil.

57. **Streptomyces thermophilus** (Gilbert) *comb. nov.* (*Actinomyces thermophilus* Gilbert, Ztschr. f. Hyg., *47*, 1904, 383; not *Actinomyces thermophilus* Berestnew, Inaug. Diss., Moskow, 1897;

Nocardia thermophila Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 271.) From Greek *thermus*, heat and *philus*, loving.

Description from Waksman, Umbreit and Gordon, Soil Sci., *47*, 1939, 49.

Hyphae straight, conidia formed.

Gelatin: Liquefaction.

Czapek's agar: At 28°C, deep colorless growth, thin white aerial mycelium; no soluble pigment.

Starch agar: Yellowish growth with white-gray, powdery aerial mycelium.

Milk: Proteolysis.

Potato plug: Yellowish growth with no aerial mycelium, the plug usually being colored brown.

Starch is hydrolyzed.

No pigment produced on nutrient agar or gelatin.

Temperature relations: Optimum 50°C. Good growth at 28°C. Usually no growth at 60°C. Some strains are incapable of growing at 28°C, whereas others seem to grow well even at 65°C.

Aerobic.

Habitat: Soil, hay, composts.

58. **Streptomyces thermofuscus** (Waksman, Umbreit and Gordon) *comb. nov.* (*Actinomyces thermofuscus* Waksman, Umbreit and Gordon, Soil Sci., *47*, 1939, 49.) From Greek *thermus*, heat and Latin *fuscus*, dark. Presumably derived to mean heat-loving and dark in color.

Hyphae spiral-shaped; conidia produced.

Gelatin: Liquefaction. At 50°C, a grayish ring is produced and soluble pigment is formed. At 28°C, growth with no soluble pigment.

Czapek's agar: Poor growth at 28°C, deep-gray, with but little aerial mycelium. At 50°C, growth dark to violet, with gray to lavender aerial mycelium and soluble brown pigment.

Milk: Proteolysis.

Potato: Abundant, dark-colored growth, no aerial mycelium, or few white patches, dark soluble pigment.

Starch is hydrolyzed.

Temperature relations: Good growth at 50° and 60°C. Will grow at 65°C. Faint growth at 28°C.

Aerobic.

Distinctive characters: This species is distinguished from *Streptomyces thermophilus* by the brown-colored aerial mycelium on synthetic media, spiral-shaped hyphae, and ability to grow readily at 65°C.

Habitat: Soils and composts.

59. **Streptomyces scabies** (Thaxter) *comb. nov.* (*Oospora scabies* Thaxter, Ann. Rept. Conn. Agr. Exp. Sta., 1891, 153; *Actinomyces scabies* Gussow, Science, N. S. *39*, 1914, 431.) From Latin *scabies*, scab.

Wavy or slightly curved mycelium, with long branched aerial hyphae, showing a few spirals. Conidia more or less cylindrical, 0.8 to 1.0 by 1.2 to 1.5 microns.

Gelatin stab: Cream-colored surface growth, becoming brown. Slow liquefaction.

Synthetic agar: Abundant, cream-colored, wrinkled, raised growth. Aerial mycelium white, scarce.

Starch agar: Thin, transparent, spreading growth.

Glucose agar: Restricted, folded, cream-colored, entire growth.

Plain agar: Circular, entire colonies, smooth, becoming raised, lichenoid, wrinkled, white to straw-colored, opalescent to opaque.

Glucose broth: Ring in form of small colonies, settling to the bottom.

Litmus milk: Brown ring with greenish tinge; coagulated; peptonized with alkaline reaction.

Potato: Gray, opalescent growth, becoming black, wrinkled.

Nitrites produced from nitrates.

Brown soluble pigment formed.

Starch is hydrolyzed.

Optimum temperature 37°C.

Aerobic.

The potato scab organism, like other

acid-fast organisms, can be selectively impregnated with carbol-auromin and when exposed to ultraviolet radiation fluoresces bright yellow. This technic confirms Lutman's conclusion that the hyphae are intercellular and grow within the middle lamellae (Richards, Stain Tech., *18*, 1943, 91–94).

Source: Isolated from potato scab lesions.

Habitat: Cause of potato scab; found in soil.

60. **Streptomyces ipomoea** (Person and Martin) *comb. nov.* (*Actinomyces ipomoea* Person and Martin, Phytopath., *30*, 1940, 313.) From M. L. *Ipomoea*, a generic name.

Conidia on glucose-casein agar: Oval to elliptical, 0.9 to 1.3 by 1.3 to 1.8 microns.

Gelatin: After 25 days at 20°C, scanty growth, no aerial mycelium; no soluble pigment; liquefaction.

Synthetic agar: Abundant growth, mostly on surface of medium, moderately wrinkled, olive-yellow.

Nutrient agar: Moderate growth in the form of small, shiny, crinkled colonies both on the surface and imbedded in the medium, silver-colored.

Starch agar: Growth moderate, smooth, deep in medium, ivory-colored. Aerial mycelium white with patches of bluish-green. No soluble pigment. Complete hydrolysis after 12 days.

Milk: Growth in form of ring; hydrolysis, without visible coagulation.

Potato: Growth moderate, light brown, shiny, wrinkled. No aerial mycelium. No soluble pigment.

Nitrites are produced from nitrates.

Starch is hydrolyzed.

No growth on cellulose.

Source: From diseased sweet-potato (*Ipomoea sp.*) tubers and small rootlets from several localities in Louisiana.

61. **Streptomyces fordii** (Erikson) *comb. nov.* (*Actinomyces fordii* Erikson, Med. Res. Counc. Spec. Rept. Ser. 203, 1935, 15 and 36.) Presumably named for the surgeon who first secured the culture.

Mycelium: Filaments of medium length, no spirals or markedly wavy branches. Short, straight, sparse aerial mycelium. Small oval conidia on potato agar and starch agar.

Gelatin: No visible growth, slight softening in 20 days; half-liquefied after 40 days.

Agar: Small, creamy-golden, ring-shaped colonies, and heaped-up patches, becoming golden-brown in color and convoluted.

Glycerol agar: Extensive, golden-brown, convoluted, thin layer.

Serum agar: Golden-brown ring-shaped and coiled smooth colonies; no liquefaction.

Ca-agar: Yellow, scale-like closely adherent colonies; scattered white aerial mycelium.

Blood agar: Innumerable small yellowish ring-shaped colonies; no hemolysis.

Broth: Few flakes at first; later abundant coherent puffball growth.

Synthetic sucrose solution: Moderate sediment of minute round white colonies.

Synthetic glycerol solution: Light white fluffy colonies, minute and in clusters.

Inspissated serum: Innumerable colorless pinpoint colonies; scant white aerial mycelium; after 15 days colonies large, hollow on reverse side; margin depressed; no liquefaction.

Dorset's egg medium: Minute, cream-colored, elevated colonies, becoming golden-brown, raised, convoluted.

Milk: Coagulated; brownish surface ring.

Litmus milk: No change in reaction.

Potato plug: Yellowish growth in thin line, terminal portion tending to be piled up, scant white aerial mycelium at top of slant; after 12 days, growth abundant, golden-brown, confluent, partly honey-combed, partly piled up.

Starch not hydrolyzed.

Tyrosine agar: Reaction negative.

Source: Human spleen in a case of acholuric jaundice.

62. **Streptomyces africanus** (Pijper and Pullinger) *comb. nov.* (*Nocardia africana* Pijper and Pullinger, Jour. Trop. Med. and Hyg., *30*, 1927, 153; *Actinomyces africanus* Nannizzi, in Pollaci, Tratt. Micopat. Umana, *4*, 1934, 8.) From Latin *Africanus*, relating to Africa.

Description from Erikson, Med. Res. Counc. Spec. Rept. Ser. 203, 1935, 18.

Unicellular branching mycelium forming small dense pink colonies with short straight sparse white aerial mycelium.

Gelatin: Irregular pink flakes; no liquefaction.

Agar: A few flat pink discoid colonies.

Glucose agar: Minute red discrete round colonies and piled up paler pink mass with thin white aerial mycelium.

Glycerol agar: After 2 weeks, small heaped-up colorless masses with pink tinge around the colorless colonies, margin depressed; after 3 weeks, abundant, piled up, pale pink growth.

Ca-agar: After 1 week, small, round, colorless colonies with red centers, margins submerged; after 2 weeks, growth bright cherry-red, confluent, with colorless margin.

Dorset's egg medium: Small colorless blister colonies, partly confluent; becoming wrinkled, depressed into medium; slight liquefaction.

Serum agar: Irregularly round, raised, wrinkled, colorless colonies; becoming dry, pink and flaky; later piled up, brownish, friable.

Inspissated serum: After one week, smooth, round, colorless colonies with submerged margin, in confluent patches pink and pitted into medium; after 2 weeks, medium broken up, slight liquefaction; after 3 weeks, liquid dried up, colonies umbilicated, raised, dry and friable.

Broth: Small pink colonies embedded in coherent flocculent mass.

Synthetic sucrose solution: Small pink granules in sediment after 1 week; colonies of medium size, coherent, after 3 weeks.

Potato agar: Bright red growth, small round colonies with colorless submerged margins, and piled up patches with stiff sparse white aerial mycelium.

Litmus milk: Bright red surface growth, liquid unchanged after one month; liquid opaque reddish-purple after 2 months; hydrolyzed, clear wine-red after 3 months.

Source: From a case of mycetoma of a foot in South Africa.

63. **Streptomyces gallicus** (Erikson) *comb. nov.* (*Actinomyces gallicus* Erikson, Med. Res. Counc. Spec. Rept. Ser. 203, 1935, 36.) From Latin *gallicus*, of the Gauls (French).

Description from Erikson (*loc. cit.*, p. 24).

Mycelium shows lateral highly refractive bodies which appear almost identical with the singly situated spores found in *Micromonospora chalceae*.

Gelatin: Scant irregular pink growth; liquefaction very slow, only slight degree in 20 days.

Agar: A few transparent minute pink colonies; growth becomes partly confluent.

Glucose agar: No growth.

Glycerol agar: No growth.

Czapek's agar: No growth.

Coon's agar: Minute colorless to pinkish colonies.

Ca-agar: Glossy pink pinhead colonies.

Potato agar: Pale pink, moist, granular growth.

Serum agar: Pinpoint colonies, pink, shining.

Blood agar: Abundant growth, minute, discrete, round, pink colonies, some aggregated in confluent narrow bands. No hemolysis.

Dorset's egg medium: Minute colonies, becoming confluent, tangerine-colored.

Inspissated serum: Abundant, pink, membranous growth, becoming reddish-brown; later discrete colonies at margin, clear on reverse side. No liquefaction.

Broth: Pinkish flakes.

Synthetic sucrose solution: A few fine white flocculi.

Synthetic glycerol solution: A few small round white colonies.

Milk: Coagulated; peptonized; yellowish-pink surface ring.

Litmus milk: No coagulation or peptonization; no change in color.

Potato plug: Very slow growth, a few minute translucent pink colonies after 16 days; after 21 days, considerable increase in number of colonies, still small and discrete. After 2 months, colonies 1 to 2 mm in diameter, bright coral, tending to be umbilicated and heaped up.

Tyrosine agar: Reaction negative.

Source: From blood culture in a case of Banti's disease.

64. **Streptomyces pelletieri** (Laveran) *comb. nov.* (*Micrococcus pelletieri* Laveran, Compt. rend. Soc. Biol., Paris, *61*, 1906, 340; *Oospora pelletieri* Thiroux and Pelletier, Bull. Soc. path. exot., *5*, 1912, 585; *Nocardia pelletieri* Thiroux, see Pinoy, Bull. Inst. Past., *11*, 1913, 935; *Discomyces pelletieri* Brumpt, Précis de Parasitol., Paris, 2nd ed., 1913, 970; *Actinomyces pelletieri* Brumpt, *ibid.*, 4th ed., 1927, 1204.) Named for M. Pelletier who first isolated this species.

Description from Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 21.

Thiroux and Pelletier (Bull. Soc. path. exot., *5*, 1912, 585) considered that their cultures resembled *Nocardia madurae*, but they grew the organism only on Sabouraud's gelatin, on which it appeared in a constantly red, easily detachable form. *Nocardia indica* was regarded as identical by Pinoy, although in the original description by Laveran the organism was called *Micrococcus pelletieri*, owing to the fact that no mycelium was seen, merely coccoid bodies. *Nocardia genesii* Froes (Bull. Inst. Past., *29*, 1931; 1158) is described as closely allied, the distinction being founded upon the fact that the red grains were smaller in size and much more numerous, but no cultural details are given.

Mycelium composed of slender straight and not very long filaments, forming small dense pink colonies with a few short straight isolated aerial branches.

Gelatin: Slight liquefaction; few pink flakes; later almost completely liquefied.

Agar: Minute colorless colonies and piled up pale pink masses.

Glucose agar: Poor growth, a few minute pink colonies.

Glycerol agar: Poor growth, a few moist pink colonies.

Ca-agar: Colorless small colonies; after 1 week, confluent skin, pink, buckled; medium discolored later.

Coon's agar: Poor growth, cream-colored with pink center, mostly submerged.

Potato agar: Colorless blister colonies; after 3 weeks, colonies larger, showing concentric zones, submerged margins and occasional zone or tuft of white aerial mycelium, pinkish coloration.

Dorset's egg medium: Abundant, wrinkled, pink skin with small discrete colonies at margin in six days; later surface rough, mealy; considerable liquefaction in 17 days.

Serum agar: Moist cream-colored growth tending to be heaped up, discrete colonies at margin; becoming umbilicated.

Inspissated serum: Round, moist, colorless colonies.

Blood agar: At first a few pinhead, cream-colored colonies, no hemolysis; later colonies dense, button-shaped, with narrow fringed margin.

Broth: Small, minute, pink, clustered colonies.

Synthetic sucrose solution: Small, pink colonies in sediment; later minute colonies adhering to side of tube.

Milk: Soft curd; half-digested; peptonization complete in 20 days.

Litmus milk: Pink surface growth, semi-solid, no color change; after 20 days, coagulum cleared, liquid purple.

Potato plug: After one month growth sparse, yellowish-pink, irregularly piled up, portions with scant white aerial mycelium; after 6 months abundant highly piled up small rounded pink

masses, scant white aerial mycelium persistent.

Source: From a case of crimson-grained mycetoma in Nigeria (E. C. Smith, Trans. R. Soc. Trop. Med. Hyg., *22*, 1928, 157).

Habitat: Human infections so far as known.

65. **Streptomyces listeri** (Erikson) *comb. nov.* (*Actinomyces listeri* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 36.) Named for Dr. Joseph Lister, the father of antiseptic surgery.

Description from Erikson (*loc. cit.*, p. 23).

Long slender filaments, many loosely wavy, forming a dense spreading mycelium which rapidly grows into a membrane on most media. Aerial mycelium very slow and inconstant in appearance, short and straight, conidia oval.

Gelatin: Slight liquefaction; round white surface colonies; after 45 days, confluent skin, almost completely liquefied.

Agar: Smooth, round, moist, cream-colored, margin depressed, center elevated, closely adherent; becoming umbilicated, with a myceloid margin.

Glucose agar: Cream-colored, glistening, pinpoint colonies; later aggregated in convoluted skin.

Glycerol agar: Abundant, moist, cream-colored growth, colonies elevated, piled up; powdery white aerial mycelium. After 20 days, skin deeply buckled; colorless with exuded drops.

Ca-agar: Poor growth, a slight biscuit-colored membrane.

Potato agar: After one week, extensive growth, colorless submerged colonies, warted surface; dirty pink coloration after 2 weeks; scant white aerial mycelium after 4 months.

Dorset's egg medium: No growth.

Blood agar: Small, round, cream-colored colonies, smooth translucent surface; no hemolysis.

Serum agar: Small, irregular, moist, cream-colored colonies, tending to be heaped up; later somewhat transparent.

Inspissated serum: Abundant growth, colorless shiny colonies, centrally elevated, becoming confluent.

Broth: Small, round, white colonies in sediment.

Glucose broth: Small, white, nodular colonies; later abundant flocculi.

Synthetic sucrose solution: Delicate white colonies in suspension and in sediment.

Litmus milk: Coagulation. No change in reaction.

Potato plug: Abundant, dull, brownish, wrinkled skin with white aerial mycelium; large, stellate, fluffy, white colonies in liquid at base.

Source: From human material. Strain from Lister Collection.

Habitat: From human infections so far as known.

66. **Streptomyces upcottii** (Erikson) *comb. nov.* (A new pathogenic form of *Streptothrix*, Gibson, Jour. Bact. and Path., *23*, 1920, 357; *Actinomyces upcottii* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 36.) Named for Dr. Harold Upcott, the surgeon who first secured the culture.

Description from Erikson (*loc. cit.*, p. 22).

Filaments characteristically long, straight, much interwoven and ramified; typical unicellular mycelium, usually forming medium to large heavy cartilaginous colonies. Gibson states that the threads vary in thickness and show septa, but this has not been confirmed. A very slight transient aerial mycelium appeared on one agar slope, but this has not been repeated on any slide microculture on any medium. Slightly acid-fast.

Gelatin: Abundant flocculent growth along streak, round cream-colored colonies on surface. Partly liquefied in 14 days; complete liquefaction in 2 months.

Agar: Smooth, shining, round, cream-colored colonies, margin submerged,

scant white aerial mycelium in one week; colonies large (up to 10 mm in diameter), centers elevated, greenish tinge, very sparse aerial mycelium in two weeks; the aerial mycelium disappears and large radial grooves appear in most colonies in 3 weeks.

Glucose agar: Smooth, round, cream-colored colonies, margin depressed, centers elevated, hollow on reverse side; later a coherent membranous growth, piled up, yellowish.

Glycerol agar: Small, round, cream-colored, glistening colonies, heavy texture, margins submerged; later, colonies umbilicated, tending to be piled up; after 6 weeks, growth very much convoluted and raised, broad submerged margin, slightly reddish medium.

Coon's agar: Small, radiating, white colonies, growth mostly submerged.

Ca-agar: Small, colorless membranous growth with undulating margin; later, centrally depressed into medium.

Potato agar: Poor growth, small, colorless blister colonies, medium slightly discolored.

Dorset's egg medium: Round, flat, colorless, scale-like colonies, some marked by concentric rings and slightly hollowed in center; growth becomes yellow-brown.

Serum agar: Large colonies (3 to 4 mm in diameter), colorless, granular, centrally elevated, depressed at margin, resembling limpets.

Blood agar: Large drab heavily textured colonies; no aerial mycelium; no hemolysis.

Broth: Large coherent mass composed of fluffy colonies.

Synthetic sucrose solution: Fair growth, minute white colonies.

Carrot plug: Colorless, spreading, moist, wrinkled growth in six weeks; later a dull greenish-brown, moist, very much wrinkled and depressed skin.

Source: From the spleen in a case of acholuric jaundice.

Habitat: From human infections so far as known.

67. **Streptomyces hortonensis** (Erikson) *comb. nov.* (*Actinomyces horton* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 36.) Named for the Horton War Hospital at Epsom, England from which the culture was obtained.

Description from Erikson (*loc. cit.*, p. 22).

Typical germination into very slow growing unicellular mycelium composed of long slender straight branching filaments. Very sparse straight aerial mycelium produced only once on potato. Non-acid-fast.

Gelatin: Round cream-colored colonies on surface and a few mm below. No liquefaction.

Agar: Very slow growth, a few smooth cream-colored coiled colonies in 19 days; after 2 months, liberal, irregular, convoluted growth.

Glucose agar: Coiled and heaped up cream-colored translucent masses; after 2 months, growth rounded, elevated, ridged outwards from hollow center.

Glycerol agar: Coiled, colorless, lustrous patches, isolated colony with central depression.

Serum agar: Poor growth, small amorphous cream-colored mass.

Inspissated serum: Intricately coiled cream-colored growth. No liquefaction.

Broth: Flakes.

Synthetic sucrose solution: Poor growth, a few flakes.

Synthetic glycerol solution: Delicate white flocculi at base.

Litmus milk: Green surface growth, liquid hydrolyzed, partly clear purple; later decolorized, brown.

Potato agar: Colorless blister colonies in one week; dull green heaped and coiled mass after 3 weeks; medium becomes slightly discolored.

Potato plug: After 3 weeks, abundant, colorless, umbilicated, round colonies, some coiled in raised masses; later, liberal olive-green growth, piled up, dense, velvety gray-green aerial mycelium at top of slant, small round fluffy white colonies in liquid at base.

Source: From pus containing typical actinomycotic granules from parotid abscess.

Habitat: From human infections so far as known.

68. **Streptomyces gibsonii** (Erikson) *comb. nov.* (*Actinomyces gibsonii* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 36.) Named for Prof. Gibson of Oxford.

Description from Erikson (*loc. cit.*, p. 15).

Young growing mycelium branches profusely at short intervals; later grows out into long frequently wavy filaments; twisted hyphae also seen on water agar. Power of producing aerial mycelium apparently lost.

Gelatin: Dull white flakes sinking as medium liquefies; liquefaction complete in 12 days.

Agar: Small, cream-colored, depressed, partly confluent colonies, becoming an extensive wrinkled cream-colored skin.

Glucose agar: Cream-colored wrinkled membranous growth.

Potato agar: Wrinkled glistening membranous growth.

Serum agar: Small moist cream-colored colonies growing into medium.

Dorset's egg medium: Small, round, smooth, colorless colonies with conically elevated centers.

Inspissated serum: Innumerable colorless pinpoint colonies with scant white aerial mycelium at top; after 8 days, a coherent wrinkled skin with brownish-red discoloration at reverse, medium becoming transparent; completely liquefied, pigmented brown in 15 days.

Blood agar: Yellowish confluent bands, irregularly wrinkled, with small discrete colonies, clear hemolytic zone.

Broth: Sediment of flocculi, some round and fan-shaped colonies.

Synthetic sucrose solution: Very delicate white flocculi.

Potato plug: No growth.

Starch not hydrolyzed.

Milk: Coagulated; partly peptonized.

Tyrosine agar: Negative reaction.

Source: From the spleen in a case of acholuric jaundice. Injected into a monkey, and reisolated.

Habitat: From human infections so far as known.

69. **Streptomyces beddardii** (Erikson) *comb. nov.* (*Actinomyces beddardii* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 36.) Presumably named for the surgeon who first secured the culture.

Description from Erikson (*loc. cit.*, p. 13).

Rapidly growing, dense, spreading mycelium composed of very long slender filaments, many wavy or closely coiled, particularly on glucose agar; spirals less marked or lacking on poorer nutritive media like synthetic glycerol agar or water agar. Aerial mycelium sparse, short, straight on synthetic glycerol agar, much slower and more plentiful on glucose agar; later shows long, very fine spirals breaking up into small oval conidia; aerial hyphae straighter and more branched with shorter conidiophores on starch agar. Non-acid-fast.

Gelatin: Dull white flakes sinking to bottom as medium liquefies; liquefaction complete in 8 days.

Agar: Colorless, coherent, wrinkled, membranous growth with submerged margin; after 3 months, medium discolored, scant white aerial mycelium at top.

Glucose agar: Wrinkled membranous growth; after 2 months, scant white aerial mycelium.

Glycerol agar: Small, cream-colored, discrete colonies becoming confluent, under surface much buckled.

Potato agar: Moist, cream-colored skin, convoluted, closely adherent.

Ca-agar: Extensive, moist, cream-colored, wrinkled, membranous growth.

Coon's agar: Scant, cream-colored, membranous growth.

Starch agar: Spreading, colorless growth, considerable white aerial mycelium.

Blood agar: Hemolysis. Growth in uniformly striated colorless bands, occasional round colonies at margin.

Dorset's egg medium: Extensive, very wrinkled, membranous growth, surface bright yellow. After 2 months, considerable liquefaction.

Serum agar: Wrinkled, glistening, cream-colored, membranous growth.

Inspissated serum: Colorless smeary growth, reverse becoming transparent, starting to liquefy at base; completely liquefied and brown in 12 days.

Broth: Suspended and sedimented colorless flocculi, some small round colonies.

Synthetic sucrose solution: Abundant white colonies in coherent mass near bottom of tube; large shell-shaped masses.

Synthetic glycerol solution: At first, a few round white colonies in suspension; later, large branched feathery mass at bottom.

Milk: Coagulated; later peptonized.

Litmus milk: Medium deep blue, becoming hydrolyzed to clear purple.

Potato plug: Colorless moist membranous growth with scant white aerial mycelium at top of plug.

Starch is hydrolyzed.

Tyrosine agar: Reaction negative.

Source: Human spleen in a case of spleenic anemia.

Habitat: From human infections so far as known.

70. **Streptomyces kimberi** (Erikson) *comb. nov.* (*Actinomyces kimberi* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 36.) Presumably named for the surgeon who first secured the culture.

Description from Erikson (*loc. cit.*, p. 14).

Mycelium of long straight profusely branching filaments forming circumscribed colonies on all media with abundant production of short straight and branched aerial mycelium; small round conidia. Non-acid-fast.

Gelatin: Liquefied. Smooth shining colonies becoming powdery white with aerial mycelium, floating on liquefied medium. No pigmentation.

Agar: Smooth round moist cream-colored colonies, 1 mm in diameter; after 17 days, white powdery aerial mycelium.

Glucose agar: Discrete cream-colored colonies becoming confluent, white aerial mycelium.

Glycerol agar: Moist cream-colored colonies becoming confluent, white aerial mycelium.

Potato agar: Extensive growth covered by white powdery aerial mycelium; large colorless exuded droplets.

Wort agar: Heavy brownish lichenoid colony; after 30 days, a white aerial mycelium.

Ca-agar: Dull cream-colored scaly growth, covered by chalky white aerial mycelium.

Coon's agar: Extensive growth, white aerial mycelium in annular arrangement.

Czapek's agar: Small colonies covered with white aerial mycelium.

Blood agar: Many large colonies, cream-colored, tough, smooth, glistening, with margin depressed; no hemolysis.

Serum agar: Moist, cream-colored honeycombed skin, scant white aerial mycelium.

Dorset's egg medium: Closely adherent scale-like colonies, centrally elevated, with white aerial mycelium.

Inspissated serum: Rapid spreading growth, discrete round colonies at margin, completely covered with white aerial mycelium, colorless transpired drops; slight softening at base.

Broth: Small round colonies in sediment in 2 days; supernatant colonies with white aerial mycelium and large hollow flakes in sediment in 15 days; occasional reddish-brown coloration.

Synthetic sucrose solution: Round white colonies at bottom; later small stellate colonies in suspension and a few supernatant with white aerial mycelium.

Synthetic glycerol solution: Round white colonies at bottom; later coherent mulberry-like mass composed of fluffy

round portions; after 15 days, irregular wispy flocculi and large coherent mass.

Milk: Coagulation; no peptonization; initial pinkish-brown ring descends until medium is dark brown throughout (2 months).

Litmus milk: Blue coloration, hydrolyzed to clear purple in 2 months.

Starch not hydrolyzed.

Tyrosine agar: Reaction negative.

Source: Blood culture of a woman with acholuric jaundice.

Habitat: From human infections so far as known.

71. **Streptomyces somaliensis** (Brumpt) *comb. nov.* (*Indiella somaliensis* Brumpt, Arch. Parasit., Paris, *10*, 1906, 489; *Discomyces somaliensis* Brumpt, Précis de Parasitologie, Paris, 2nd ed., 1913, 967; *Indiellopsis somaliensis* Brumpt, *ibid.*; *Nocardia somaliensis* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 239; *Streptothrix somaliensis* Miescher, Arch. Derm. Syphilis, *124*, 1917, 297; *Actinomyces somaliensis* St. John-Brooks, Med. Res. Council Syst. of Bact., London, *8*, 1931, 75.) Named for the country of origin, French Somaliland.

Description from Erikson (Med. Res. Council Spec. Rept. Ser. 203, 1935, 17).

Simple branching unicellular mycelium with long straight filaments, forming circumscribed colony crowned with short straight aerial mycelium.

Gelatin: Cream-colored colonies, medium pitted; complete liquefaction in 10 days; hard black mass at bottom.

Agar: Abundant yellowish granular growth with small discrete colonies at margin; later growth colorless, colonies umbilicated.

Glucose agar: Poor growth, moist cream-colored elevated patch.

Glycerol agar: Abundant growth, minute round to large convoluted and piled up masses, colorless to dark gray and black.

Ca-agar: Round cream-colored colonies, depressed, umbilicated, piled up, thin white aerial mycelium; colonies become pale brown.

Potato agar: Small round colorless colonies, zonate margin depressed, confluent portion dark greenish-black.

Blood agar: Small dark brown colonies, round and umbilicated, piled up confluent bands, reverse red-black; hemolysis.

Dorset's egg medium: Extensive colorless growth, partly discrete; becoming opaque, cream-colored, very wrinkled; later rough, yellow, mealy, portion liquid.

Serum agar: Spreading yellow-brown skin, intricately convoluted.

Inspissated serum: Cream-colored coiled colonies, medium pitted, transparent and slightly liquid.

Broth: A few round white colonies at surface, numerous fluffy masses in sediment; later large irregular mass breaking into wisps.

Synthetic sucrose solution: Minute round white fluffy colonies in sediment; after 17 days, scant wispy growth.

Milk: Soft semi-liquid coagulum which undergoes digestion; heavy wrinkled surface pellicle, completely liquefied in 12 days.

Litmus milk: Soft coagulum, partly digested, blue surface ring; clear liquid in 12 days.

Potato plug: Abundant growth, colonies round and oval, partly piled up in rosettes, frosted with whitish-gray aerial mycelium, plug discolored; after 16 days, aerial mycelium transient, growth nearly black.

Although *Streptomyces somaliensis* has been known for a long time, there has been until recently no detailed descriptions of the organism beyond the fact that it possesses a distinctly hard sheath around the grain which is insoluble in potash and eau de javelle. The rare occurrence of septa and occasional intercalary chlamydospores is reported by Brumpt (Arch. Parasit., *10*, 1905, 562), but has not been confirmed by Erikson (*loc. cit.*). Chalmers and Christopherson (Ann. Trop. Med. Parasit., *10*, 1916, 223)

merely mentioned the growth on potato as yellowish-white and lichenoid without describing any aerial mycelium. Balfour in 1911 reported a case but gave no data, and Fülleborn limited his description to the grain (Arch. Schiffs. Trop. Hyg., *15*, 1911, 131). This species was first placed in *Indiella*, a genus of fungi, by Brumpt (1906, *loc. cit.*). Later Brumpt (1913, *loc. cit.*) proposed a new genus or subgenus, *Indiellopsis*, containing the single species *Indiellopsis somaliensis*.

Source: Yellow-grained mycetoma, Khartoum (Balfour, 4th Rept. Wellcome Trop. Res. Lab., A. Med., London, 1911, 365).

Habitat: This condition has been observed by Baufford in French Somaliland, by Balfour (*loc. cit.*) in the Anglo-Egyptian Sudan, by Fülleborn (*loc. cit.*) in German So. West Africa and by Chalmers and Christopherson (*loc. cit.*) in the Sudan.

72. **Streptomyces panjae** (Erikson) *comb. nov.* (*Actinomyces panja* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 36.) Named for Dr. Panja who first secured the culture.

Description from Erikson (*loc. cit.*, p. 16).

Unicellular mycelium with slender branching filaments; very small round colonies; no aerial mycelium visible on any medium, but occasional isolated aerial branches. Non-acid-fast.

Gelatin: Complete liquefaction in 4 days.

Agar: Colorless irregularly piled up convoluted growth; after 1 month, easily detachable, brownish.

Glucose agar: Small colorless coiled mass in 1 week; heaped up green growth in 2 weeks.

Glycerol agar: Poor growth, scant colorless patch.

Ca-agar: Colorless to pink spreading growth with minute discrete colonies at margin; after 2 weeks, bright red mass, buckled and shining, colorless submerged margin.

Coon's agar: Small submerged colorless growth.

Potato agar: Small elevated convoluted colorless masses with purple tinge in center.

Dorset's egg medium: Small round tough colorless colonies, margin well embedded; after 3 weeks, colonies elevated, warted, darkened, medium discolored and broken; slight degree of liquefaction, medium dark brown.

Serum agar: Colorless, glistening, piled up, convoluted mass.

Inspissated serum: Small round blister colonies and irregularly convoluted patches deeply sunk in pitted medium; after 2 weeks, medium transparent, slight degree of liquefaction.

Broth: Flakes and minute colorless colonies.

Glucose broth: Poor growth, scant flakes, pinkish.

Synthetic sucrose solution: Pinkish flocculi; after 3 weeks, moderate growth, minute colorless colonies.

Milk: Coagulation; pale green surface growth; mostly digested in 2 weeks.

Litmus milk: Soft coagulum, color unchanged; after 2 months, mostly digested, residue coagulum light purple.

Source: From an ulcer of the abdominal wall, Calcutta.

73. **Streptomyces willmorei** (Erikson) *comb. nov.* (*Actinomyces willmorei* Erikson, Med. Res. Council Spec. Rept. Ser. 203, 1935, 36.) Named for Dr. Willmore who isolated the culture.

Description from Erikson (*loc. cit.*, p. 19).

Germination usual, but growing unicellular mycelium frequently branches at very short intervals, presenting peculiar clubbed and budding forms with occasional separate round swollen cells which may represent the cystites of other writers. The filaments are characteristically long, homogeneous, and much interwoven. Aerial mycelium is profuse

in most media, with a marked tendency to produce loose spirals (water and synthetic glycerol agar) with chains of ellipsoidal conidia. Thick aerial clusters may also be formed.

Gelatin: Minute colorless colonies; liquefaction.

Agar: Heavy folded colorless lichenoid growth, rounded elevations covered with white aerial mycelium; later, submerged margin, round confluent growth, aerial mycelium marked in concentric zones.

Glucose agar: Colorless wrinkled confluent growth with smooth entire margin, large discrete colonies like flat rosettes; after 4 months, scant white aerial mycelium.

Glycerol agar: Round smooth cream-colored colonies, heavy texture, margin submerged, stiff sparse aerial spikes; after 3 weeks, colonies large (up to 10 mm in diameter).

Ca-agar: Spreading colorless growth, pitting medium, submerged undulating margin; very scant white aerial mycelium.

Coon's agar: Opaque white growth extending irregularly (up to 3 mm) into medium, margin smooth and submerged, center raised, greenish tinge covered with white aerial mycelium; after 3 weeks, margin green, central mass covered by gray aerial mycelium.

Potato agar: Fair growth, partly submerged, covered with grayish-white aerial mycelium; medium becomes discolored.

Blood agar: Heavily textured small drab colonies, aerial mycelium microscopical; no hemolysis.

Dorset's egg medium: Large, round, colorless, scale-like colonies, radially wrinkled; growth brownish, medium discolored in 2 weeks.

Serum agar: Smooth colorless discoid colonies; marked umbilication after 2 weeks.

Broth: Large fluffy white hemispherical colonies, loosely coherent.

Synthetic sucrose solution: A few large round white colonies with smooth partly zonate margins, lightly coherent in sediment; later smaller colonies in suspension attached to side of tube.

Milk: Coagulation; one-third peptonized.

Carrot plug: Colorless raised colonies with powdery white aerial mycelium; after 1 month, very much piled up, aerial mycelium gray; after 2 months, superabundant growth around back of plug, confluent, greatly buckled, all-over gray aerial mycelium.

Source: Streptothricosis of liver (Willmore, Trans. Roy Soc. Trop. Med. Hyg., *17*, 1924, 344).

Habitat: From human infections so far as known.

***Appendix:** The following names have been used for species of *Streptomyces*. Many of them are regarded as new by their authors merely because they were isolated from a new type of lesion, or from some animal other than man. Others are inadequately described species from air, soil or water. Relationships to other better described species are usually very obscure. Some of the species listed here may belong in the appendix to the genus *Nocardia*.

Actinomyces aerugineus Wollenweber. (Arb. d. Forschungsinst. f. Kartoffelbau, 1920, 16.) From deep scab on potato.

Actinomyces albidofuscus Neukirch. (*Actinomyces albido fuscus* Berestnew, Inaug. Diss., Moskow, 1897; see Cent. f. Bakt., I Abt., *24*, 1898, 707; Neukirch, Inaug. Diss., Strassburg, 1902, 3.) From grain.

Actinomyces albidus Duché. (Encyclopédie Mycologique, Paris, *6*, 1934, 266.)

Actinomyces alboatrus Waksman and

*** This appendix was originally prepared by Prof. S. A. Waksman and Prof. A. T. Henrici, May, 1943; it has been developed further by Mrs. Eleanore Heist Clise, Geneva, New York, August, 1945.**

Curtis. (Soil Science, *1*, 1916, 117.) From adobe soil.

Actinomyces alboviridis Duché. (Encyclopédie Mycologique, Paris, *6*, 1934, 317.)

Actinomyces albus (Rossi Doria) Gasperini. (*Streptotrix* (sic) *alba* Rossi Doria, Ann. d. Ist. d'Ig. sper. d. Univ. di Roma, *1*, 1891, 421; Streptothrix Nos. 2 and 3, Almquist, Ztschr. f. Hyg., *8*, 1890, 189; *Oospora doriae* Sauvageau and Radais, Ann. Inst. Past., *6*, 1892, 251; *Actinomyces bovis albus* Gasperini, Atti Soc. Tosc. Scienz. Nat., P. V., *9*, 1894; Gasperini, Cent. f. Bakt., *15*, 1894, 685.) A general name applied to the most common streptomyces in air and water.

Actinomyces albus asporogenes Berestnew. (Inaug. Diss., Moskow, 1897; see Cent. f. Bakt., I Abt., *24*, 1898, 708.)

Actinomyces albus var. *ochraleucus* Wollenweber. (Arb. d. Forschungsinst. für Kartoffelbau, 1920, 16.)

Actinomyces albus - vulgaris Ciani. (Quoted from Baldacci, Boll. Sez. Ital. Soc. Internaz. di Microbiol., *9*, 1937, 140.)

Actinomyces almquisti Duché. (Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 278.) From culture labeled *Actinomyces albus* (Krainsky) Waksman and Curtis (Soil Sci., *1*, 1916, 117; said to resemble *Streptothrix* No. 1, Almquist, Ztschr. f. Hyg., *8*, 1890, 189).

Actinomyces alni Peklo. (Cent. f. Bakt., II Abt., *27*, 1910, 451.) From swellings of the roots of *Alnus glutinosa*.

Actinomyces annulatus Wollenweber. (Arb. Forschungsinst. für Kartoffelbau, 1920, 16.) From dark-colored potato stem.

Actinomyces (*Streptothrix*) *annulatus* Beijerinck. (Folia Microbiologica, *1*, 1912, 4.)

Actinomyces aurea (du Bois Saint Sévérin) Ford. (*Streptothrix aurea* du Bois Saint Sévérin, Arch. de méd. nav., 1895, 252; *Nocardia aurea* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 818; *Oospora aurea* Sartory, Champ. Paras. Homme et Anim., 1923, 818; Ford, Textb. of Bact., 1927, 220; not *Actinomyces aureus* Waksman and Curtis, Soil Science, *1*, 1916, 124.) Possibly synonymous with *Actinomyces aureus* Lachner-Sandoval, Die Strahlenpilze, 1893, according to Lieske, Morphol. u. Biol. d. Strahlenpilze, Leipzig, 1921, 26. Found in conjunctivitis.

Actinomyces bellisari Dodge. (*Streptothrix alba* Bellisari, Ann. Ig. Sperim., *14*, 1904, 467; *Oospora alba* Sartory, Champ. Paras. Homme et Anim., 1923, 819; Dodge, Medical Mycology, St. Louis, 1935, 744.) Isolated in a warehouse in Naples from the dust of cereal coming from California.

Actinomyces bovis var. *nigerianus* Erikson. (Med. Res. Council Spec. Rept. Ser. 203, 1935, 20 and 36.) From streptothricosis of the skin of cattle in Nigeria.

Actinomyces candidus (Petruschky) Bergey et al. (*Streptothrix candida* (Gedanensis II) Petruschky, Verhandl. d. Kongr. f. innere Med., 1898; see Petruschky, in Kolle and Wassermann, Handb. d. path. Mikroorg., 2 Aufl., *5*, 1913, 285 and 294; *Nocardia candida* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 818; *Discomyces candidus* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 980; Bergey et al., Manual, 1st ed., 1923, 347.) From human lung.

Actinomyces carneus (Rossi Doria) Gasperini. (*Streptotrix carnea* Rossi Doria, Ann. Ist. d'Ig. sper. Univ. Roma, *1*, 1891, 415; Gasperini, *ibid.*, *2*, 1892, 222; *Oospora carnea* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 388; *Cladothrix carnea* Macé, Traité Pratique de Bact., 4th ed., 1901, 1096; *Discomyces carneus* Brumpt, Précis de Parasitol., 2nd ed., 1913, 976; *Nocardia carnea* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 818.) From air.

Actinomyces carnosus Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato.

Actinomyces casei Bernstein and Morton. (Jour. Bact., *27*, 1934, 625.) Thermophilic. From pasteurized cheese.

Actinomyces cati (Rivolta) Gasperini. (*Discomyces cati* Rivolta, 1878; Gasperini, Cent. f. Bakt., *15*, 1894, 684.) Cause of a disease in a cat.

Actinomyces cerebriformis Namyslowski. (Namyslowski, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 564; *Streptothrix cerebriformis* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 273; *Nocardia cerebriformis* Vuillemin, Encyclopédie Mycologique, Paris, *2*, 1931, 126.) From an infection of the cornea of the human eye.

Actinomyces cereus. (Quoted from Lieske, Morphol. u. Biol. d. Strahlenpilze, Leipzig, 1921, 33.)

Actinomyces chromogenus (Gasperini) Gasperini. (*Streptotrix nigra* Rossi Doria, Ann. d. Ist. d'Ig. sper. d. Univ. di Roma, *1*, 1891, 419; *Streptotrix cromogena* (sic) Gasperini, according to Rossi Doria, *idem*; Gasperini, *ibid.*, *2*, 1892, 222; *Oospora chromogenes* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 389; *Cladothrix chromogenes* Macé, Traité Pratique de Bact., 4th ed., 1901, 1075; *Actinomyces niger* Brumpt, Précis de Parasitol., Paris, 4th ed., 1927, 1206.) A general name for streptomyces from air producing a dark chromogenesis on protein media.

Actinomyces cinereonigeraromaticus Neukirch. (*Actinomyces cinereus niger aromaticus* Berestnew, Inaug. Diss., Moskow, 1897; see Cent. f. Bakt., I Abt., *24*, 1898, 707; Neukirch, Inaug. Diss., Strassburg, 1902, 3; *Nocardia cinereonigra* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 271; *Streptothrix cinereonigra aromatica*, attributed to Berestnew by Chalmers and Christopherson, *idem*; *Actinomyces cinereo-niger*, quoted from Lieske, Morphol. u. Biol. d. Strahlenpilze, Leipzig, 1921, 33.) From grain.

Actinomyces citreus Gasperini. (Gasperini, Cent. f. Bakt., *15*, 1894, 684; *Streptothrix citrea* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 63; not *Actinomyces citreus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662.)

Actinomyces clavifer Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato and from soil.

Actinomyces coroniformis Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From peat soil.

Actinomyces craterifer Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato.

Actinomyces cloacae Brussoff. (Cent. f. Bakt., II Abt., *49*, 1919, 97.) From mud.

Actinomyces cretaceus (Krüger) Wollenweber. (*Oospora cretacea* Krüger, Berichte der Versuchsstat. f. Zuckerrohrs, Kergok-Legal, 1890; Wollenweber, Arbeiten d. Forschungsinstitut für Kartoffelbau, 1920, 16.) From potato scab.

Actinomyces dicksonii Erikson. (Med. Res. Council Spec. Rept. Ser. 203, 1935, 17.)

Actinomyces elastica Söhngen and Fol. (Cent. f. Bakt., II Abt., *40*, 1914, 92.) From garden earth.

Actinomyces ferrugineus Naumann. (Kungl. Svenska Vetenskapsakad. Handl., I, *62*, Part 4, 1921, 45.) From Aneboda region of Sweden. Deposits ferric hydroxide about the mycelial threads.

Actinomyces filiformis (Boas) Nannizzi. (*Bacillus filiformis* Boas, 1897; not *Bacillus filiformis* Tils. Ztschr. f. Hyg., *9*, 1890, 294; not *Bacillus filiformis* Migula, Syst. d. Bakt., *2*, 1900, 387; *Nocardia filiformis* Vuillemin, Encyclopédie Mycologique, Paris, *2*, 1931, 132; Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 26.) From the human stomach.

Actinomyces fimbriatus Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato.

Actinomyces flavegriseus Duché. (Encyclopédie Mycologique, Paris, *6*, 1934, 341.) From volcanic soils (Martinique).

Actinomyces flavus Sanfelice. (Sanfelice, Cent. f. Bakt., I Abt., Orig., *36*, 1904, 359; *Streptothrix flava* Sanfelice, *ibid.*; not *Streptothrix flava* Chester, Manual Determ. Bact., 1901, 362; not *Actinomyces flavus* Krainsky, Cent. f.

Bakt., II Abt., *41*, 1914, 662.) From air.

Actinomyces flavus Millard and Burr. (Millard and Burr, Ann. Appl. Biol., *13*, 1926, 601; not *Actinomyces flavus* Sanfelice, Cent. f. Bakt., I Abt., Orig., *36*, 1904, 359; not *Actinomyces flavus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; not *Actinomyces flavus* Dodge, Medical Mycology, St. Louis, 1935, 752.) From scab on potato.

Actinomyces foersteri (Cohn) Gasperini. (*Streptothrix foersteri* Cohn, Beitr. z. Biol. d. Pflanz., *1*, Heft 3, 1875, 186; *Cladothrix foersteri* Winter, Die Pilze, in Rabenhorst's Kryptogamen-Flora, I Abt., *1*, 1884, 60; *Nocardia foersteri* Trevisan, I generi e le specie delle Batteriacee, 1889, 9; *Oospora foersteri* Sauvageau and Radais, Ann. Inst. Past., *6*, 1892, 252; Gasperini, Cent. f. Bakt., *15*, 1894, 684; *Discomyces foersteri* Gedoelst, Les champignons parasites de l'homme et des animaux domestiques. Brussels, 1902, 176; *Cohnistreptothrix foersteri* Pinoy, Bull. Inst. Pasteur, Paris, *11*, 1913, 937.) The first streptomyces to be described. Probably not identifiable. From an inflamed tear duct. Chalmers and Christopherson (Ann. Trop. Med. and Parasit., *10*, 1916, 273) include *Leptothrix oculorum* Sorokin, 1881 as a synonym of this species.

Actinomyces fusca Söhngen and Fol. (Cent. f. Bakt., II Abt., *40*, 1914, 87.) From garden earth.

Actinomyces gabritschewskii Neukirch. (*Actinomyces* of Gabritschewsky, Berestnew, Inaug. Diss., Moskow, 1897; see Cent. f. Bakt., I Abt., *24*, 1898, 708; Neukirch, Inaug. Diss., Strassburg, 1902, 3.) From water.

Actinomyces gedanensis (Löhlein) Bergey et al. (*Streptothrix gedanensis I*, Scheele and Petruschky, Verhandl. d. Kongr. f. innere Med., 1897, 550; *Streptothrix gedanensis* Löhlein, Ztschr. f. Hyg., *63*, 1909, 11; *Nocardia gedanensis* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 255; *Discomyces gedanensis* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 984; Bergey et al., Manual, 1st ed., 1923, 347.) From sputum of patient with chronic lung disease.

Actinomyces gibsoni Dodge. (*Streptothrix sp.* Gibson, Jour. Path. Bact., *23*, 1920, 357; *Oospora sp.* Sartory, Champ. Paras. Homme et Anim., 1923, 776; Dodge, Medical Mycology, St. Louis, 1935, 722.) See page 961.

Actinomyces gracilis Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato.

Actinomyces graminearum Berestnew. (Berestnew, Inaug. Diss., Moskow, 1897; see Cent. f. Bakt., I Abt., *24*, 1898, 707; *Nocardia graminarium* (sic) Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 265; *Streptothrix graminarium* Chalmers and Christopherson, *idem.*) From grain.

Actinomyces graminis Topley and Wilson. (Aktinomyces, Bostroem, Beitr. path. Anat. u. Path., *9*, 1891, 1; Topley and Wilson, Princip. Bact. and Immun., 1st ed., *1*, 1931, 250; *Actinomyces bostroemi* Baldacci, Boll. Sez. Ital. Soc. Internat. Microbiol., *9*, 1937, 141.) From bovine actinomycosis.

Actinomyces gruberi Terni. (Terni, Cent. f. Bakt., *16*, 1894, 362; *Nocardia gruberi* Blanchard, in Bouchard, Traité Path. Gén., *2*, 1896, 855; *Streptothrix grueberi* (sic) Sanfelice, Cent. f. Bakt., I Abt., Orig., *36*, 1904, 356; *Oospora gruberi*, quoted from Nannizzi, Tratt. Micopat. Umana, *4*, 1934, 51.) From soil. Produces several pigments on culture media.

Actinomyces guignardi (Sauvageau and Radais) Ford. (*Oospora guignardi* Sauvageau and Radais, Ann. Inst. Past., *6*, 1892, 255; Ford, Textb. of Bact., 1927, 220.) From dust. Gasperini (*loc. cit.*) regards this as a possible synonym of *Actinomyces chromogenus*.

Actinomyces halotrichis ZoBell and Upham. (Bull. Scripps Inst. Oceanography Univ. California, *5*, 1944, 273.) From marine mud and kelp.

Actinomyces heimi Duché. (Encyclo-

pédie Mycologique, Paris, *6*, 1934, 359.)

Actinomyces hoffmanni (Gruber) Gasperini. (*Micromyces hofmanni* (sic) Gruber, Münch. med. Wochnschr., 1891; also Arch. f. Hyg., *16*, 1893, 35; *Oospora hoffmanni* Sauvageau and Radais, Ann. Inst. Past., *6*, 1892, 252; Gasperini, Cent. f. Bakt., *15*, 1894, 684; *Streptothrix hofmanni* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 62; *Cladothrix hoffmanni* Macé, Traité Pratique de Bact., 4th ed., 1901, 1081.) Pathogenic. See page 976.

Actinomyces holmesi (Gedoelst) Nannizzi. (*Discomyces holmesi* Gedoelst, Champ. Paras. Homme et Anim., 1902; Nannizzi, Tratt. Micopat. Umana, *4*, 1934, 49.)

Actinomyces hominis Waksman. (Soil Science, *8*, 1919, 129.) Culture received from K. Meyer from Foulerton who isolated it in 1911 from an abscess of the palm. Waksman (*loc. cit.*) and Baldacci (Mycopathologia, *2*, 1940, 160) regard this as identical with Bostroem's organism (see *Actinomyces graminis* above) and Baldacci has renamed it *Actinomyces innominatus*.

Actinomyces incanescens Wollenweber. (Arb. Forschungsinst. für Kartoffelbau, 1920, 16.) From the soil of potato fields near Berlin.

Actinomyces intermedius (Krüger) Wollenweber. (*Oospora intermedia* Krüger, Berichte der Versuchsstat. f. Zuckerrohrs, Kergok-Legal, 1890; Wollenweber, Arb. d. Forschungsinst. für Kartoffelbau, 1920, 16.) From the soil of potato fields near Berlin.

Actinomyces interproximalis (Fennel) Ford. (*Streptothrix interproximalis* Fennel, Jour. Inf. Dis., *22*, 1918, 567; Ford, Textb. of Bact., 1927, 195.) From the mouth.

Actinomyces invulnerabilis (Acosta and Grande Rossi) Lachner-Sandoval. (*Cladothrix invulnerabilis* Acosta and Grande Rossi, Cronica medicoquirurgica de la Habana, No. 3, 1893; see Cent. f. Bakt., *14*, 1893, 14; *Streptothrix invulnerabilis* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 64; Lachner-Sandoval, Ueber Strahlenpilze, Strassburg, 1898; *Nocardia invulnerabilis* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 271.) From river water.

Actinomyces krausei (Chester) Ford. (*Streptothrix* aus Eiter, Krause, Münch. med. Wchnschr., *46*, 1899, 749 and Cent. f. Bakt., I Abt., *26*, 1899, 209; also see Petruschky, in Kolle and Wassermann, 2 Aufl., *5*, 1913, 267; *Streptothrix krausei* Chester, Manual Determ. Bact., 1901, 364; *Nocardia krausei* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 263; *Discomyces krausei* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 993; Ford, Textb. of Bact., 1927, 208.) From actinomycotic pus.

Actinomyces lacertae Terni. (Terni, L'Officiale Sanitario, 1896, 160; *Streptothrix lacertae* Foulerton, in Allbutt and Rolleston, Syst. of Med., *2*, 1912, 309; *Oospora lacertae* Sartory, Champ. Paras. Homme et Anim., 1923, quoted from Nannizzi, Tratt. Micopat. Umana, *4*, 1934, 51.) From grayish nodules in the liver of Italian lizards (*Lacerta viridis* and *L. agilis*).

Actinomyces lathridii (Petruschky) Ford. (*Streptothrix lathridii* Petruschky, Verhandl. d. Kong. f. innere Med., 1898; Ford, *loc. cit.*, 205.) From the beetle, *Lathridius rugicollis*.

Actinomyces loidensis Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato.

Actinomyces luteo-roseus Sanfelice. (*Actinomyces bovis luteoroseus* Gasperini, Cent. f. Bakt., *15*, 1894, 684; Sanfelice, Cent. f. Bakt., I Abt., Orig., *36*, 1904, 355.) Isolated from actinomycotic lesion in cattle.

Actinomyces marginatus Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato.

Actinomyces marinolimosus ZoBell and

Upham. (Bull. Scripps Inst. Oceanography Univ. California, *5*, 1944, 256.) From marine mud.

Actinomyces melanoroseus Roisin. (Wisti Nauk Doslid. Kat. biol. Odessa, *1*, 1929, 60.)

Actinomyces metchnikovi (Sauvageau and Radais) Ford. (*Oospora metchnikowi* Sauvageau and Radais, Ann. Inst. Past., *6*, 1892, 242; Ford, *loc. cit.*, 220.) From water. Gasperini (*loc. cit.*) regards this organism as a possible synonym of *Actinomyces chromogenus*.

Actinomyces muris ratti Lieske. (*Streptothrix ratti* Schottmüller, Dermat. Wochnschr., *58*, 1914, Supplement, 77; *Streptothrix muris-ratti* Dick and Tunnicliff, Jour. Inf. Dis., *23*, 1918, 186; Lieske, Morphol. u. Biol. d. Strahlenpilze, Leipzig, 1921, 31; regarded as identical with *Streptobacillus moniliformis* Levaditi, Nicolau and Poincloux, Compt. rend. Acad. Sci. Paris, *180*, 1925, 1188 by Topley and Wilson, Princip. of Bact. and Immun., 2nd ed., 1936, 274. The latter organism is regarded as identical with *Haverhillia multiformis* Parker and Hudson, Amer. Jour. Path., *2*, 1926, 357 by Van Rooyen, Jour. Path. and Bact., *43*, 1936, 469; *Actinomyces muris* Topley and Wilson, *loc. cit.*) From a case of rat-bite fever.

Actinomyces musculorum Hertwig. (*Actinomyces musculorum suis* Duncker, Ztschr. f. Microskopie u. Fleischbeschau, *3*, 1884, No. 3; Hertwig, Arch. f. wissensch. u. prakt. Thierheilk., *12*, 1886, 365; *Oospora musculorum suis* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 383.) Seen in calcareous deposits in the muscles of swine.

Actinomyces myricae Peklo. (Cent. f. Bakt., II Abt., *27*, 1910, 451.) From the roots of *Myrica*.

Actinomyces from Neddeni, Namyslowski. (Cent. f. Bakt., I Abt., Orig., *62*, 1912, 564.) From the human eyelid.

Actinomyces nigricans Killian and Fehér. (Ann. Inst. Past., *55*, 1935, 620.) From desert soil.

Actinomyces nigrificans (Krüger) Wollenweber. (*Oospora nigrificans* Krüger, Berichte der Versuchsstat. f. Zuckerrohrs, Kergok-Legal, 1890; Wollenweber, Arb. Forschungsinst. für Kartoffelbau, 1920, 16.) From potato scab.

Actinomyces nitrogenes Sartory, Sartory, Meyer and Walter. (Bull. Acad. Méd., Paris, *116*, 1936, 186; also Ann. Inst. Past., *58*, 1937, 684.) From sputum.

Actinomyces nivea. (Incorrectly attributed to Krainsky, 1914 by Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 270.)

Actinomyces nondiastaticus Bergey et al. (Var. b, Bergey, Jour. Bact., *4*, 1919, 304; Bergey et al., Manual, 1st ed., 1923, 371.) From air.

Actinomyces ochraceus Neukirch. (Ueber Actinomyceten, Strassburg, 1902, 4.) From soil.

Actinomyces ochroleucus Neukrich. (Ueber Actinomyceten, Strassburg, 1902, 4.) From soil.

Actinomyces odorifera Koelz. (Inaug. Diss., Kiel, 1934; Le Lait, *16*, 1936, 154.)

Actinomyces oligocarbophilus Lantzsch. (Lantzsch, Cent. f. Bakt., II Abt., *57*, 1922, 309; *Proactinomyces oligocarbophilus* Krassilnikov, Bull. Acad. Sci., U. S. S. R., No. 1, 1938, 139.) Lantzsch regards this organism as identical with *Bacillus oligocarbophilus* Beijerinck and Van Delden, Cent. f. Bakt., II Abt., *10*, 1903, 33 (*Carboxydomonas oligocarbophila* Orla-Jensen, Cent. f. Bakt., II Abt., *22*, 1909, 311). Secures growth energy by oxidizing CO to CO_2. From soil. See Manual, 5th ed., 1939, 81 for a description of the bacillary stage of this organism. *Carboxyodomonas oligocarbophila* Orla-Jensen is the type species of the genus *Carboxydomonas* Orla-Jensen (*loc. cit.*).

Actinomyces orangico-niger. (Quoted from Lieske, Morphol. u. Biol. d. Strahlenpilze, Leipzig, 1921, 33.)

Actinomyces orangicus. (Quoted from Lieske, Morphol. u. Biol. d. Strahlenpilze, Leipzig, 1921, 33.)

Actinomyces pelogenes Sawjalow.

(Cent. f. Bakt., II Abt., *39*, 1913, 440.) From mud containing hydrogen sulfide.

Actinomyces pluricolor Terni. (*Streptothrix pluricolor* Fuchs; Terni, quoted from Gasperini, Cent. f. Bakt., *15*, 1894, 684; *Nocardia pluricolor* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 268.)

Actinomyces pluricolor diffundens Berestnew. (Inaug. Diss., Moskow, 1897; see Cent. f. Bakt., I Abt., *24*, 1898, 708.) From air.

Actinomyces praecox Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato.

Actinomyces praefecundus Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato and from soil.

Actinomyces protea (Schürmayer) Ford. (*Oospora proteus* and *Streptothrix proteus* Schürmayer, Cent. f. Bakt., I Abt., *27*, 1900, 58; Ford, *loc. cit.*, 208.) From an abscess of the foot.

Actinomyces pseudotuberculosae (Flexner) Brumpt. (*Streptothrix pseudotuberculosa* Flexner, Jour. Exp. Med., *3*, 1898, 438; Brumpt, Précis de Parasit., Paris, 4th ed., 1927, 1206.)

Actinomyces pseudotuberculosus Lehmann and Neumann. (*Actinomyces atypica pseudotuberkulosa* Hamm and Keller, Cent. f. Bakt., I Abt., Ref., *42*, 1909, 729; Lehmann and Neumann, Bakt. Diag., 5 Aufl., *2*, 1912, 621; *Nocardia pseudotuberculosis* de Mello and Fernandes, Mem. Asiatic Soc. Bengal, *7*, 1919, 110.)

Actinomyces purpureus Killian and Fehér. (Ann. Inst. Past., *55*, 1935, 620.) From desert soil.

Actinomyces putorii (Dick and Tunnicliff) Ford. (*Streptothrix putorii* Dick and Tunnicliff, Jour. Inf. Dis., *23*, 1918, 183; Ford, Textb. of Bact., 1927, 216.) From the blood of a patient bitten by a weasel.

Actinomyces pyogenes Lieske. (Eine neue Streptothrixspecies, Caminiti, Cent. f. Bakt., I Abt., Orig., *44*, 1907, 193; *Streptothrix pyogenes* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 270; Lieske, Morphol. u. Biol. d. Strahlenpilze, Leipzig, 1921, 32.) From air.

Actinomyces radiatus Namyslowski. (Namyslowski, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 564; *Streptothrix radiatus* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 273; *Nocardia radiata* Vuillemin, Encyclopédie Mycologique, Paris, *2*, 1931, 126.) From an infection of the cornea of the human eye.

Actinomyces rosaceus. (Quoted from Lieske, Morphol. u. Biol. d. Strahlenpilze, Leipzig, 1921, 33.)

Actinomyces roseodiastaticus Duché. (Encyclopédie Mycologique, Paris, *6*, 1934, 329.)

Actinomyces roseus Namyslowski. (*Actinomyces sp.* Lowensteins Klin. Monatsbl. f. Augenheilk., *48*, 1910, 185; Namyslowski, Cent. f. Bakt., I Abt., Orig., *62*, 1912, 567; not *Actinomyces roseus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662; *Discomyces roseus* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 981.)

Actinomyces saharae Killian and Fehér. (Ann. Inst. Past., *55*, 1935, 621.) From desert soil.

Actinomyces salmonicolor Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From sour soil.

Actinomyces sampsonii Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato.

Actinomyces sanguinis Basu. (Ind. Jour. Med. Res., *25*, 1937, 325.) From the blood of a patient with bronchial pneumonia.

Actinomyces sanninii Ciferri. (Quoted from Baldacci, Boll. Sez. Ital. Soc. Internaz. di Microbiol., *9*, 1937, 140.)

Actinomyces setonii Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato.

Actinomyces spiralis Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From decaying grass.

Actinomyces taraxeri cepapi (Schottmüller) Ford. (*Streptothrix taraxeri*

cepapi Schottmüller, Dermat. Wchnschr., *58*, 1914, Supplement, 77; Ford, *loc. cit.*, 196.) From a case resembling rat-bite fever following the bite of a South African squirrel (*Taraxerus cepapi*).

Actinomyces tenuis Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From scab on potato.

Actinomyces thermodiastaticus Bergey et al. (Var. a, Bergey, Jour. Bact., *4*, 1919, 301; Bergey et al., Manual, 1st ed., 1923, 370.) From stomach contents of a rabbit.

Actinomyces thermotolerans Stadler. (Arch. f. Hyg., *33*, 1899, 40.) From milk and butter.

Actinomyces variabilis Cohn. (Cent. f. Bakt., I Abt., Orig., *70*, 1913, 301.) From pus in the bladder in a case of cystitis, and from the prostate.

Actinomyces verrucosus Nadson. (Nadson, Die Mikroorganismen als geologische Faktoren I. Petersburg, 1903; quoted from Dorff, Die Eisenorganismen, Pflanzenforschung, Jena, Heft 16, 1934, 43; not *Actinomyces verrucosus* Adler, 1901, see Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 46.) From sea mud. Deposits ferric hydroxide about the mycelial threads.

Actinomyces violaceus (Rossi Doria) Gasperini. (*Streptotrix violacea* Rossi Doria, Ann. d. Ist. d'Ig. sper. d. Univ. di Roma, *1*, 1891, 411; *Oospora violacea* Sauvageau and Radais, Ann. Inst. Past., *6*, 1892, 252; Gasperini, Cent. f. Bakt., *15*, 1894, 684; *Cladothrix violacea* Macé, Traité Pratique de Bact., 4th ed., 1901, 1075; *Nocardia violacea* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 270; *Discomyces violaceus* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 995.) From air and water.

Actinomyces viridis (Lombardo-Pellegrino) Sanfelice. (*Streptothrix viridis* Lombardo-Pellegrino, Riforma Med., *19*, 1903, 1065; also see Cent. f. Bakt., I Abt., Ref., *35*, 1904, 761; Sanfelice, Cent. f. Bakt., I Abt., Orig., *36*, 1904, 355.) From soil.

Actinomyces viridis Millard and Burr. (Millard and Burr, Ann. Appl. Biol., *13*, 1926, 601; not *Actinomyces viridis* Sanfelice, Cent. f. Bakt., I Abt., Orig., *36*, 1904, 355; not *Actinomyces viridis* Duché, Encyclopédie Mycologique, Paris, *6*, 1934, 311.) From scab on potato.

Actinomyces xanthostromus Wollenweber. (Arb. Forschungsinst. f. Kartoffelbau, 1920, 16.)

Actinomyces wedmorensis Millard and Burr. (Ann. Appl. Biol., *13*, 1926, 601.) From peat soil.

Asteroides lieskeyi Puntoni and Leonardi. (Boll. e Atti d. R. Accad. Med. di Roma, *61*, 1935, 94.) A renaming of *Actinomyces lieskey*, a culture whose source was unknown. This may possibly be the same as *Actinomyces lieskei* Duché (see *Streptomyces lieskei*).

Cladothrix odorifera Rullmann. (Rullmann, Inaug. Diss., Munich, 1895; see Cent. f. Bakt., I Abt., *17*, 1895, 884 and Cent. f. Bakt., II Abt., *2*, 1896, 116; *Oospora odorifera* Lehmann and Neumann, Bakt. Diag., 1 Aufl., *2*, 1896, 392; *Actinomyces odorifer* Lachner-Sandoval, Ueber Strahlenpilze, 1898, 65; *Streptothrix odorifera* Foulerton and Jones, Trans. Path. Soc. London, *53*, 1902, 112; *Nocardia odorifera* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 818.) From sputum in a case of chronic bronchitis.

Cladothrix placoides Kligler. (*Leptothrix placoides alba* Dobrzyniecki, Cent. f. Bakt., I Abt., *21*, 1897, 225; Kligler, Jour. Allied Dental Soc., *10*, 1915, 141, 282 and 445; *Leptotrichia placoides* Bergey et al., Manual, 3rd ed., 1930, 458.) From a tooth canal. For a description of this species see Manual, 5th ed., 1939, 829. The description indicates that this organism belongs to *Nocardia* or *Streptomyces*.

Coccobacillus pseudo - actinomycosis polymorphus Berestneff. (Berestneff, 1898, quoted from Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 273.)

Cohnistreptothrix americana Chalmers and Christopherson. (*Streptothrix sp.*

Bloomfield and Bayne-Jones, Johns Hopkins Hosp. Bull. 26, 1915, 230; Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 273; *Actinomyces americanus* Dodge, Medical Mycology, St. Louis, 1935, 716.) From a liver abscess.

Cohnistreptothrix misri Carpano. (Riv. di Parasit., No. 2, 1937, 107.) From human dermatosis in Egypt.

Cohnistreptothrix silberschmidtii Chalmers and Christopherson. (Streptothrix, Silberschmidt, Cent. f. Bakt., I Abt., *27*, 1900, 486; Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 273; *Nocardia silberschmidti* Froilano de Mello and Fernandes, Mem. Asiatic Soc. Bengal, *7*, 1919, 111; *Actinomyces silberschmidti* Dodge, Medical Mycology, St. Louis, 1935, 711.) From cases of dacryocystitis.

Discomyces decussatus Langeron and Chevallier. (Langeron and Chevallier, Compt. rend. Soc. Biol., *72*, 1912, 1030; *Nocardia decussata* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 817; *Oospora decussata* Sartory, Champ. Paras. Homme et Anim., 1923, 825; *Actinomyces decussatus* Brumpt, Précis de Parasitol., 4th ed., 1927, 1206.) From dry, scaly lesions. Not considered pathogenic.

Nocardia chalmersi de Mello and Fernandes. (De Mello and Fernandes, Mem. Asiatic Soc. Bengal, *7*, 1919, 130; *Actinomyces chalmersi* Dodge, Medical Mycology, St. Louis, 1935, 734.) From the saliva of a horse.

Nocardia christophersoni de Mello and Fernandes. (De Mello and Fernandes, Mem. Asiatic Soc. Bengal, *7*, 1919, 130; *Actinomyces christophersoni* Dodge, Medical Mycology, St. Louis, 1935, 723.) From the air.

Nocardia citrea Chalmers and Christopherson. (Ann. Trop. Med. and Parasit., *10*, 1916, 270.) A blanket name proposed to include *Actinomyces griseoflavus* Krainsky, *Actinomyces flavus* Krainsky, *Streptothrix flava* Sanfelice and *Streptothrix flava* Bruns.

Nocardia cruoris Macfie and Ingram. (Macfie and Ingram, Ann. Trop. Med. and Parasit., *15*, 1921, 283; *Discomyces cruoris* Brumpt, Précis de Parasitol., Paris, 3rd ed., 1922, 984; *Oospora cruoris* Sartory, Champ. Paras. Homme et Anim., 1923, 809; *Actinomyces cruoris* Brumpt, *ibid.*, 4th ed., 1927, 1195.) From blood.

Nocardia dichotoma (Macé) Chalmers and Christopherson. (*Cladothrix dichotoma* Macé, Compt. rend. Acad. Sci. Paris, *6*, 1888, 1622; not *Cladothrix dichotoma* Cohn, Beitr. z. Biol. d. Pflanzen *1*, Heft 3, 1875, 185; Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 270.)

Nocardia ferruginea Trevisan. (Bakterium bei Chorea St. Viti, Naunyn, Mittheil. aus der Med. Klinik zu Königsberg, 1888, 292; Trevisan, I generi e le specie delle Batteriacee, 1889, 9; *Actinomyces ferrugineus* Gasperini, Cent. f. Bakt., *15*, 1894, 684.) From pia mater in a case of St. Vitis' dance.

Nocardia garteni (Brumpt) Castellani and Chalmers. (*Cladothrix liquefaciens No. 2*, Garten, Deutsche Ztschr. f. Chirurg., *41*, 1895, 482; *Discomyces garteni* Brumpt, Précis de Parasitol., Paris, 1st ed., 1910, 860; Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 818; *Oospora garteni* Sartory, Champ. Paras. Homme et Anim., 1923, 778; *Actinomyces garteni* Brumpt, *loc. cit.*, 4th ed., 1927, 1191; *Actinomyces liquefaciens* Ford, Textb. of Bact., 1927, 202.) From cases of human actinomycosis.

Nocardia goensis de Mello and Fernandes. (De Mello and Fernandes, Mem. Asiatic Soc. Bengal, *7*, 1919, 130; *Actinomyces goensis* Dodge, Medical Mycology, St. Louis, 1935, 723.) From lesions of vitiligo. Saprophytic.

Nocardia liguire Urizer. (Urizer, 1904; *Actinomyces liguire* Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 49.)

Nocardia liquefaciens (Hesse) Castel-

lani and Chalmers. (*Cladothrix liquefaciens* Hesse, Deutsche Ztschr. f. Chirurg., *41*, 1895, 432; *Discomyces liquefaciens* Brumpt, Précis de Parasit., Paris, 1st ed., 1910, 860; Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 818; *Streptothrix liquefaciens* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 233, 265; *Oospora liquefaciens* Sartory, Champ. Paras. Homme et Anim., 1923, 778; *Actinomyces liquefaciens* Brumpt, *loc. cit.*, 4th ed., 1927, 1192.) From an inguinal abscess.

Nocardia microparva Chalmers and Christopherson. (Ann. Trop. Med. and Parasit., *10*, 1916, 268.) Listed as synonymous with *Actinomyces microparva* Krainsky, 1914 which may be intended for *Actinomyces microflavus* Krainsky, Cent. f. Bakt., II Abt., *41*, 1914, 662.

Nocardia orangica (Berestneff) Chalmers and Christopherson. (*Streptothrix orangica* Berestneff, Inaug. Diss., Moscow, 1897, quoted from Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 271; Chalmers and Christopherson, *idem.*)

Nocardia rogersi de Mello. (*Nocardia* (*Cohnistreptothrix*) *rogersi* de Mello, A Med. Contemp., 1919; *Discomyces rogersi* Neveu-Lemaire, Précis Parasitol. Hum., 5th ed., 1921, 44; *Actinomyces rogersii* Brumpt, Précis de Parasitol., 4th ed., 1927, 1206.) From sputum.

Nocardia rubea Chalmers and Christopherson. (Ann. Trop. Med. and Parasit., *10*, 1916, 271.) *Nomen nudum.* According to Dodge (Medical Mycology, St. Louis, 1935, 765), this is a synonym of *Oospora rubra* Wilbert, Recueil Hyg. Méd. Vét. Militaire, 1908.

Nocardia saprophytica Chalmers and Christopherson. (*Streptothrix leucea saprophytica* Foulerton, 1902, quoted from Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 270; Chalmers and Christopherson, *idem.*)

Nocardia urinaria Pijper. (Pijper, 1918, quoted from Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 1057; *Actinomyces urinarius* Nannizzi, in Pollacci, Tratt. Micopat. Umana, *4*, 1934, 50.)

Oospora hoffmanni (Gruber) Sauvageau and Radais. (*Mikromyces hofmanni* (sic) Gruber, Trans. Int. Congr. Hyg. Derm., VI, *2*, 1891–1892, 65 and Arch. f. Hyg., *16*, 1893, 35; Sauvageau and Radais, Ann. Inst. Past., *6*, 1892, 251; *Actinomyces hoffmanni* Gasperini, Cent. f. Bakt., *15*, 1894, 684; *Streptothrix hofmanni* Kruse, in Flügge, Die Mikroorganismen, 3 Aufl., *2*, 1896, 62; *Cladothrix hoffmanni* Macé, Traité Pratique de Bact., 4th ed., 1901, 1081; *Nocardia hoffmanni* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 268.) From a sample of vaccine.

Oospora spumalis Sartory. (Sartory, in Sartory and Bailly, Mycoses pulmonaires, 1923, 318; *Actinomyces spumalis* Dodge, Medical Mycology, St. Louis, 1935, 751.) From human sputum.

Streptothrix aaser Johan-Olsen. (Inaug. Diss., Christiania, 1893, 91; quoted from Neukirch, Ueber Actinomyceten, Strassburg, 1902, 69.)

Streptothrix alpha Price-Jones. (Price-Jones, 1900; quoted from Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 270.) Considered synonymous with *Streptothrix alba* (Rossi Doria).

Streptothrix aquatilis Johan-Olsen. (Inaug. Diss., 1893, 93; quoted from Johan-Olsen, Cent. f. Bakt., II Abt., *3*, 1897, 279.)

Streptothrix beta Price-Jones. (Price-Jones, 1900; quoted from Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 270; *Nocardia beta* Chalmers and Christopherson, *idem.*)

Streptothrix chondri Johan-Olsen. (Inaug. Diss., 1893, 95; quoted from Johan-Olsen, Cent. f. Bakt., II Abt., *3*, 1897, 278.)

Streptothrix enteritidis Pottien. (Quoted from Sanfelice, Cent. f. Bakt., I Abt., Orig., *36*, 1904, 355.)

Streptothrix foersteri Gasperini. (Gasperini, Annales de Micrographie, *2*, 1890, 462; not *Streptothrix foersteri* Cohn, Beitr. z. Biol. d. Pflanzen, *1*, Heft 3, 1875, 196; *Actinomyces saprophyticus* Gasperini, Ann. d. Ist. d'Ig. sper. d. Univ. Roma, *2*, 1892, 226; *Actinomyces saprophyticus* var. *cromogenus* Gasperini, *ibid.*, 229.) From air.

Streptothrix gelatinosus Johan-Olsen. (Cent. f. Bakt., II Abt., *3*, 1897, 279.)

Streptothrix humifica Johan - Olsen. (Cent. f. Bakt., II Abt., *3*, 1897, 278.)

Streptothrix lemani Johan-Olsen. (Inaug. Diss., 1893, 96; quoted from Johan-Olsen, Cent. f. Bakt., II Abt., *3*, 1897, 279.)

Streptothrix necrophora Wilhelm. (Monats. f. prakt. Tierheilk., *14*, 1902, 193.) See page 578.

Streptothrix leucea Foulerton. (In Allbutt and Rolleston, Syst. of Med., *2*, 1912, 310.)

Streptothrix melanotica Price-Jones. (On the General Characteristics and Pathogenic Action of the Genus *Streptothrix*, 1901; also see Foulerton, in Allbutt and Rolleston, Syst. of Med., *2*, 1912, 304.)

Streptothrix oidieformis Johan-Olsen. (Inaug. Diss., 1893, 96; quoted from Neukirch, Ueber Actinomyceten, Strassburg, 1902, 69.)

Streptothrix spirilloides Johan-Olsen. (Inaug. Diss., 1893, 96; quoted from Neukirch, Ueber Actinomyceten, Strassburg, 1902, 69.)

Streptothrix tartari Sanfelice. (Cent. f. Bakt., I Abt., Orig., *36*, 1904, 355.)

Streptothrix wallemia Johan-Olsen. (Inaug. Diss., 1893, 96; quoted from Neukirch, Ueber Actinomyceten, Strassburg, 1902, 69.)

Streptothrix zopfi Casagrandi. (Quoted from Caminiti, Cent. f. Bakt., I Abt., Orig., *44*, 1907, 198.)

Drechsler (Botan. Gazette, *67*, 1919, 65 and 147) described eighteen morphological types of *Actinomyces* (*Streptomyces*). The relationships of these types to species previously described in the literature are not explained except in four instances. Actinomyces III is regarded as *Actinomyces lavendulae* Waksman and Curtis; Actinomyces X is regarded as *Streptothrix alba* Rossi Doria (possibly *Actinomyces griseus* Krainsky); Actinomyces XII is regarded as *Actinomyces aureus* Waksman and Curtis; and Actinomyces XVII is *Actinomyces scabies* Güssow.

Genus II. Micromonospora *Ørskov.*

(Ørskov, Investigations into the morphology of the ray fungi. Copenhagen, 1923, 147; includes *Thermoactinomyces* Tsilinsky, Ann. Inst. Past., *13*, 1899, 501; *ibid.*, *17*, 1903, 206.)

Well developed, fine, non-septate mycelium, 0.3 to 0.6 micron in diameter. Grow well into the substrate. Not forming at any time a true aerial mycelium. Multiply by means of conidia, produced singly at end of special conidiophores, on surface of substrate mycelium. Conidiophores short and either simple, branched or produced in clusters. Strongly proteolytic and diastatic. Many are thermophilic and can grow at 65°C. Usually saprophytes. These organisms occur mostly in hot composted manure, dust, soil and in lake bottoms.

The type species is *Micromonospora chalcea* (Foulerton) Ørskov.

Key to the species of genus Micromonospora (*Ørskov Group III*).

I. Vigorously growing organisms, typically with copious spore formation on glucose-asparagine-agar.
   A. Vegetative mycelium pale pink to deep orange, no typical soluble pigment.
      1. *Micromonospora chalcea.*
   B. Vegetative mycelium orange changing to brownish-black, brown soluble pigment.
      2. *Micromonospora fusca.*

II. Slowly and feebly growing organisms, with scant spore formation on glucose-asparagine-agar, no soluble pigment.
   A. Vegetative mycelium pale pink to pale orange.
      3. *Micromonospora parva.*
   B. Vegetative mycelium yellow to orange-red.
      4. *Micromonospora globosa.*
   C. Vegetative mycelium blue.
      5. *Micromonospora vulgaris.*

NOTE: This genus could be subdivided on the basis of the relations of the organisms to temperature, since it includes a number of thermophilic forms which grow readily at 55° to 65°C, mesophilic forms having their optimum temperature at 30°C, and organisms growing at low temperatures in lakes. Each of these can be divided into 3 groups, based on the structure of the spore-bearing hyphae. Among the thermophilic forms, only representatives of the first group have so far been isolated in pure culture although the existence of the other two groups has definitely been demonstrated in microscopic preparations. These are:

Group 1. Simple spore-bearing hyphae.
Group 2. Branching spore-bearing hyphae.
Group 3. Spore-bearing hyphae in clusters.

1. **Micromonospora chalcea** (Foulerton) Ørskov. (*Streptothrix chalcea* Foulerton, Lancet, *1*, 1905, 1200; *Nocardia chalcea* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 268; Ørskov, Thesis, Copenhagen, 1923, 156; *Actinomyces chalcea* Ford, Textb. of Bact., 1927, 221.) From Greek *chalceus*, bronze.

Description from Jensen, Proc. Linn. Soc. New So. Wales, *57*, 1932, 173.

Formation of a unicellular mycelium which forms distally placed, singly situated spores. No aerial hyphae. No sur-

face growth in liquid medium. The organism resists desiccation for at least 8 months. Comparison between the power of resistance of the mycelium and the spores, respectively, will no doubt present great difficulty, because it is almost impossible to ensure that the two constituents are actually detached. Otherwise, the mycelium is but slightly capable of germinating, which may be ascertained by inoculating a water agar plate liberally with a mixture of mycelial threads and spores. While practically all the spores germinate, the mycelial threads were never found to form new colonies.

Vegetative mycelium on glucose-asparagine-agar: Heavy, compact, raised, pale pink to deep orange, not spreading much into the medium. Spore-layer well developed, moist and glistening, brownish-black to greenish-black, this color sometimes spreading through the whole mass of growth.

Gelatin is liquefied.

Grows in liquid media as small firm orange granules or flakes.

Milk is digested with a faintly acid reaction, mostly after a previous coagulation.

Many strains invert sucrose.

Some strains produce nitrites from nitrates.

Starch is hydrolyzed.

Most strains decompose cellulose.

Proteolytic action seems stronger in this than in the other species of this genus.

Optimum temperature for growth 30° to 35°C. Thermal death point of mycelium, 70°C in 2 to 5 minutes. Spores resist 80°C for 1 to 5 minutes.

Habitat: Soil, lake mud and other substrates. In addition to the above references, see Erikson (Jour. Bact., *41*, 1941, 299) and Umbreit and McCoy (A Symposium on Hydrobiology, Univ. of Wisconsin Press, 1941, 106–114).

2. **Micromonospora fusca** Jensen. (Proc. Linn. Soc. New So. Wales, *57*, 1932, 178.) From Latin *fuscus*, dark.

Vegetative mycelium on glucose-asparagine-agar heavy, compact, orange, rapidly changing to deep brown and nearly black; spore-layer moist, glistening, grayish- to brownish-black. Deep brown soluble pigment.

Gelatin is liquefied.

Grows in liquid media as small brown granules and flakes.

Milk is slowly digested; no coagulation.

Sucrose is inverted.

Reduction of nitrates, positive or negative.

Cellulose is attacked to a slight extent.

Starch is hydrolyzed.

Habitat: Soil.

3. **Micromonospora parva** Jensen. (Proc. Linn. Soc. New So. Wales, *57*, 1932, 177.) From Latin *parvus*, small.

Scant growth on glucose-asparagine-agar; vegetative mycelium thin, spreading widely into the agar, almost colorless to pale pink or orange. Sporulation scant, giving rise to thin grayish, moist crusts on the surface.

Gelatin is liquefied.

Milk is left unchanged; or coagulated, slowly redissolved with faintly acid reaction.

Sucrose not inverted.

Nitrates not reduced.

Cellulose not decomposed.

Starch is hydrolyzed.

Habitat: Soil.

4. **Micromonospora globosa** Krassilnikov. (Ray Fungi and Related Organisms. Izd. Acad. Nauk, Moskow, 1938, 134; Microbiology, U. S. S. R., *8*, 1939, 179.) From Latin *globosus*, spherical.

A fine (0.5 to 0.8 micron in diameter) monopodially branching mycelium. This mycelium breaks soon into separate pieces of varying length and irregular outline. Conidia are formed at the ends of short branches, one on each. Individual branches with conidia resemble grape vines. The conidia are spherical, 1.0 to 1.3 microns; they arise by the

swelling of the branch tips. The swellings become round, acquire the shape of spheres, which, as the formation of the conidia proceeds, are divided from the branch by a transverse septum.

Gelatin is liquefied.

Colonies: Rugose, at first very compact, later acquire a pasty consistency, and their bond with the medium becomes not so fast. The color of the cultures varies from light yellow to orange-red. During fruit-bearing the colonies are covered with a brownish-black tarnish of conidia.

In meat-peptone broth, ammonia is produced.

Milk: Coagulation; peptonization.

Nitrites are produced from nitrates.

Sucrose is inverted.

Cellulose not decomposed.

Starch is hydrolyzed.

Habitat: Soil.

5. **Micromonospora vulgaris** (Tsilinsky) Waksman, Umbreit and Gordon. (Thermophile *Cladothrix*, Kedzior, Arch. Hyg., *27*, 1896, 328; *Thermoactinomyces vulgaris* Tsilinsky, Ann. Inst. Past., *13*, 1899, 501; *Actinomyces monosporus* Schütze, Arch. f. Hyg., *67*, 1908, 50 (*Nocardia monospora* Chalmers and Christopherson, Ann. Trop. Med. and Parasit., *10*, 1916, 271); *Actinomyces glaucus* Lehmann and Schütze, in Lehmann and Neumann, Bakt. Diag., 5 Aufl., *2*, 1912, 641 (*Nocardia glauca* Chalmers and Christopherson, *loc. cit.*); *Micromonospora coerulea* Jensen, Proc. Linn. Soc. New So. Wales, *57*, 1932, 177; Waksman, Umbreit and Gordon, Soil Sci., *47*, 1939, 51.) From Latin *vulgaris*, common.

Morphologically the development of this organism is entirely comparable to that of the mesophilic form described by Jensen. The young mycelium shows slightly more branching than that produced by species of *Streptomyces*. Spores are borne at the end of short branches from which they are easily broken. The aerial mycelium, though present, is usually rudimentary, rarely exhibiting the tangled network of strands typical of species of *Streptomyces*. Thermophilic strains of *Micromonospora vulgaris* differ thus from the mesophilic forms, which show no trace of aerial mycelium. Fragmentation has not been seen in slide cultures of the organism thus far isolated, but it was found to occur in smear preparation.

According to Jensen, the mesophilic strains grow slowly on glucose-asparagine-agar; vegetative mycelium dense, dark greenish-blue, with a hard and glossy surface. Sporulation very scant. The surface sometimes shows a thin white veil resembling aerial mycelium, but without aerial spores.

Gelatin: Liquefaction.

Good growth on beef-peptone agar, potato, milk, beef-peptone broth, etc. Grows in liquid media as fairly large, firm, round, white to pink granules (Jensen). Usually a white, powdery, thin aerial mycelium is produced which is hardly raised above the surface. No soluble pigment is formed.

Czapek's agar: Growth white, powdery, slightly raised.

Broth: A tough white pellicle and in many instances a considerable number of ball-like colonies at the bottom of the tube. No turbidity.

Milk: Coagulated and digested.

Nitrites not produced from nitrates.

Sucrose not inverted.

Cellulose not decomposed.

Starch is hydrolyzed.

Optimum temperature of thermophilic forms 57°C. Growth range 48° to 68°C.

Habitat: Straw, soil, high temperature composts.

Appendix: The following anaerobic species has been described:

Micromonospora propionici Hungate. (Abst. in Jour. Bact., *48*, 1944, 380 and 499; Jour. Bact., *51*, 1946, 51.) From the alimentary tract of the wood-eating termite (*Amitermes minimus*). Ferments glucose or cellulose to form acetic and propionic acids and CO_2. Obligate anaerobe.

ORDER III. CHLAMYDOBACTERIALES BUCHANAN.

(Jour. Bact., *2*, 1917, 162.)

Filamentous, colorless, alga-like bacteria. May or may not be ensheathed. They may be unbranched or may show false branching. False branching arises from a lateral displacement of the cells of the filament within the sheath which gives rise to a new filament, so that the sheath is branched while the filaments are separate. The sheath may be composed entirely of iron hydroxide, or of an organic matrix impregnated with iron, or may be entirely organic. The filaments themselves may show motility by a gliding movement like that found in the blue-green algae (*Oscillatoriaceae*). Conidia and motile flagellate swarm cells may be developed, but never endospores. Fresh water and marine forms.

Key to the families of order **Chlamydobacteriales.***

I. Alga-like filaments which do not contain sulfur globules. False branching may occur.
   A. Usually free floating filaments. Motile swarm cells may be formed.
      Family I. *Chlamydobacteriaceae*, p. 981.
   B. Attached filaments which show a differentiation of base and tip. Non-motile conidia formed in the swollen tips of the filaments.
      Family II. *Crenothrichaceae*, p. 987.

II. Alga-like, unbranching filaments which may contain sulfur globules when growing in the presence of sulfides. Filaments may be motile by a creeping or sliding movement along a solid substrate.
      Family III. *Beggiatoaceae*, p. 988.

FAMILY I. CHLAMYDOBACTERIACEAE MIGULA.**

(Arb. Bakt. Inst. Hochschule, Karlsruhe, *1*, 1894, 237.)

Filamentous bacteria which frequently show false branching. Sheaths may or may not be impregnated with ferric hydroxide. Cells divide only transversely. Swarm cells, it developed, are usually motile by means of flagella. Usually found in fresh water.

Key to the genera of family **Chlamydobacteriaceae.**

I. Showing typical false branching.
   A. Sheaths entirely organic, not impregnated with ferric hydroxide.
      Genus I. *Sphaerotilus*, p. 982.
   B. Sheaths impregnated with ferric hydroxide.
      Genus II. *Clonothrix*, p. 983.

II. Unbranched or rarely showing false branching.
   A. Sheaths or holdfasts impregnated with ferric hydroxide.
      Genus III. *Leptothrix*, p. 983.

---

* In Appendix I, p. 996, will be found a group of non-filamentous, non-sheath-forming, colorless sulfur bacteria, as the family *Achromatiaceae*. Their true relationships are as yet obscure, and they have been attached as an Appendix to the *Chlamydobacteriales* largely on account of the similarity of their metabolism to that of the *Beggiatoaceae*.

** Completely revised by Prof. A. T. Henrici, University of Minnesota, Minneapolis, Minnesota, December, 1938; further revision by Prof. Robert S. Breed, New York State Experiment Station, Geneva, New York, July, 1946.

Genus I. Sphaerotilus *Kützing.*

(Kützing, Linnaea, *8*, 1833, 385; *Cladothrix* Cohn, Beitr. z. Biol. d. Pflanz., *1*, Heft 3, 1875, 185.) From Greek *sphaera*, sphere.

Attached, colorless threads, showing false branching, though this may be rare in some species. Filaments consist of rod-shaped or ellipsoidal cells, surrounded by a firm sheath. Multiplication occurs both by non-motile conidia and by motile swarm cells, the latter with lophotrichous flagella.

The type species is *Sphaerotilus natans* Kützing.

1. **Sphaerotilus natans** Kützing. (Kützing, Linnaea, *8*, 1833, 385; not *Sphaerotilus natans* Sack, Cent. f. Bakt., II Abt., *65*, 1925, 116; *Cladothrix natans* Migula, in Engler and Prantl, Die natürl. Pflanzenfam. *1*, 1a, 1895, 46.) From Latin *natans*, swimming.

Cells cylindrical, surrounded by a sheath which is slimy in character, 2 to 3 microns in diameter. False branching rare.

Multiplication occurs through the formation of conidia within the sheath of the vegetative cells, from which they swarm out at one end, swim about for a time, then attach themselves to objects and develop into delicate filaments.

Gelatin rapidly liquefied, requires organic nitrogen, does not grow in the ordinary peptone solution, grows best with low concentrations of meat extract (Zikes, Cent. f. Bakt., II Abt., *43*, 1915, 529).

The culture cultivated and described as *Sphaerotilus natans* by Sack (Cent. f. Bakt., II Abt., *65*, 1925, 116) was identified as *Bacillus mycoides* by Haag (*ibid.*, *69*, 1926, 4).

Source: Originally found in polluted waters. May become a real nuisance in sewage purification plants of the activated sludge type (Lackey and Wattie, U. S. Pub. Health Ser., Pub. Health Repts., *55*, 1940, 975) and in streams polluted with sulfite liquor from pulp and paper mills (Lackey, Mimeographed Rept. U. S. Pub. Health Ser., 1941).

Habitat: Stagnant and running water, especially sewage polluted streams.

2. **Sphaerotilus dichotomus** (Cohn) Migula. (*Cladothrix dichotoma* Cohn, Beitr. z. Biol. d. Pflanz., *1*, Heft 3, 1875, 185; Migula, Syst. d. Bakt., *2*, 1900, 1033; *Sphaerotilus natans* var. *cladothrix* Butcher, Trans. Brit. Myc. Soc., *17*, 1932, 112.) From Greek *dichotomos*, cut in two parts, forked.

The identity of this species as distinct from *Sphaerotilus natans* has been questioned. Cohn's description applied to filaments 0.3 micron in diameter, while all later authors have applied the name to a much larger organism (2 to 4 microns in diameter).

Zikes (Cent. f. Bakt., II Abt., *43*, 1915, 529) gives the following differential characters: Cells smaller than *Sphaerotilus natans*, 1.5 to 2.5 microns; false branching constant; grows best in high concentrations of meat extract; will grow in ordinary peptone solutions; can utilize inorganic nitrogen; liquefies gelatin slowly.

Source: Found by Cohn in water containing *Myconostoc*.

Habitat: Comparatively unpolluted fresh water capable of sustaining algae.

3. **Sphaerotilus fluitans** (Migula) Schikora. (*Streptothrix fluitans* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., *1*, 1a, 1895, 38; Schikora, Ztschr. f. Fischerei, *7*, 1899, 1-28; *Chlamydothrix fluitans* Migula, Syst. d. Bakt., *2*, 1900, 1033; *Leptothrix fluitans* Chester, Man. Determ. Bact., 1901, 370.) From Latin *fluitans*, flowing, floating.

Very thin attached filaments surrounded by a soft sheath, from which almost spherical conidia issue, usually attaching themselves to the exterior of the sheath, where they multiply.

Habitat: Swamp water or sewage polluted waters.

Appendix: Additional species have been described as belonging in this genus. Those described by Ravenel have generally been overlooked although he was one of the earliest workers to culture these organisms. The list follows:

Cladothrix fungiformis Ravenel. (Mem. Nat. Acad. Sci., *8*, 1896, 19.) From deep virgin soil.

Cladothrix intestinalis Ravenel (*loc. cit.*, 18). From virgin soil.

Cladothrix non-liquefaciens Ravenel (*loc. cit.*, 16). From deep made soil.

Cladothrix profundus Ravenel (*loc. cit.*, 17). From deep made soil.

Cladothrix ramosa Gasperini. (Atti d. Soc. toscana d'Ig., *2*, 1912, 000.) From water.

Cladothrix reticularis Naumann. (Kungl. Svenska Vetenskapsakad. Handl., I, *62*, Part 4, 1921, 44; *Sphaerotilus reticularis* Cataldi, Thesis, Univ. Buenos Aires, 1939, 55.) From Aneboda region, Sweden.

Sphaerotilus roseus Zopf. (Beiträge z. Physiol. u. Morph. nieder. Organismen, 1892, 32.) From water.

Genus II. **Clonothrix** *Roze.*

(Jour. d. Bot., *10*, 1896, 325.) From Greek *klon*, a twig and *thrix*, hair.

Attached filaments showing false branching as in *Sphaerotilus*. Sheaths organic, encrusted with iron or manganese, broader at the base and tapering toward the tip. Cells colorless, cylindrical. Reproduction by spherical conidia formed in chains by transverse fission of cells; conidia formation acropetal, limited to short branches of the younger portion of the filaments.

The type species is *Clonothrix fusca* Roze.

1. **Clonothrix fusca** Roze. (Roze, Jour. d. Bot., *10*, 1896, 325; *Clonothrix fusca* Schorler, Cent. f. Bakt., II Abt., *12*, 1904, 689; *Crenothrix fusca* Dorff, Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 41.) From Latin *fuscus*, brown.

Cells cylindrical with rounded ends, 2 by 10 microns, becoming larger toward the base and smaller toward the tips of the filaments.

Sheaths 7 microns at the base to 2 microns at the tips.

Conidia about 2 microns in diameter.

This organism was described by Roze as a blue-green alga, but subsequent observers have failed to find pigment. It was described independently by Schorler who gave it the same name. Cholodny considered it identical with *Crenothrix polyspora* but Kolk (Amer. Jour. Bot., *25*, 1938, 11) has clearly differentiated these species.

Habitat: Waterworks and pipes.

Appendix: Apparently the following species resemble *Clonothrix fusca*:

Clonothrix tenuis Kolkwitz. (Kolkwitz, Schizomycetes in Kryptogamenflora der Mark Brandenburg, *5*, 1915, 144; *Crenothrix tenuis* Dorff, Die Eisenorganismen, Pflanzenforschung, Heft *16*, 1934, 42.) From the settling basin of a sewage plant near Berlin. Dorff thinks this may have been a growth form of *Crenothrix fusca* Dorff.

Mycothrix abundans Naumann. (Kungl. Svenska Vetenskapsakad. Handl. I, *62*, 1921, Part 4, 44.) From the Aneboda region, Sweden. The type species of the genus *Mycothrix.*

Mycothrix clonotricoides Naumann (*loc. cit.*, 54). From the Aneboda region, Sweden.

Genus III. **Leptothrix** *Kützing.*

(Kützing, Phycologia Generalis, 1843, 198; not *Leptotrichia* Trevisan, Reale Ist. Lombardo di Sci. e Lettere, Ser. 2, *12*, 1879, 138; *Detoniella* DeToni and Trevisan, in

Saccardo, Sylloge Fungorum, *6*, 1889, 929; *Chlamydothrix* Migula, Syst. d. Bakt., *2*, 1900, 1030; *Conidiothrix* Benecke, Bau u. Leben d. Bakt., 1912, 489; *Megalothrix* Schwers, Cent. f. Bakt., II Abt., *33*, 1912, 273; *Syncrotis* Enderlein, Sitzber. Gesell. Naturf. Freunde, Berlin, 1917, 312.) From Greek *leptos*, small and *thrix*, hair.

Filaments of cylindrical colorless cells, with a sheath at first thin and colorless, later thicker, yellow or brown, encrusted with ferric hydroxide. The oxide may be dissolved by dilute acid, whereupon the inner cells show up well. Multiplication is by division and abstraction of cells and by motile cylindrical swarmers. False branching may occur.

The type species is *Leptothrix ochracea* Kützing.

Key to the species of genus **Leptothrix.**

I. Filaments not spirally twisted.
  A. Free swimming, not attached.
    1. Sheath homogeneous, cylindrical.
      1. *Leptothrix ochracea.*
    2. Sheath composed of a bundle of fine parallel filaments.
      2. *Leptothrix trichogenes.*
  B. Attached to a substrate by a holdfast.
    1. Arising singly, each filament from its own holdfast.
      a. Filaments show false branching.
        3. *Leptothrix discophora.*
      aa. Filaments unbranched.
        4. *Leptothrix sideropous.*
    2. Numerous filaments arising from a common holdfast.
      a. Filaments large, uniform in diameter.
        5. *Leptothrix lopholea.*
      aa. Filaments smaller, tapering toward the tip.
        6. *Leptothrix echinata.*
II. Filaments spirally twisted.
  A. Epiphytic, growing twisted around filamentous algae.
    7. *Leptothrix epiphytica.*
  B. Not epiphytic.
    8. *Leptothrix pseudovacuolata.*

1. **Leptothrix ochracea** Kützing. (Kützing, Phycologia Generalis, 1843, 198; *Lyngbya ochracea* Thuret, Ann. Sci. Nat. Bot., VI, *1*, 1875, 279; *Beggiatoa ochracea* Gasperini, Ann. d'Igiene Sper., *2*, 1912, 000; *Chlamydothrix ochracea* Migula, Syst. d. Bakt., *2*, 1900, 1031.) From Latin *ochra*, yellow.

Long filaments, free-floating, never attached to a substrate, never branching. Filaments 1 micron in thickness, composed of rod-like colorless cells, surrounded in young filaments by a delicate sheath which later becomes yellow to brown in color.

Sheath homogeneous, completely dissolving in dilute hydrochloric acid.

When the sheath becomes very thick, the filaments creep out of the sheath and secrete a new one, so that many empty sheaths are found. Polar flagellate, motile, swarm-cells have been observed.

Habitat: Iron-bearing waters.

2. **Leptothrix trichogenes** Cholodny. (Cholodny, Cent. f. Bakt., II Abt., *61*, 1924, 292; *Toxothrix ferruginea* Molisch, Die Eisenbakterien in Japan, Sc. Report Tohoku J. Univ., 4 Ser. Biol., *1*, 1925,

13.) From Greek *thrix*, hair and *geno*, producing.

Long, slender, articulated filaments, free-floating, never branched. Filaments 0.5 micron in thickness, composed of rod-like colorless cells.

Filaments surrounded by a fine sheath. This sheath ruptures longitudinally and rolls up as a fine hair-like body at one side of the filament. This process continually repeated leads to the development of a thick sheath composed of numerous hair-like bodies arranged in parallel bundles, which are easily separated from the filament. The sheath is completely dissolved in dilute hydrochloric acid.

Mode of reproduction is unknown.

Habitat: Iron-bearing waters.

3. **Leptothrix discophora** (Schwers) Dorff. (*Megalothrix discophora* Schwers, Cent. f. Bakt., II Abt., *33*, 1912, 273; *Leptothrix crassa* Cholodny, Cent. f. Bakt., II Abt., *61*, 1924, 292; *Chlamydothrix discophora* Naumann, Ber. d. Deutsch. Bot. Ges., *46*, 1928, 141; Dorff, Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 31.) From Latin *discus*, disk and Greek *phorous*, to bear.

Long, slender, articulated filaments composed of elements of varying length showing false branching (Cholodny, *loc. cit.*, 297). Usually attached to a submerged substrate but may be free-floating.

Filaments surrounded by a heavy sheath, thick (10 to 15 microns) at the base, tapering toward the free tip, heavily impregnated with ferric hydroxide.

Reproduction by motile swarm cells liberated from the tip, and also by the emergence of the filament from the sheath, with subsequent breaking up into individual non-motile cells (conidia).

Habitat: Water.

4. **Leptothrix sideropous** (Molisch) Cholodny. (*Chlamydothrix sideropous* Molisch, Die Eisenbakterien, 1910, 14; *Gallionella sideropous* Naumann, Kungl. Svenska Vetenskapsakad., *62*, 1921, 33; Cholodny, Die Eisenbakterien, Pflanzenforschung, Heft *4*, 1926, 25.) From Greek *sideros*, iron.

Short, unbranched filaments composed of rod-shaped cells of varying length, 0.6 micron in diameter.

Sheath very thin, colorless, giving an iron reaction only at the base of the filament. Attached by a broad holdfast which gives a marked iron reaction.

Habitat: Found in water, growing on submerged surfaces.

5. **Leptothrix lopholea** Dorff. (Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 33.) From Greek *lophos*, crest, tuft.

Short, slender unbranched filaments, uniform in diameter, attached to a substrate, 5 to 13 filaments arising from a common holdfast. Filaments 20 to 33 microns long, cells 0.5 by 1.0 to 1.3 microns.

Sheaths composed of ferric hydroxide dissolve completely in dilute hydrochloric acid.

Filaments creep out of the sheath as in *Leptothrix ochracea*.

Habitat: Water.

6. **Leptothrix echinata** Beger. (Cent. f. Bakt., II Abt., *92*, 1935, 401.) From Latin *echinatus*, bristled.

Similar to the preceding species, but occurring in larger colonies, 20 to 50 filaments arising from a common holdfast. Filaments are shorter (9 to 10 microns).

Sheath is thicker at the base and tapers toward the free tip of the filaments, which are slightly spiral. The sheath contains an organic matrix visible after treatment in dilute hydrochloric acid.

Habitat: Found in water, especially in manganese-bearing waters.

7. **Leptothrix epiphytica** (Migula) Chester. (*Streptothrix epiphytica* Migula,

in Engler and Prantl, Die natürl. Pflanzenfam., *1*, 1a, 1895, 38; *Lyngbya epiphytica* Hieronymus, in Kirchner, *ibid.*, 67; Chester, Manual Determ. Bact., 1901, 370; *Leptothrix volubilis* Cholodny, Cent. f. Bakt., II Abt., *61*, 1924, 292; *Chlamydothrix epiphytica* Naumann, Ber. d. Deutsch. Bot. Ges., *46*, 1928, 141.) From M.L. *epiphyticus*, epiphytic.

Long cylindrical unbranched filaments growing spirally around filaments of *Tolypothrix*, *Oedogonium*, etc. Cells rod-shaped, 1 by 2 microns.

Sheaths cylindrical, encrusted with iron.

Cells may leave the sheaths as in *Leptothrix ochracea*.

Habitat: Water.

8. **Leptothrix pseudovacuolata** (Perfiliev) Dorff. (*Spirothrix pseudovacuolata* Perfiliev, Verh. d. Int. Verein. f. theor. u. angew. Limnologie, 1925, Stuttgart, 1927; Dorff, Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 36.) From Greek, having false vacuoles.

Filaments 85 to 250 microns in length, unbranched, spirally wound, occasionally straight. Strongly encrusted with ferric hydroxide. Spirals 20 to 24 microns from crest to crest.

Cells rounded at the ends, thin-walled, granular, 1.7 to 2.8 by 3.5 to 30 microns.

Apparently heterotrophic.

Habitat: Found in bottom muds of deep lakes with very low oxygen content.

Appendix: The following simple, filamentous organisms have also been placed in the genus *Leptothrix* or appear to belong here:

Chlamydothrix thermalis Molisch. (Die Eisenbakterien in Japan. Sc. Report Tohoku J. Univ., 4 Ser. Biol., *1*, 1923, 135; *Leptothrix thermalis* Dorff, Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 38.) From hot springs in Japan.

Leptothrix hyalina (Migula) Bergey et al. (*Streptothrix hyalina* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., *1*, 1a, 1895, 38; *Chlamydothrix hyalina* Migula, Syst. d. Bakt., *2*, 1900, 1003; Bergey et al., Manual, 1st ed., 1923, 391.) From swamp water.

Leptothrix major Dorff. (Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 35.) From Spree River water near Berlin.

Leptothrix winogradskii Cataldi. (Thesis, Univ. Buenos Aires, 1939, 64.) From water.

Lieskeella bifida Perfiliev. (Perfiliev, Verh. d. internat. Vereinigung f. theoret. u. angew. Limnologie, 1925, Stuttgart, 1927; quoted from Dorff, Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 27; also designated *Lieskeella bifilaris* by Perfiliev.) From iron bearing water. Shows gliding movements similar to blue-green algae. The type species of the genus *Lieskeella* Perfiliev.

Sideromyces glomerata Naumann. (Quoted from Dorff, Die Eisenorganismen, Pflanzenforschungen, Heft 16, 1934, 27.) From swamps in the Aneboda region of Sweden. This is the type species of the genus *Sideromyces* syn. *Mycogallionella* Naumann.

Sphaerothrix latens Perfiliev. (Perfiliev, Verh. d. internat. Vereinigung f. theoret. u. angew. Limnologie, 1925, Stuttgart, 1927; quoted from Dorff, Die Eisenorganismen, Pflanzenforschung, Heft 16, 1934, 29.) From a peat bog in a small pond near Leningrad. This is the type species of the genus *Sphaerothrix* Perfiliev. Grows in disks showing a concentric structure.

FAMILY II. CRENOTHRICHACEAE HANSGIRG.*

(Österr. Bot. Ztschr., *36*, 1888, 228.)

Filaments not branched, attached to a firm substrate, showing differentiation of base and tip. Sheaths plainly visible, thin and colorless at the tip, thick and encrusted with iron at the base. Cells cylindrical to spherical, dividing in three planes to produce the spherical non-motile conidia.

Genus I. Crenothrix *Cohn.*

(Cohn, Beitr. z. Biol. d. Pflanz., *1*, Heft 1, 1870, 108; *Phragmidiothrix* Engler, Verh. Bot. Ver. Brandenb., *24*, 1882, 19.) From Greek *crenos*, spring and *thrix*, hair.

Characters as for the family.

The type species is *Crenothrix polyspora* Cohn.

1. **Crenothrix polyspora** Cohn. (Beitr. z. Biol. d. Pflanz., *1*, Heft 1, 1870, 108; *Hypheothrix kuehniana* Rabenhorst, Flora europ. algarum, Sect. II, 88; *Leptothrix kuehniana* Rabenhorst, Algen Sachsens, No. 284; *Crenothrix kuehniana* Zopf, Zur Morphologie der Spaltpilzen, 1882, 36; *Crenothrix manganifera* Jackson, Hyg. Rund., *14*, 1904, 19.) From Greek, many spores.

Long, articulated filaments, unbranched, enclosed in a sheath which becomes expanded toward the tip. The sheath is composed of organic matter encrusted with iron. Filaments, including the sheath, measure 2 to 9 microns in diameter.

Vegetative cells vary markedly in length from long cylindrical to short ovoid forms.

Conidia, spherical, 1 to 2 microns in diameter, are liberated from the expanded tips of the sheaths. They are non-motile.

Cultivation: Has not been grown on artificial media in pure culture.

Conidia may germinate upon the exterior of the sheath from which they have been liberated, giving rise to new filaments attached to the surface of the older one, presenting a simulation of false branching.

Cholodny believed *Clonothrix fusca* to be identical with *Crenothrix polyspora*. However, *Clonothrix fusca* shows genuine false branching and produces conidia by fission in only one plane, so that the filaments taper toward the tip instead of expanding (see Kolk, Amer. Jour. Bot., *25*, 1938, 11) for a clear cut differentiation of these two species.

Source: This organism is wide-spread in water pipes, drain pipes and springs where the water contains iron. It frequently fills pipes under such circumstances and causes a real nuisance. Found by Cohn in samples of water from springs in the neighborhood of Breslau, Germany.

Habitat: In stagnant and running waters containing organic matter and iron salts, growing as thick brownish or greenish masses.

* Completely revised by Prof. A. T. Henrici, University of Minnesota, Minneapolis, Minnesota, December, 1938; further revision by Prof. Robert S. Breed, New York State Experiment Station Geneva, New York, July, 1946.

FAMILY III. BEGGIATOACEAE MIGULA.*

(Arb. Bakt. Inst. Karlsruhe, *1*, 1894, 238: in part, *Leuco-Thiobacteria* Bavendamm, Die farblosen and roten Schwefelbakterien, Pflanzenforschung, Heft *2*, 1924, 102.)

Filamentous organisms, composed of chains of cells. Individual cells generally not visible without staining. Structure very similar to that of *Oscillatoriaceae*, but devoid of chlorophyll and phycocyanin. When growing in the presence of hydrogen sulfide, the filaments contain sulfur globules. Special reproductive structures unknown.

In proposing the family *Beggiatoaceae* for the two genera of this subgroup known in 1894, Migula remarked that "it would be best to combine them with the *Oscillatoriaceae* and classify them among the Schizophyta" (Arb. Bakt. Inst. Karlsruhe, *1*, 1894, 238). The same authority has stated: "Also in view of their internal structure the species of *Beggiatoa* are so similar to those in the genus *Oscillaria* that they can hardly be separated generically" (in Engler and Prantl, Die natürl. Pflanzenfam., *1*, 1a, 1895, 41).

Since then, the close relationship between the filamentous, colorless sulfur bacteria and the blue-green algae of the family *Oscillatoriaceae* has become increasingly clear. A particularly important line of evidence is supplied by the discovery of sulfur bacteria paralleling each of the major genera of the *Oscillatoriaceae*. The family *Beggiatoaceae* Migula is retained for these filamentous sulfur bacteria. Taxonomically they could readily be classified as colorless members of the class *Schizophyceae*.

Key to the genera of family **Beggiatoaceae.**

I. Filaments non-motile. Grow attached by means of holdfast at base.
Genus I. *Thiothrix*, p. 988.

II. Filaments motile, like *Oscillatoria*, by creeping or sliding movements along a solid substrate. Not attached.
- A. Occurring singly, not embedded in a common slime-sheath.
  1. Filaments straight or bent, but not permanently coiled.
  Genus II. *Beggiatoa*, p. 990.
  2. Filaments coiled or spirally wound.
  Genus III. *Thiospirillopsis*, p. 993.
- B. Occurring in bundles, embedded in a common slime-sheath.
  Genus IV. *Thioploca*, p. 993.

Genus I. **Thiothrix** *Winogradsky.*

(Beitr. z. Morph. u. Physiol. d. Bakt., I, Schwefelbacterien, Leipsig, 1888, 39.) From Greek *theion*, sulfur, and *thrix*, hair.

Filaments non-motile, segmented, with a delicate sheath, and differentiated into base and tip. Grow attached at base to solid objects by means of gelatinous holdfast. Reproduction by transverse fission of the segments, and by rod-shaped so-called conidia, probably arising by the apical segments becoming free. Temporarily, the conidia show creeping motility, settle on solid objects, and grow out into new filaments.

The type species is *Thiothrix nivea* (Rabenhorst) Winogradsky.

The following key to the species of the genus *Thiothrix* is based upon the diameter

---

* Completely revised by Prof. C. B. Van Niel, Hopkins Marine Station, Pacific Grove, California, January, 1944.

of the filaments and their habitat, the only criteria used by previous authors for the differentiation of the seven published species. The validity of these distinguishing characteristics is, however, doubtful because their constancy has not been sufficiently established; so far the morphology of the *Thiothrix* species has not been studied in pure cultures.

Key to the species of genus **Thiothrix.**

I. Found in fresh water environments.
  A. Diameter of filaments about 2 (1.4 to 3.0) microns.
    1. *Thiothrix nivea.*
  B. Diameter of filaments about 1 micron.
    2. *Thiothrix tenuis.*
  C. Diameter of filaments less than 0.5 micron.
    3. *Thiothrix tenuissima.*
II. Found in marine environments.
  A. Diameter of filaments averages about 20 microns (actual range 15 to 30 microns).
    4. *Thiothrix voukii.*
  B. Diameter of filaments about 4 (4.4 to 6.6) microns. Segments about 25 microns long.
    5. *Thiothrix longiarticulata.*
  C. Diameter of filaments about 3 (1.8 to 5) microns. Segments about 1 micron long.
    6. *Thiothrix annulata.*
  D. Diameter of filaments about 1 (0.8 to 1.3) micron.
    7. *Thiothrix marina.*

1. **Thiothrix nivea** (Rabenhorst) Winogradsky. (*Beggiatoa nivea* Rabenhorst, Flora europaea algarum, *2*, 1865, 94; *Leptotrichia nivea* De Toni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 934; *Symphyothrix nivea* Wartman and Schenk, Schweiz. Kryptogamenflora; Winogradsky, Beitr. z. Morph. u. Physiol. d. Bact., I, Schwefelbacterien, 1888, 39.) From Latin *niveus*, snowy.

Filaments with a thin sheath, diameter 2.0 to 3.0 microns at base, 1.7 microns in the middle, 1.4 to 1.5 microns at tip. As long as the filaments contain sulfur globules, segmentation is invisible; length of segments 4 to 15 microns, the longer ones usually near apex, the shorter ones near base.

Motile segments (so-called conidia) mostly single, 8 to 15 microns long, sometimes in short filaments of 2 to 4 cells and up to 40 microns long. These segments may settle and develop near the base of the mother filament or on a filament itself, forming verticillate structures. These have been described as *Thiothrix nivea* var. *verticillata* Miyoshi (Jour. Coll. Sci., Imp. Univ. Tokyo, *10*, 1897, 156).

Habitat: Fresh water environments where hydrogen sulfide is present (sulfur springs, stagnant pools, on submerged decaying vegetation, etc.).

2. **Thiothrix tenuis** Winogradsky. (*Beggiatoa alba* var. *uniserialis* Engler, Üb. die Pilz-Vegetation des weissen oder todten Grundes in der Kieler Bucht, 1883, 4; Winogradsky, Beitr. z. Morph. u. Physiol. d. Bact., I, Schwefelbacterien, 1888, 40.) From Latin *tenuis*, slender.

Filaments about 1.0 micron in diameter, of nearly uniform thickness. Often in dense, felted masses. Segments 4 to 5 microns long.

Habitat: Fresh water environments

where hydrogen sulfide occurs. According to Bavendamm (Die farblosen u. roten Schwefelbakt., Pflanzenforschung, Heft 2, 1924, 107) also found in sea water.

3. **Thiothrix tenuissima** Winogradsky. (Beitr. z. Morph. u. Physiol. d. Bact., I, Schwefelbacterien, 1888, 40; *Thiothrix minutissima* Uphof, Arch. f. Hydrobiol., *18*, 1927, 77.) From Latin *tenuis*, diminutive, very slender.

Filaments less than 0.5 micron in diameter, usually in dense masses.

Habitat: Fresh water environments where hydrogen sulfide occurs.

4. **Thiothrix voukii** Klas. (Arch. f. Protistenk., *88*, 1936, 123.) Named for Vouk, a Russian scientist.

Filaments 15 to 30, most frequently 17 microns in diameter, of rather uniform thickness. Segments visible without special treatment. Segments generally somewhat longer than wide, rarely square, occasionally barrel-shaped. Length of segments 15 to 30, mostly 19 to 23 microns. Motile segments not yet observed.

Apart from the lack of motility, this species closely resembles the motile *Beggiatoa mirabilis*.

Source: Found in effluent of sulfur springs at seashore near Split, Jugoslavia. So far reported only once.

Habitat: Marine environments containing hydrogen sulfide.

5. **Thiothrix longiarticulata** Klas. (Arch. f. Protistenk., *88*, 1936, 126.) From Latin *longus*, long and *articulatus*, jointed.

Filaments 3.3 to 6.6, most frequently 4.2 microns in diameter, of uniform thickness. Occur in dense, felted masses. Segments long, measuring 19 to 33, mostly 26 microns in length. Sulfur droplets usually absent in the proximity of cross-walls. Motile segments not yet reported.

Source: Found in effluent of sulfur springs at seashore near Split, Jugoslavia. So far reported only once.

Habitat: Marine environments containing hydrogen sulfide.

6. **Thiothrix annulata** Molisch. (Cent. f. Bakt., II Abt., *33*, 1912, 58.) From Latin *annulatus*, ringed.

Filaments 3 to 4, occasionally up to 5 microns in diameter, thinner at base (2 microns) and at tip (1.8 microns). Segments only about 1 micron in length. Often found with narrow bands which are free of sulfur, thus giving a ringed appearance to the filaments. Old filaments may show spacial thickening and distortion, but this is not characteristic for the species.

Habitat: Marine environments containing hydrogen sulfide; frequently on decaying algae.

7. **Thiothrix marina** Molisch. (Cent. f. Bakt., II Abt., *33*, 1912, 58.) From Latin *marinus*, pertaining to the sea.

Filaments about 1 (0.8 to 1.3) micron in diameter, of rather uniform thickness. Usually in felted masses.

Resembles *Thiothrix tenuis*. Since the latter has been reported from marine environments (Bavendamm, Die farblosen u. roten Schwefelbakterien, Pflanzenforschung, Heft 2, 1924, 107), *Thiothrix marina* may not be an independent species, but identical with *Thiothrix tenuis*.

Habitat: Marine (?) environments containing hydrogen sulfide; frequently on decaying algae.

Genus II. **Beggiatoa** *Trevisan.*

(Prospetto della Flora Euganea, 1842, 56.) Named for the Vicenza physician, F. S. Beggiato.

Filamentous, motile, segmented organisms, occurring singly or in white to creamy felted masses in which the separate filaments retain their individuality. Not at-

tached. Existence of a sheath not definitely established. Movements of the filaments dependent upon a solid substratum over which they slide in the same manner as species of *Oscillatoria*. Sliding movements often accompanied by rotation of filaments around long axis. Reproduction by transverse fission of segments; the filaments may also break up into smaller units, each continuing a separate existence. The latter mode of multiplication corresponds to that by means of the so-called motile conidia or segments in *Thiothrix*.

The type species is *Beggiatoa alba* (Vaucher) Trevisan.

In this genus, also, the species so far described are differentiated on the basis of dimensions. The range of sizes for separate species appears, in most cases, quite arbitrary, especially in view of the existence of practically all intermediate stages. Since the smaller forms have been found both in fresh water and marine environments (Bavendamm, Die farblosen u. roten Schwefelbakterien, Pflanzenforschung, Heft 2, 1924, 104), the previously described *Beggiatoa marina* has been omitted as a separate species. Pure culture studies may establish more staisfactory methods of differentiation and a better understanding of speciation.

Key to the species of genus **Beggiatoa.**

I. Diameter of filaments greater than 25 microns.
    1. *Beggiatoa gigantea.*
II. Diameter of filaments less than 25 microns.
    A. Diameter of filaments greater than 15 microns.
        2. *Beggiatoa mirabilis.*
    B. Diameter of filaments less than 15 microns.
        1. Diameter of filaments greater than 5 microns.
            3. *Beggiatoa arachnoidea.*
        2. Diameter of filaments less than 5 microns.
            a. Diameter of filaments greater than 2.5 microns.
                4. *Beggiatoa alba.*
            aa. Diameter of filaments less than 2.5 microns.
                b. Diameter of filaments greater than 1 micron.
                    5. *Beggiatoa leptomitiformis.*
                bb. Diameter of filaments less than 1 micron.
                    6. *Beggiatoa minima.*

1. **Beggiatoa gigantea** Klas. (Arch. f. Mikrobiol., *8*, 1937, 318; includes the arge forms of *Beggiatoa mirabilis* Cohn, Hedwigia, *4*, 1865, 81.) From Greek *gigas*, giant.

Filaments 26.4 to 55, average 35 to 40 microns in diameter. Klas, in his diagnosis, gives 26.4 to 42.9 microns as dimensions. This would exclude the largest forms of *Beggiatoa mirabilis* described by Hinze (Ber. d. deut. bot. Ges., *19*, 1901, 369). Since the proposal of a separate species for such organisms appears at present unjustified, the maximum diameter has here been increased. Filaments clearly segmented; length of segments 5 to 13, average 8.5 microns. Terminal cells rounded or tapering.

When the filaments are in healthy condition they are of uniform width; bulging of the sides indicates unfavorable conditions.

Habitat: Apparently restricted to marine environments containing hydrogen sulfide. Frequent on decaying marine algae.

2. **Beggiatoa mirabilis** Cohn *emend.* Klas. (Cohn, Hedwigia, *4*, 1865, 81;

Klas, Arch. f. Mikrobiol., *8*, 1937, 318.) From Latin *mirabilis*, wonderful.

Filaments 15 to 21.5, average 17 microns in diameter. The so-defined species does not overlap with *Beggiatoa gigantea* according to Klas (*loc. cit.*). Segmentation usually observable without special treatment; segments 5 to 13, average 8.5 microns long. Terminal cells rounded or tapering, sometimes bent.

When the filaments are in healthy condition they are of uniform width; an unfavorable environment induces bulging of the sides.

Habitat: Apparently restricted to marine environments containing hydrogen sulfide. Common on decaying marine algae.

Uphof (Arch. f. Hydrobiol., *18*, 1927, 83) has created a species, *Beggiatoa maxima*, which on account of its diameter (10 to 20 microns) falls partly within the range of *Beggiatoa mirabilis*, partly within *Beggiatoa arachnoidea*. Since it was found in a fresh water environment, the habitat of *Beggiatoa mirabilis* may not be restricted to marine media.

3. **Beggiatoa arachnoidea** (Agardh) Rabenhorst. (*Oscillatoria arachnoidea* Agardh, Regensburger Flora, 1827, 634; Rabenhorst, Flora europaea algarum, 1865, 94; *Beggiatoa pellucida* Cohn, Hedwigia, *4*, 1865, 82; ? *Oscillatoria beggiatoides* Arzichowsky, Bull. Jard. Imp. Bot., St. Pétersb., *2*, 1902, 38, 47; includes the larger members of *Beggiatoa major* Winogradsky, Beitr. z. Morph. u. Physiol. d. Bact., I, Schwefelbacterien, 1888, 25; and the smaller ones of *Beggiatoa maxima* Uphof, Arch. f. Hydrobiol., *18*, 1927, 80.) From Greek, resembling a cobweb.

Filaments 5 to 14 microns in diameter. Segmentation generally observable only after special staining or removal of sulfur globules; segments 5 to 7 microns in length. Terminal cells rounded, often tapering. Filaments of uniform width.

Habitat: Both fresh water and marine environments containing hydrogen sulfide.

4. **Beggiatoa alba** (Vaucher) Trevisan. (*Oscillatoria alba* Vaucher, Histoire des Conferves d'eau douce, 1803, 198; *Beggiatoa punctata* Trevisan, Prospetto della Flora Euganea, 1842, 56; *Beggiatoa alba* var. *marina* Cohn, Hedwigia, *4*, 1865, 83; *Beggiatoa marina* Molisch, Cent. f. Bakt., II Abt., *33*, 1912, 58; in part, *Beggiatoa major* Winogradsky, Beitr. z. Morph. u. Physiol. d. Bact., I, Schwefelbacterien, 1888, 25.) From Latin *albus*, white.

This is the type species of the genus.

Filaments 2.5 to 5, most commonly 3 microns in diameter, of even width. Segmentation difficult to detect in filaments containing many sulfur globules; segments 3 to 9 microns long, shortly after division practically square. Terminal cells rounded.

Habitat: Both fresh water and marine environments containing hydrogen sulfide.

Distribution: Ubiquitous, and probably the most common of the filamentous sulfur bacteria.

5. **Beggiatoa leptomitiformis** (Meneghini) Trevisan. (*Oscillatoria leptomitiformis* Meneghini, Delle Alghe viventi nelle terme Euganee, 1844, 122; Trevisan, Prospetto della Flora Euganea, 1842, 56; *Beggiatoa media* Winogradsky, Beitr. z. Morph. u. Physiol. d. Bact., I, Schwefelbacterien, 1888, 25.) From Greek *leptos*, small and *mitos*, thread and Latin *forma*, shape.

Filaments 1 to 2.5 microns in diameter, of uniform width. Segmentation only observable after removal of sulfur globules; segments 4 to 8 microns in length. Terminal cells usually rounded.

Habitat: Fresh water and marine environments containing hydrogen sulfide.

6. **Beggiatoa minima** Winogradsky. (Winogradsky, Beitr. z. Morph. u. Physiol. d. Bacterien, I. Schwefelbacterien, 1888, 25; *Beggiatoa minor* Uphof, Arch. f. Hydrobiol., *18*, 1927, 79; not *Beggiatoa minima* Warming, Om Nogle ved Danmarks Kyster levende Bakterier, 1876, 52, which from the description is not a *Beggiatoa.*) From Latin *minimus*, least.

Filaments less than 1 micron in diameter, of uniform width. Normally appears unsegmented; length of segments about 1 micron.

Habitat: Fresh water and marine environments containing hydrogen sulfide.

Genus III. Thiospirillopsis *Uphof.*

(Arch. f. Hydrobiol., *18*, 1927, 81.) From Greek *theion*, sulfur M.L. *spirillum*, spirillum and Greek *opsis*, appearance.

Filamentous, colorless sulfur bacteria, segmented, and spirally wound. Exhibit creeping motility, combined with rotation, so that the filaments move forward with a corkscrew-like motion. The tips produce oscillating movements. Resembles *Spirulina* among the *Oscillatoriaceae.*

The type species is *Thiospirillopsis floridana* Uphof.

1. **Thiospirillopsis floridana** Uphof. (Arch. f. Hydrobiol., *18*, 1927, 83.) Named from Florida, the place where it was first found.

Filaments 2 to 3 microns in diameter. Segmentation difficult to observe without special precautions; segments about 3 to 5 microns long. The spiral windings are regular.

Source: Found in the sulfur spring water at Wekiwa Springs and Palm Springs, Florida. A very similar organism has been observed at Pacific Grove, California, in a marine aquarium where hydrogen sulfide had been generated by sulfate reduction. The genus *Thiospirillopsis* may, therefore, be more wide-spread than is generally believed.

Habitat: Probably widely distributed in water containing sulfur.

Genus IV. Thioploca *Lauterborn.*

(Ber. d. deut. botan. Ges., *25*, 1907, 238.) Name derived from Greek *theion*, sulfur, and *ploka*, braid.

Filaments of *Beggiatoa*-like appearance, but occurring in parallel or braided bundles, enclosed by a common wide slime-sheath. The latter is frequently incrusted on the outside with detritus. Within the sheath the individual filaments are motile in the manner of *Beggiatoa*; the filaments are segmented, the terminal segments often tapering.

Resembles closely the genera *Hydrocoleus* and *Microcoleus* among the *Oscillatoriaceae.*

It is doubtful whether the members of the genus *Thioploca* are true colorless sulfur bacteria; most investigators of these forms have reported a greenish-blue coloration of the filaments. Only the regular occurrence of sulfur droplets in filaments taken from their natural habitat stamps the organisms as sulfur bacteria. In view of the close relationship of the *Beggiatoaceae* to the blue-green *Oscillatoriaceae*, this is, however, a minor issue.

Four species have been described to date. Three correspond, with respect to the individual filaments, to *Beggiatoa arachnoidea*, *Beggiatoa alba*, and *Beggiatoa leptomitiformis* respectively; the fourth appears to be a combination of the first and third

species of *Beggiatoa* in a common sheath. This occurrence of two distinct species of *Beggiatoa* in a common sheath makes the genus a doubtful taxonomic entity.

The type species is *Thioploca schmidlei* Lauterborn.

Key to the species of genus **Thioploca.**

I. Filaments in a common sheath of fairly uniform diameter.
  A. Diameter of individual filaments 5 to 9 microns.
    1. *Thioploca schmidlei.*
  B. Diameter of individual filaments 2 to 5 microns.
    2. *Thioploca ingrica.*
  C. Diameter of individual filaments 1 to 2 microns.
    3. *Thioploca minima.*

II. Filaments in common sheath of greatly different diameter.
    4. *Thioploca mixta.*

1. **Thioploca schmidlei** Lauterborn. (Ber. d. deut. bot. Ges., *25*, 1907, 238.) Named for Mr. Schmidle.

Individual filaments in a common sheath 5 to 9 microns in diameter, clearly segmented. Segments 5 to 8 microns in length. Mucilaginous sheath 50 to 160 microns in diameter. Number of filaments embedded in one sheath variable.

Source: Various localities in Central Europe.

Habitat: So far reported only in fresh water mud, containing hydrogen sulfide and calcium carbonate.

2. **Thioploca ingrica** Wislouch. (Ber. d. deut. bot. Ges., *30*, 1912, 470.) From *Ingria*, an ancient district of Leningrad.

Individual filaments in common sheath 2 to 4.5 microns in diameter, clearly segmented. Segments 1.5 to 8 microns in length. Mucilaginous sheath up to 80 microns in diameter. Number of filaments in one sheath variable.

Source: Various localities in Central Europe.

Habitat: Found in fresh water and marine mud containing hydrogen sulfide.

3. **Thioploca minima** Koppe. (Arch. f. Hydrobiol., *14*, 1923, 630.) From Latin *minimus*, least.

Individual filaments in a common sheath 0.8 to 1.5 microns in diameter, segmentation generally observable only after removal of sulfur droplets. Segments 1 to 2 microns long. Mucilaginous sheath up to 30 microns in diameter. Number of filaments in one sheath variable.

Source: Various localities in Central Europe.

Habitat: Fresh water and marine mud containing hydrogen sulfide.

4. **Thioploca mixta** Koppe. (Arch. f. Hydrobiol., *14*, 1923, 630.) From Latin *mixtus*, mixed.

Individual filaments in a common sheath of two clearly different sizes, comprizing both filaments of 6 to 8 microns, and filaments of about 1 micron in diameter. The former are clearly segmented, with segments of 5 to 8 microns in length. In the latter segmentation is visible after removal of sulfur droplets; segments 1 to 2 microns long. Mucilaginous sheath usually about 50 microns thick. Number of filaments in one sheath variable.

Source: Reported so far only from Lake Constanza.

Habitat: Fresh water mud containing hydrogen sulfide.

Appendix: In addition to the above genera and species, a number of insufficiently characterized, filamentous sulfur bacteria which may be related to the

Beggiatoaceae have been described under various names as follows:

Conidiothrix sulphurea Petersen. (Dansk Botan. Arkiv., *1*, 1921, 1.)

Filamentous, nonmotile organisms, of uniform width, between 0.5 and 1 micron in diameter, covered on the outside with sulfur. Segmentation not reported. The outstanding characteristic of the genus *Conidiothrix* is the supposed multiplication of the filaments by means of conidia which arise by budding on the filament. Apart from this reported occurrence of a budding process, the description is similar to that of *Leptothrix sulphurea* and of *Thiothrix tenuis* and *Thiothrix tenuissima*. Since consecutive observations on growing organisms are lacking, it seems advisable to consider *Conidiothrix sulphurea* as probably identical with *Thiothrix tenuis* or *Thiothrix tenuissima*.

Leptothrix sulphurea Miyoshi. (Jour. Coll. Sci., Imp. Univ. Tokyo, Japan, *10*, 1897, 154.)

Filamentous, non-motile organisms, of uniform width, not exceeding 0.7 micron in diameter. The filaments are covered on the outside with a powdery deposit of elementary sulfur. Segmentation observable only after special staining; length of segments not published.

Found by Miyoshi in sulfur springs in Japan. Although not reported as containing sulfur globules inside the filaments, the description would closely fit *Thiothrix tenuis* or *Thiothrix tenuissima* Winogradsky. The latter have been observed in masses covered on the outside with elementary sulfur. Therefore, it seems likely that *Leptothrix sulphurea* is a synonym for *Thiothrix tenuis* or *Thiothrix tenuissima*.

Thionema vaginatum Kolkwitz. (Ber. d. deut. bot. Ges., *56*, 1938, 11.)

The type species of the genus *Thionema*.

Described as a filamentous, colorless sulfur bacterium, non-motile, attached in the manner of *Thiothrix*. Filaments 1.5 to 2 microns in diameter, segmented. Segments 2 to 5 microns long. Reproduction, as in the case of *Thiothrix*, by means of detached segments.

While this part of the description fits that of *Thiothrix nivea*, the new generic name was proposed on the basis of the occurrence of a distinct sheath, frequently impregnated with iron compounds. Since Winogradsky mentions the occurrence of a sheath also in *Thiothrix nivea*, it seems desirable to consider *Thionema vaginatum*, at least for the time being, as a probable synonym of *Thiothrix nivea*.

Source: Found on waterplants in the Teltow-Canal near Berlin, the water containing hydrogen sulfide and iron salts.

Thiosiphon adriaticum Klas. (Sitzungsber. Akad. d. Wissensch. Wien, Mathem.-naturw. Kl., I, *145*, 1936, 209.)

Described as a filamentous sulfur bacterium, non-motile, but without segmentation, hence tubular and unicellular. Multiplication by means of conidia arising from restriction of the apical part of the cell. Length of filament about 1 to 1.5 mm, width 17 to 53 microns, usually tapering towards apex. Conidia 13 to 30 microns by 30 to 50 microns.

The description is at variance with the appearance of the organism in the published photomicrograph in so far as the size of the conidia is concerned. From the photomicrograph this appears to be about 30 by 200 microns. The entire appearance is strongly reminiscent of that of *Beggiatoa mirabilis* (*Beggiatoa gigantea*) in certain cultures. The short conidia, described in the text, strikingly resemble species of *Achromatium*. Consecutive observations on growing cultures of *Thiosiphon* do not appear to

have been made. Since (a) the internal structure of the large *Beggiatoaceae* is easily damaged, (b) the segmentation in living individuals is difficult to observe when the filaments are filled with sulfur, (c) the presence of *Achromatium* in the locality from which *Thiosiphon* was collected is almost certain, and (d) the developmental cycle is merely a reconstruction of simultaneously observed elements, considerable doubt as to the validity of the genus appears justified.

* **Appendix I:** The group of large, unicellular, colorless sulfur bacteria is placed here as a single family, *Achromatiaceae* Massart as in previous editions of the MANUAL. It includes organisms which are similar in physiology to the *Beggiatoaceae*.

Massart (Rec. Inst. Bot. Univ. Bruxelles, *5*, 1902, 251) proposed the family *Achromatiaceae* for the bacteria described by Schewiakoff (Über einen neuen bacterienähnlichen Organismus des Süsswassers, Habilitationsschrift, Heidelberg, 1893) as *Achromatium oxaliferum*. The family diagnosis was modified by Nadson (Jour. Microbiol., St. Pétersb., *1*, 1914, 72) and by Nadson and Wislouch (Bull. Princip. Jard. Bot. Républ. Russe, *22*, 1923, 33) to include the genera *Thiophysa* and *Thiosphaerella*.

In this form, the family represents a homogeneous group of organisms, all characterized by a pronounced similarity in cell-shape, structure, method of reproduction and motility. They exhibit very slow, jerky and rotating movements, but are devoid of flagella or other visible organs of locomotion. They closely resemble the blue-green algae of the genus *Synechococcus*, even in size.

By including the genus *Thiospira* in the family *Achromatiaceae*, Buchanan (Jour. Bact., *3*, 1918, 462) modified the diagnosis to read:

Unicellular, large, motile (by means of flagella?). Cells containing granules of sulfur (or in one form possibly oxalate) but no bacteriopurpurin.

Thus was proposed a family in which the spiral sulfur bacteria, indubitably related to species of *Spirillum* among the *Eubacteriales*, were linked with the taxonomically obscure species included in *Achromatium* and *Thiophysa*. Four genera, *Achromatium*, *Thiophysa*, *Thiospira* and *Hillhousia* were recognized.

Bavendamm (Die farblosen und roten Schwefelbakterien, Pflanzenforschung, Heft 2, 1924, 109), following the same trend, also combined all non-filamentous forms of the colorless sulfur bacteria into a family *Achromatiaceae*, with the diagnosis: Cells free, motile. As he realized that *Hillhousia* should be regarded as a synonym of *Achromatium* and added the genus *Thiovulum* Hinze (Ber. d. deut. bot. Ges., *31*, 1913, 195), four genera were again included in the family. *Thiosphaerella* was added as an appendix to *Thiophysa*.

Thiovulum is morphologically similar to *Achromatium*, *Thiophysa*, and *Thiosphaerella* with respect to cell size and structure, but differs conspicuously in being actively and rapidly motile. The manner of locomotion suggests the presence of polarly inserted flagella. However, these have never been demonstrated convincingly.

While it is conceivable that a relationship exists between *Thiovulum* and the organisms of the *Achromatium* type, the combination of the representatives into one family should be regarded as tentative and open to question. There certainly is no justification at present for including the sulfur spirilla in this family. These are placed in this edition of the MANUAL in *Spirilleae* among the *Eubacteriales*.

* **Completely revised by Prof. C. B. Van Niel, Hopkins Marine Station, Pacific Grove, California, January, 1944.**

FAMILY A. ACHROMATIACEAE MASSART.

(Rec. Inst. Bot. Univ. Bruxelles, *5*, 1902, 251.)

Cells large, spherical to ovoid in shape, sometimes rod-shaped, may contain globules of sulfur and/or calcium carbonate crystals. Do not possess photosynthetic pigments. Fresh water and marine forms.

A satisfactory differentiation of the genera *Achromatium*, *Thiophysa*, and *Thiosphaerella* is at present well-nigh impossible. They have here been combined into a single genus, *Achromatium*.

Achromatium mobile Lauterborn (Verhandl. Natur-histor.-Mediz. Vereins Heidelberg, N.F., *13*, 1915, 413) is fundamentally different from the other members of the genus. It possesses a clearly visible polar flagellum, suggesting its close affinity with the *Pseudomonadaceae* among the *Eubacteriales*. Whether it is a true sulfur bacterium has not been established with certainty; this appears very doubtful in the case of the two similar forms described as *Pseudomonas bipunctata* and *Pseudomonas hyalina* by Gicklhorn (Cent. f. Bakt., II Abt., *50*, 1920, 425, 426). Utermöhl and Koppe (Verhandl. Intern. Ver. f. theoret. u. angew. Limnologie, 1913, 86 and Archiv f. Hydrobiol., Suppl. Bd. *5*, 1925, 234) have proposed the generic name *Macromonas* for this group. This has been adopted here.

All of the above mentioned organisms have so far been studied exclusively as found in their natural habitats. Pure culture studies are greatly needed. These may show that the peculiar calcium carbonate inclusions (not calcium oxalate as thought by Schewiakoff, nor calcium thiosulfate as believed by Hannevart) in *Achromatium oxaliferum* and in *Macromonas bipunctata* occur only under special environmental conditions.

Key to the genera of family **Achromatiaceae.**

I. Large, ovoid to spherical organisms, normally containing sulfur globules when found in the presence of hydrogen sulfide.
  A. Non-motile, or slowly, jerkily sliding across the substrate.
    Genus I. *Achromatium*, p. 997.
  B. Actively motile, independent of the substrate.
    Genus II. *Thiovulum*, p. 999.
II. Rod-shaped and curved organisms, motile by means of polar flagella.
  A. Bean-shaped to short rod-shaped organisms which may contain small sulfur globules, but are chiefly characterized by large, round spherules of calcium carbonate as cell inclusions. The polar flagellum is often visible in the larger forms without special staining.
    Genus III. *Macromonas*, p. 1000.

Genus I. **Achromatium** *Schewiakoff.*

(Schewiakoff, Üb. einen neuen bacterienähnlichen Organismus des Süsswassers, Habilitationsschr., Heidelberg, 1893; *Modderula* Frenzel, Biol. Centralbl., *17*, 1897, 801; *Hillhousia* West and Griffiths, Proc. Roy. Soc., B, *81*, 1909, 389). From Greek *a*, without and *chroma*, color.

Thiophysa Hinze (Ber. d. deut. bot. Ges., *21*, 1903, 309) and *Thiosphaerella* Nadson (Jour. Microbiol., St. Pétersb., *1*, 1914, 72) are also included in the genus as defined here.

Unicellular organisms with large cells, shortly cylindrical with hemispherical extremities, also ellipsoidal to spherical. Cells divide by a constriction in the

middle. Movements, if any, are of a slow, rolling, jerky type and are dependent upon the presence of a substrate. No special organs of locomotion are known. In their natural habitat, the cells contain sulfur droplets and sometimes additional inclusions, such as large spherules of calcium carbonate.

The type species is *Achromatium oxaliferum* Schewiakoff.

It is not easy as yet to determine whether several species should be recognized in this genus. There appears to be some justification for differentiating between the forms which contain the characteristic and conspicuous calcium carbonate inclusions and forms in which these large spherules are lacking. The former have been reported mostly from fresh or brackish water environments, while the characteristic habitat of the latter seems to be marine. It is, of course, probable that the internal deposition of calcium carbonate depends upon the composition of the environment, so that the distinction may prove arbitrary and non-specific.

Achromatium cells of widely different sizes have been described. Schewiakoff (Üb. einen neuen bacterienähnlichen Organismus des Süsswassers, Habilitationsschrift, Heidelberg, 1893) mentions a variation of 15 to 43 microns in length, and 9 to 22 microns in width for *Achromatium oxaliferum*. Larger cells have been observed by Warming (Videnskab. Meddel. naturhistor. Foren., Kjöbenhavn, 1875, No. 20–28, 360; size to 85 microns), and by Virieux (Ann. Sci. Natur., Sér. 9, *18*, 1913, 265; size to 95 microns in length).

Nadson (Bull. Jard. Imp. Botan., St. Pétersb., *13*, 1913, 106; Jour. Microb., St. Pétersb., *1*, 1914, 52) proposed the name *Achromatium gigas* for the larger organisms; also West and Griffiths (Ann. Bot., *27*, 1913, 83) created two species, *Hillhousia mirabilis*, with sizes of 42 to 86 microns long by 20 to 33 microns wide, and *Hillhousia palustris*, measuring on the average 14 by 25 microns, for the same group of sulfur bacteria.

However, Bersa (Sitzungsber. Akad. Wiss., Wien, Mathem.-naturw. Kl., I, *129*, 1920, 233) observed so many intermediate sizes that he recognized only a single species. Nadson and Wislouch (Bull. Princ. Jard. Botan., Républ. Russe, *22*, 1923, Suppl. 1, 33) arrived at the same conclusion, and this view is accepted here.

The marine *Achromatium* types which do not contain calcium carbonate crystals, also have been segregated into species on the basis of their size. Here again, there does not seem to be any valid reason for maintaining several species as there is a continuous series of intermediate forms.

Thus, the organisms previously described as *Achromatium oxaliferum*, *Achromatium gigas*, *Hillhousia mirabilis* and *Hillhousia palustris* are provisionally treated here as one species, while the marine counterpart, *Thiophysa volutans*, is combined with *Thiophysa macrophysa* and *Thiosphaerella amylifera*, all three being regarded as *Achromatium volutans*.

Key to the species of genus **Achromatium.**

I. Organisms characteristically containing calcium carbonate crystals in the form of highly refractile, large spherules. Occur mostly in fresh water and brackish muds.

1. *Achromatium oxaliferum*.

II. Organisms naturally occurring without such calcium carbonate inclusions. Found in marine mud.

2. *Achromatium volutans*.

1. **Achromatium oxaliferum** Schewiakoff. (Schewiakoff, Üb. einen neuen bacterienähnlichen Organismus des Süsswassers, Habilitationsschrift, Heidelberg, 1893; *Modderula hartwigi* Frenzel, Biol. Centralbl., *17*, 1897, 801; *Hillhousia mirabilis* West and Griffiths, Proc. Roy. Soc., B, *81*, 1909, 389; *Hillhousia palustris* West and Griffiths, Ann. Bot., *27*, 1913, 83; *Achromatium gigas* Nadson, Bull. Jard. Imp. Bot., St. Pétersb., *13*, 1913, 106). From Latin *oxalis*, intended to refer to the supposed presence of oxalate crystals and *fero*, to bear.

Unicellular organisms, varying in shape from spherical or ovoid to shortly cylindrical with hemispherical extremities. Division by constriction in the middle. Cells vary in size from spheres of about 7 microns or even less in diameter to giant forms 100 microns long by 35 microns wide. The extremes are connected by a continuous series of intermediate sizes.

Organisms may show motility of a jerky and rotating kind, always very slow, and dependent upon a substrate. Typical organs of locomotion absent.

Normally contain small sulfur globules, accompanied by much larger calcium carbonate crystals, the latter in the form of large highly refractile spherules. Under favorable environmental conditions these may disappear before the sulfur globules. Cells with calcium carbonate inclusions have a very high specific gravity. They are, therefore, found only in the bottom of pools, streams, etc., usually in the mud.

Strictly microaerophilic, and apparently require hydrogen sulfide.

Habitat: Fresh water and brackish mud containing hydrogen sulfide and calcium salts. According to Nadson and Wislouch (Bull. princip. Jard. bot., Républ. Russe, *22*, 1923, Suppl. 1, 33) also in marine mud.

2. **Achromatium volutans** (Hinze) *comb. nov.* (*Thiophysa volutans* Hinze, Ber. d. deut. bot. Ges., *21*, 1903, 309; *Thiophysa macrophysa* Nadson, Bull. Jard. Imp. Bot., St. Pétersb., *13*, 1913, 106 and Jour. Microb., St. Pétersb., *1*, 1914, 54; *Thiosphaerella amylifera* Nadson, Bull. Jard. Imp. Bot., St. Pétersb., *13*, 1913, 106 and Jour. Microb., St. Pétersb., *1*, 1914, 54.) From Latin *volutans*, rolling.

Unicellular organisms, spherical to ovoid in shape, dividing by constriction in the middle. Size variable, ranging from spheres about 5 microns in diameter to ovoids up to 40 microns in length.

Cells may show motility of a jerky and rotating kind, always very slow, and dependent upon a substrate. Typical organs of locomotion absent.

Normally contain sulfur globules, but lack large internal calcium carbonate deposits.

Microaerophilic, apparently requiring hydrogen sulfide.

Habitat: Marine mud containing hydrogen sulfide; decaying seaweeds.

Genus II. **Thiovulum** *Hinze.*

(Ber. d. deut. bot. Ges., *31*, 1913, 195.) From Greek *theion*, sulfur and Latin *ovum*, egg.

Unicellular organisms, round to ovoid. Cytoplasm often concentrated at one end of the cell, the remaining space being occupied by a large vacuole. Multiplication by constriction which, in late stages, merges into fission. Actively motile; movements accompanied by rapid rotation. Flagellation not definitely demonstrated, but type of locomotion suggests polar flagellation. Normally contain sulfur globules in the cytoplasm, hence, these are frequently concentrated at one end of the cell.

The type species is *Thiovulum majus* Hinze.

As in the case of *Achromatium*, it is difficult to establish distinct species. Those that have been described differ only in size, and the differences appear to be far from constant. For *Thiovulum* (*Monas*) *mülleri* (Warming) Lauterborn (Verhandl. Naturhist.-medizin. Vereins, Heidelberg, N. F., *13*, 1915, 414) the diameter is stated by Warming (Videnskab. Meddel. naturhistor. Foren., Kjöbenhavn, 1875, No. 20–28, 363), Hinze (Ber. d. deut. bot. Ges., *31*, 1913, 191) and Lauterborn (*loc. cit.*, 415) respectively to be 5.6 to 15, 13 to 15 and 5 to 13 microns. The ovoid cells of *Thiovulum majus* are noted as being 11 to 18 microns long and 9 to 17 microns wide, while *Thiovulum minus* comprises the smaller forms from 9.6 to 11 microns long by 7.2 to 9 microns wide. In view of the regular occurrence of all intermediate sizes it seems best to recognize only a single species at present.

1. **Thiovulum majus** Hinze. (Hinze, Ber. d. deut. bot. Ges., *31*, 1913, 195; including *Thiovulum minus* Hinze, *idem.*; *Monas mulleri* Warming, Videnskab. Meddel. naturhistor. Foren., Kjöbenhavn, 1875, No. 20–28, 363; *Achromatium mulleri* Migula, Syst. d. Bakt. *2*, 1900, 1038; *Thiovulum mulleri* Lauterborn, Verhandl. Naturhist.-medizin. Vereins, Heidelberg, N.F., *13*, 1915, 414.) From Latin *major*, large.

Unicellular organisms, spherical to ovoid. Cytoplasm often concentrated at one end of the cell, the remainder being occupied by a vacuole. Multiplication by constriction which, in late stages, merges into fission. Size of cells, 5 to 20 microns in diameter.

The most characteristic feature is its motility; it is the only one of the spherical to ovoid, colorless sulfur bacteria capable of rapid movement. Flagellation has not been definitively demonstrated, but the type of locomotion suggests the presence of polar flagella.

Normally contains sulfur droplets in cytoplasm, frequently concentrated at one end of cell.

Microaerophilic; apparently requires hydrogen sulfide.

Habitat: In sulfide-containing water, usually accumulating near the surface. Often in cultures of decaying algae. Both in fresh water and marine environments.

Genus III. Macromonas *Utermöhl and Koppe.*

(Verhandl. Intern. Ver. f. Theoret. u. angew. Limnologie, 1923, 86.) From Latin *macro*, large and *monas*, a unit or cell.

Colorless, cylindrical to bean-shaped bacteria, actively motile by means of a single polar flagellum. Multiplication by constriction (fission). Chiefly characterized by the occurrence of calcium carbonate inclusions in the form of large spherules. In their natural habitat they may also contain small sulfur globules.

The type species is *Macromonas mobilis* (Lauterborn) Utermöhl and Koppe.

Two species have primarily been distinguished on the basis of cell size. Whether this is sufficiently constant to serve as a specific character has not been definitely established. From studies still limited in scope and extent on the organisms in their natural habitat, it appears at present that the two species should be maintained, at least provisionally. It is possible, however, that further observations, especially with cultures under different environmental conditions, will show the occurrence of intermediate types and of a greater range of variation in size of pure cultures than what has previously been reported.

Key to the species of genus **Macromonas.**

I. Cells measuring 12 microns or more in length and 8 microns or more in width.
1. *Macromonas mobilis.*

II. Cells measuring less than 12 microns in length and 5 microns or less in width.
2. *Macromonas bipunctata.*

1. **Macromonas mobilis** (Lauterborn) Utermöhl and Koppe. (*Achromatium*) *mobi e* Lauterborn, Verhandl. Naturhist.-Medizin. Vereins, Heidelberg, N. F., *13*, 1915, 413; *Microspira vacillans* Gicklhorn, Cent. f. Bakt., II Abt., *50*, 1920, 422; Utermöhl and Koppe, Verhandl. Intern. Ver. f. theoret. u. angew. Limnologie, 1923, 86 and Utermöhl and Koppe, Arch. f. Hydrobiol., Suppl. Bd. *5*, 1925, 234.)

Colorless sulfur bacteria, always occurring singly, slightly curved, elongated ellipsoids or cylinders with broad hemispherical ends. Length varies from 12 to 30 microns, width from 8 to 14 microns; most common size 20 by 9 microns. Multiplication by constriction in the middle.

Cells actively motile by means of a single polar flagellum, distinctly visible without special staining. It is 20 to 40 microns long, and, with respect to the direction of motion, always posteriorly placed. Rate of movement somewhat sluggish, about 800 microns per minute, probably on account of high specific gravity of cells.

Normally contain small sulfur droplets and, in addition, large, roughly spherical inclusions of calcium carbonate. Two to four such crystal masses almost fill a single cell. Under unfavorable conditions the calcium carbonate crystals may disappear before the sulfur globules.

Microaerophilic; apparently require hydrogen sulfide.

Habitat: Fresh water environment containing sulfide and calcium ions; in shallow basins and streams in the upper layers of the mud.

2. **Macromonas bipunctata** (Gicklhorn) Utermöhl and Koppe. (*Pseudomonas bipunctata* Gicklhorn, Cent. f. Bakt., II Abt., *50*, 1920, 425; Utermöhl and Koppe, Arch. f. Hydrobiol., Suppl. Bd. *5*, 1925, 235.)

Cells colorless, occurring singly, cylindrical with hemispherical ends; after cell division often temporarily pear-shaped. Length 8 to 12 microns, width 3 to 5 microns. Multiplication by constriction in the middle.

Actively motile by means of a single polar flagellum, about 10 to 15 microns long, and always posteriorly placed with respect to the direction of movement. Flagellum delicate, not visible without staining. Rate of movement sluggish, about 600 microns per minute. Probably this slow motion is on account of the high specific gravity of the cells.

Normally contain calcium carbonate crystals as inclusions. These are in the form of large spherules, one or two of which nearly fill the individual cells. Sulfur globules have not been demonstrated with certainty as yet.

Microaerophilic, but it is uncertain whether hydrogen sulfide is required.

Source: From stems, leaves, etc. of fresh water plants in ponds near Graz, Austria.

Habitat: Fresh water environments containing calcium ions; but it has been found in sulfide-containing as well as in sulfide-free water. In shallow basins and streams in upper layers of the mud.

Note: Another species in this genus is *Macromonas hyalina* (Gicklhorn) Utermöhl and Koppe. (*Pseudomonas hyalina* Gicklhorn, Cent. f. Bakt., II Abt., *50*, 1920, 426; Utermöhl and Koppe, Arch. f. Hydrobiol., Suppl., *5*, 1925, 235.) Similiar to *Macromonas bipunctata.*

APPENDIX TO ORDER CHLAMYDOBACTERIALES

A recently recognized order of filamentous bacteria includes organisms similar in many ways to those included in *Chlamydobacteriales*.

ORDER CARYOPHANALES PESHKOFF.*

(Jour. Gen. Biol., (Russian), *1*, 1940, 611, 616.)

Filamentous or bacillary bacteria of variable size characterized either by the presence of a central body or a ring-like nucleus which frequently takes the form of a disk. These bodies are clearly visible in the living cells. The nuclear elements give a clear-cut Feulgen reaction. The filaments may be enclosed in a sheath. Colorless. The individuals consist of cylindrical cells enclosed in a continuous sheath or they are tube-like coenocytic organisms containing varying numbers of ring or disk-like nuclei separated from each other by alternating protoplasmic segments. These may disintegrate into mononucleate coccoid cells. Gonidia sometimes formed. Found in water and in the intestines of arthropods and vertebrates.

FAMILY I. PONTOTHRICACEAE PESHKOFF.

Jour. Gen. Biol. (Russian), *1*, 1940, 611, 616.)

Long, unbranched filaments which consist of separate cells in a continuous sheath. Multiplication by cell division, homogonia and unicellular gonidia. Resemble the blue green algae but they are non-motile and photosynthetic pigments are lacking. Free living forms.

Genus I. **Pontothrix** *Nadson and Krassilnikow.*

(Comp. rend. Acad. Sci. de U.R.S.S., A, No. 1, 1932, 243–247.)

Characters as for the family.

The type species is *Pontothrix longissima* (Molish) Nadson and Krassilnikow.

1. **Pontothrix longissima** (Molish) Nadson and Krassilnikow. (*Chlamydothrix longissima* Molish, Cent. f. Bakt., II Abt., *33*, 1912, 60; Nadson and Krassilnikow, *loc. cit.*, 243.) Cells in the filaments, 1.5 to 2.0 by 1.0 to 5.0 microns. Filaments 0.5 cm in length. Cells show a central chromatin body. Found on *Zostera marina* in the Bay at Sebastopol on the Black Sea.

FAMILY II. ARTHROMITACEAE PESHKOFF.

(Jour. Gen. Biol. (Russian), *1*, 1940, 611, 616.)

Filaments probably divided into cells although septa (protoplasmic?) disappear during sporulation. Disk-like nuclei alternate with thin protoplasmic segments (septa). Spores form in the distal ends of filaments. Non-motile. The filaments are attached by a spherical body in groups to the intestinal wall of insects, crustaceans and tadpoles.

Genus I. **Arthromitus** *Leidy.*

(Proc. Acad. Nat. Sci., Philadelphia, *4*, 1849, 227.)

Characters as for the family. Although the description is worded somewhat differently, there does not seem to be any essential difference between this and the following genus.

The type species is *Arthromitus cristatus* Leidy.

---

* Arranged by Prof. Michael A. Peshkoff, Institute of Cytology, Acad. of Sci., Moscow, U.S.S.R., April, 1947.

1. **Arthromitus cristatus** Leidy. (Proc. Acad. Nat. Sci., Phila., *4*, 1849, 227 and Jour. Acad. Nat. Sci. Phila., *8*, 1881, 443.) From the intestine of the milliped (*Julus marginatus*) and the termite (*Reticulitermes flavipes*). Filaments delicate, straight or inflected, growing in tufts usually of moderate density, from minute, attached, yellowish rounded or oval bodies. Articuli short, cylindric, uniform, length 2.75 microns, width 0.6 micron, no trace of interior structure. Length of filament 67 to 543 microns, breadth 0.6 micron.

2. **Arthromitus intestinalis** (Valentin) Peshhoff. (*Hygrocrocis intestinalis* Valentin, Report. f. Anat. u. Phys., *1*, 1836, 000; Peshhoff, Jour. Gen. Biol. (Russian), *1*, 1940, 597.) From the intestine of the cockroach (*Blatta orientalis*). Chatton and Perard (Compt. rend. Soc. Biol., Paris, *74*, 1913, 1160) conclude that this species and *Arthromitus cristatus* Leidy are of the same genus although they accept the name *Hygrococis* as having priority. However, the latter is invalid as a bacterial genus because it was given earlier as the name of a genus of algae. See Buchanan, General Systematic Bacteriology, 1925, 183.

3. **Arthromitus nitidus** Leidy. (Smithsonian Contributions to Knowledge, *5*, 1852, 35.) From the intestine of the milliped (*Julus marginatus*).

4. **Arthromitus batrachorum** Collin. (Arch. Zool. Expér. et Gén., *51*, 1913, 63.) From the alimentary tract of toad tadpoles (*Bufo calamita*).

Genus II. Coleomitus *Duboscq and Grassé.*

(*Coleonema* Duboscq and Grassé, Arch. Zool. Expér. et Gén., *68*, 1929, Notes et Revue, 14; not *Coleonema* Bartl. and Wendl., 1924, fam. *Rutaceae*; Duboscq and Grassé, Arch. Zool. Expér. et Gén., *70*, 1930, N. et R., 28.)

Long filaments, divided by partitions. Bacillary elements in basal region. Ovoid or ellipsoidal spores in other parts of filament originating by transformation from these bacillary elements through sporoblasts.

The type species is *Coleomitus pruvoti* Duboscq and Grassé.

1. **Coleomitus pruvoti** (Duboscq and Grassé) Duboscq and Grassé. (*Coleonema pruvoti* Duboscq and Grassé, Arch. Zool. Expér. et Gén., *68*, 1929, Notes et Revue, 14; Arch. Zool. Expér. et Gén., *70*, 1930, N. et R., 28.) In the intestine of a termite (*Kalotermes sp.*) from the Loyalty Islands.

Filaments with hyaline sheath, length variable up to 320 microns, breadth 1.3 microns. Bacillary elements 3 to 4 microns long, also elements up to 6 microns with a chromatic granule or disc in the middle of the body. Spores ellipsoidal 0.8 to 0.9 by 1.7 to 2.0 microns, all containing an excentrically placed granule of volutin.

FAMILY III. OSCILLOSPIRACEAE PESHKOFF.

(Jour. Gen. Biol. (Russian), *1*, 1940, 611, 616.)

Bacillary and filamentous forms. Filaments are most probably partitioned to form narrow cells each containing a central chromatin body (disk-like nucleus). These give a clear Feulgen reaction, and are embedded in hyaline protoplasm. Spores are formed by a fusion of 2–3 protoplasts of neighboring cells. Actively motile. The character of the motion suggests the presence of peritrichous flagella. Parasitic in the intestinal tract of vertebrates.

Genus I. **Oscillospira** *Chatton and Perard.*

(Comp. rend. Soc. Biol., Paris, *65*, 1913, 1159.)

Characters as for the family.

The type species is *Oscillospira guilliermondii* Chatton and Perard.

1. **Oscillospira guilliermondii** Chatton and Perard. (Chatton and Perard, *idem.*) From the intestine of a guinea pig. Spores 2.0 by 4.0 to 5.0 microns (Krassilnikow, Microbiol. Jour. (Russian), *6*, 1928, 249).

FAMILY IV. CARYOPHANACEAE PESHKOFF.

(Jour. Gen. Biol. (Russian), *1*, 1940, 611, 616.)

Large filamentous and bacillary forms. Individuals not divided into cells; they are virtually coenocytic tubular organisms containing alternating ring, horseshoe or disk-like nuclei and protoplasmic segments. Such nuclei are most comparable with single chromosomes reproducing themselves by means of a true endomitosis (Peshkoff, Nature, *154*, 1946, 137). No spores formed. When motile, possess peritrichous flagella. They are found on the mucous membranes of the mouth cavities of man and various animals, and in the alimentary tracts of ruminants.

Genus I. **Caryophanon** *Peshkoff.*
(*Loc. cit.*)

Characters as for the family.

The type species is *Caryophanon latum* Peshkoff.

1. **Caryophanon latum** Peshkoff. (Compt. rend (Doklady) Acad. Sci., U.R.S.S. Nouvelle série, *25*, 1939, 244; Jour. Gen. Biol. (Russian), *1*, 1940, 527; Microbiology (Russian), *15*, 1946, 189.)

Slightly curved rods 3.1 by 15 to 20 microns. Grow on cow manure-extract agar pH 7.8 to 8.0. Also grow on yeast-extract agar at same pH. Aerobic. Isolated from 20 to 30 per cent of samples of fresh cow manure. Non-pathogenic. Isolated at least 20 times in Moscow (U.S.S.R.) and its vicinity by Peshkoff. In 1945 isolated and successfully cultivated in England by Robinow and Pringsheim. Apparently ubiquitous, connected with ruminants. Colonies round, 1 to 2 mm in diameter with slightly undulate margins. Subject to distinct S-R variation. R forms tend to grow in long motile filaments and are much thinner than the plump S individuals. May occur in the form of mononucleate coccoids (especially on yeast-extract agar) and polynucleate bacilli. When grown from old cultures may develop irregular giant forms.

2. **Caryophanon tenue** Peshkoff. (Comp. Rend. (Doklady) Acad. Sci. U. R. S. S., Nouvelle Sér., *25*, 1939, 244; Jour. Gen. Biol. (Russian), *1*, 1940, 597.)

Similar to the above species, but more slender. Diameter 1.5 microns. Grows on cow manure extract agar and yeast-extract agar at pH 7.8 to 8.0. From fresh cow manure.

3. **Caryophanon muelleri** *comb. nov.* (*Simonsiella muelleri* Simons, Cent. f. Bakt., I Abt., Orig., *88*, 1922, 50.) Non-motile. Found on mucous membrane of oral cavity of healthy humans, 3.0 to 4.5 by 10.0 microns.

4. **Caryophanon crasse** *comb. nov.* (*Simonsiella crassa* Simons, *loc. cit.*, 509.) Non-motile. Found on mucous membrane of domestic animals.

5. **Caryophanon filiformis** *comb. nov.* (*Simonsiella filiformis* Simons, *loc. cit.*, 509.) Long filaments from mucous membrane of oral cavity of domestic animals.

ORDER IV. MYXOBACTERIALES JAHN.*

(Kryptogamenflora der Mark Brandenburg, V, Pilze 1, Lief. 2, 1911, 201.)

Synonymy: *Myxobacteriaeae* Thaxter, Bot. Gaz., *17*, 1892, 389; *Myxobactrales* Clements, The genera of fungi. Minneapolis, 1909, 8; *Synbacteriés* Pinoy, Compt. rend. Acad. Sci., Paris, *157*, 1913, 77; *Myxobactericae* Heller, Jour. Bact., *6*, 1921, 521; *Polyangidae* Jahn, Beiträge zur botanischen Protistologie, I, Die Polyangiden, Geb. Borntraeger, Leipzig, 1924; *Myxobacteriae* Stanier and van Niel, Jour. Bact., *42*, 1941, 437.

The name *Myxobacteriaceae*, although having the form of a family designation, was proposed by Thaxter (*loc. cit.*) in an article bearing the title "On the *Myxobacteriaceae*, a new order of *Schizomycetes*." Apparently the first ordinal name was that given by Clements (*loc. cit.*), but does not follow the spelling fixed by the precedent of Thaxter. The revised spelling was given by Jahn as *Myxobacteriales*. Pinoy (*loc. cit.*) suggested *Synbacteriés*. The name *Myxobacterieae* was proposed by Heller (*loc. cit.*) as a class designation, *Bacteria* being regarded as the designation of a phylum. *Polyangidae* is likewise a class designation, Jahn (1924, *loc. cit.*) concluding this group should be coordinate in rank with the *Schizomycetes*. Buchanan (Jour. Bact., *3*, 1918, 541) proposed the name *Myxobacteriales*, not knowing of the previous use of the term. He has therefore at times been incorrectly designated as the author of the name.

It may be argued that a more appropriate ordinal designation might be *Polyangiales*, inasmuch as the generic name *Myxobacter* proposed by Thaxter was soon found to be a synonym of *Polyangium* Link. However, there would seem to be justification of the retention of a name based upon an "ancient generic name" in Rule 21 of the Brussels Code.

The group is herein regarded as an order, though Jahn, and Stanier and van Niel agree in regarding it as a class.

Common or trivial names. The slime bacteria, myxobacteria or polyangids.

Brief characterization of the order. The relatively long, slender, flexible, non-flagellate vegetative cells produce a thin, spreading colony (pseudoplasmodium, swarm). The cells are often arranged in groups of 2 or 3 to a dozen or more, their long axes parallel. The group moves as a unit, by means of a crawling or creeping motion, away from the center of the colony. The moving cells pave the substrate with a thin layer of slime on which they rest.

During sporulation (which occurs in all forms except members of the genus *Cytophaga*) the cells are much shortened, in some cases becoming spherical or coccoid, thick-walled and highly refractile. Fruiting bodies are formed by the species of all families except the *Cytophagaceae* and the genus *Sporocytophaga* of the family *Myxococcaceae*. The fruiting bodies may consist of aggregations of cysts in which the spores (resting cells) are inclosed, or of masses of mucilaginous slime surrounding large numbers of shortened, rod-shaped, or coccoid spores. Fruiting bodies may be sessile or stalked. They are usually pigmented a bright shade of orange, yellow, red or brown, though colorless fruiting bodies, as well as black, have been described.

---

* The section covering the order *Myxobacteriales* was first developed in its present form by Professor R. E. Buchanan, Iowa State College, Ames, Iowa, for the fourth edition of the Manual issued in 1934. It was revised by Professor Buchanan for the fifth edition in 1939. The present review has been carried out by Dr. J. M. Beebe and Professor R. E. Buchanan who had had material assistance from Dr. R. Y. Stanier, April, 1943.

Members of the genus *Sporocytophaga* are not known to produce fruiting bodies as such, but often dense agglomerations of shortened rods or cocci have been noted; these may be interpreted as primitive forms of fruiting bodies.

Physiologically most species show great similarity, preferring substrates rich in cellulosic or other complex carbohydrate materials.

Most of the known species are saprophytic or coprophilic and may be found on dung, in soil, on rotten wood, straw, leaves, etc. They frequently appear to live in close association with various true bacteria and are probably parasitic on them. Many have been cultivated on dung. One species is aquatic and parasitic on an alga, *Cladophora sp.* (Geitler, Arch. f. Prostistenol., *50*, 1924, 67). One is parasitic (?) on lichens and some are halophilic marine forms (Stanier, Jour. Bact., *40*, 1940, 623). Another species is reported as pathogenic for fish (Ordal and Rucker, Proc. Exper. Biol. and Med., *56*, 1944, 15).

Culture media. The myxobacteria are frequently cultured by transferring to dung. For certain species sterilized dung has been reported as less favorable than the unsterilized. Dung decoction agar has often been employed. Among the early investigators, Quehl (Cent. f. Bakt., II, Abt., *16*, 1906, 9) secured slow growth of some species on malt extract-gelatin at 18° to 20°C with digestion of the gelatin. Potato-nutrient agar was reported better than dung agar, while no growth occurred on sterilized potato alone. Peptone was considered necessary; glucose had little effect. Pinoy (Comp. rend. Acad. Sci., Paris, *157*, 1913, 77) claimed that satisfactory development of *Chondromyces crocatus* depended upon the presence of a species of *Micrococcus* in the medium. Kofler (Sitzber. d. k. Akad. Wiss., Wien, Math. Nat. Klasse, 122 Abt., 1913, 845) successfully used a sucrose-peptone agar to which was added potassium and magnesium salts.

Recent evidence indicates that the carbon requirements of these organisms are met satisfactorily by the more complex carbohydrates, and frequently by their products of hydrolysis. Mishustin (Microbiology, Moscow, 7, 1938, 427), Imšenecki and Solntzeva (Microbiology, Moscow, *6*, 1937, 3), Krzemieniewski and Krzemieniewska (Acta Soc. Bot. Pol., *5*, 1927, 102) and others have reported good growth of several species of myxobacteria on cellulose.

Beebe (Jour. Bact., *40*, 1940, 155) claimed several species to be facultative parasites on various true bacteria. Good growth was obtained on suspensions of killed bacterial cells in 1.5 per cent agar. Sniesko, Hitchner and McAllister (Jour. Bact., *41*, 1941, 26) showed the destruction of living bacterial colonies by colonies of myxobacteria.

Temperature range. Most species cultivated in the laboratory show a minimum between 17° and 20°C though some species grow at 10°C. Maximum growth usually occurs at about 35°C and the maximum growth temperature is about 40°C. More normal fruiting bodies are produced at lower temperatures.

The Krzemieniewskis (Acta Soc. Bot. Pol., *5*, 1927, 102) report that the fruiting bodies of *Melittangium boletus*, *Myxococcus virescens*, *Chondrococcus coralloides*, *Archangium gephyra* and *Archangium primigenium* var. *assurgens* first develop, followed by *Polyangium fuscum* and *P. fuscum* var. *velatum*. At 30°C they appear in about 5 to 7 days, at 17° to 20°C in 8 to 12 days, and at 11° to 14°C in 24 to 30 days. Each 10°C rise in temperature approximately halves the time. Other species are slower in developing.

The vegetative rods. The vegetative cells are long, flexuous rods, often 30 times as long as broad. Thaxter noted rods up to 15 microns in length though these appear abnormally long. In general the cells are cylindrical, more rarely tapered or pointed at the ends. Jahn (1924, *loc. cit.*) described spindle-shaped cells. Thaxter (Bot. Gaz., *37*, 1904, 405) believed that a highly elastic wall was present; other authors have

failed to prove it by plasmolytic agents. Jahn states that tinctorial and chemical methods failed to definitely show the presence of a membrane, but that the elasticity of the cells show this clearly. The cells are flexible, not rigid as are ordinary bacteria. Beebe (Jour. Bact., *41*, 1941, 214) reported the presence of a cell membrane in *Myxococcus xanthus*, often made visible with proper staining procedures. The cells frequently show one or more refractive granules. Thaxter also noted nucleus-like granules in the spores of *Myxococcus*, while Bauer (Arch. f. Protistenk., *5*, 1905, 92) reported that during germination of the spores of *Myxococcus* a refractile granule is found at each end of the cell. Badian (Acta Soc. Bot. Pol., *7*, 1930, 55) stated that the cell of *Myxococcus virescens* lacks a true nucleus, but that there is present a basophilic structure probably nuclear in nature. It is dumb-bell-shaped and divides longitudinally in mitosis. In spore formation an autogamy occurs followed by what appears to be a reduction division. All chromatin material was Gram-negative except during reduction; it may be stained by hematoxylin. Beebe noted a condensed mass of nuclear material in the vegetative cells of *Myxococcus xanthus* that divided by constriction prior to each cell fission. Nuclear division is considered to be non-random amitosis. Cell division is by means of constriction at a point near the center and is always complete. The nucleus is stained by gentian violet and by iron-hematoxylin and gives a faintly positive Feulgen reaction. What appears to be an autogamous fusion of chromosomes takes place during sporulation, followed by a nuclear division during germination of the spores. The spores germinate by a process analagous to budding. Vahle (Cent. f. Bakt., II Abt., *25*, 1909, 178) found fat globules and occasional small volutin granules in 3 to 4 day old cultures. Glycogen was not found.

In masses the vegetative rods may be somewhat reddish in color. Thaxter suggested the possibility that the color might be bacteriopurpurin. Treated with concentrated sulfuric acid the pigment gives a blue reaction, hence Jahn (1924, *loc. cit.*) concludes it to be carotin.

Motility of the cells. Baur (*loc. cit.*) states that cells have a power of forward movement at a rate of about 10 microns per minute. No flagella are present. The cells do not "swim." They may bend and are unlike most true bacteria in this respect, though Dobell (Quart. Jour. of Microscop. Science, *56*, 1911, 395 and Arch. f. Protistenkunde, *26*, 1912, 117) describes such flexibility for the giant bacteria (see *Bacillus flexilis*). This is characteristic also of *Beggiatoa*, *Oscillatoria* and *Spirochaeta*.

The cells *en masse* move in a "front," advancing and leaving behind a slime. The cells in general tend to lie on rather than in the slime. The exact mechanism of motion has proved puzzling. Jahn believes the motion to be related to that of forms like *Oscillatoria*, and to be due to excretion of slime from the cell, probably an asymmetrical excretion which pushes the cell along.

The colony. This has been variously termed a swarm, pseudoplasmodium, plasmodium and reproductive communalism. It bears a faintly superficial resemblance to the plasmodium of certain of the slime molds (*Myxomycetes*) but differs in that the true plasmodium is composed of the fused bodies of large numbers of amoeboid cells. The myxobacterial colony is an aggregation of individual rod-shaped, bacterial cells that are not amoeboid. The slime produced by the cells is not protoplasmic, and the colony is not motile but increases in size as the cells move away from the center. Larger numbers of cells are to be found at the margins than on the central portions of the colony; in consequence, fruiting bodies tend to be found in concentric rings on the colony. The cells lie on the surface of the slime which they secrete, not in it.

Thaxter proposed the term "pseudoplasmodium" as a satisfactory descriptive name for the vegetative colony, while Jahn preferred the use of "swarm stage." Inasmuch as the term "colony" in relation to bacterial growth implies large numbers of vegetative cells developing as a unit without regard for size, shape or structure, it is equally suitable. Stanier (Bact. Rev., *6*, 1942, 183) speaks of the condition as "reproductive communalism."

Pigmentation of the fruiting bodies is commonly employed in the differentiation of species. Species that produce colorless cysts and some with black pigment have been reported; in general the fruiting bodies are brightly colored in shades of yellow, red, orange or brown. The color seems to originate in the slime or cyst walls rather than in the encysted cells; its nature is not well understood. The Krzemieniewskis (Bull. Acad. Polon. Sci. Lettres, Classe Sci. Math. Nat., Sér. B, Sci. Nat., I, 1937, 11) noted that the orange-red fruiting bodies of *Sorangium compositum* became gray-brown in strong alkali; the pigment was highly soluble in acetic acid and alcohol and easily soluble in ether and chloroform. It was insoluble in benzol, carbon di-sulfide and petroleum ether. They suggested that it was a carotin derivative rather than true carotin.

Beebe (1941, *loc. cit.*) found that the pigments of *Polyangium fuscum*, *Podangium erectum*, *Myxococcus virescens*, *Chondrococcus blasticus* and *Myxococcus xanthus* gave typical carotin reactions in concentrated sulfuric acid, but were insoluble in chloroform, ether, acetone and methyl and ethyl alcohol. An atypical carotin reaction resulted with hydrochloric and nitric acids. He concluded the pigments to be related to the carotins.

The fruiting bodies. After growth as a vegetative colony the pseudoplasmodium usually forms fruiting bodies which may in the different species be of many shapes and sizes. Differentiation of species, genera and families is based almost entirely upon the character of fruiting body developed. In some cases a stalk is produced, in some not.

In some forms the stalk is delicate and white, consisting of little-changed slime, in other cases it may be stiff and colored. The rods evidently are carried up by the slime which they secrete. In some forms the stalk is simple and short, in others relatively long and branched.

The rods ordinarily associate in more or less definite clumps to form cysts. These cysts may be sessile or stalked. Usually the rods shorten and thicken materially before the cyst ripens. In some forms they shorten so much as to become short ovoid or cylindrical, functioning as spores. They are not endospores such as are found in the genus *Bacillus*.

The cysts may or may not possess a definite membrane produced from slime. Usually the cysts are bright colored, frequently red, orange or yellow. The spores within the cysts when dried retain their vitality for considerable periods of time. Jahn records germination of *Polyangium fuscum* after 5¾ years, of *Myxococcus fulvus* after 8 years.

Methods of isolation. One technic of isolation used by the Krzemieniewskis (1927, *loc. cit.*) was to sieve the fresh soil, place it on blotting paper in petri dishes, and add sterilized rabbit dung. The soil was saturated with water to 70 to 100 per cent, and the plates incubated at 26° to 30°C. After 5 to 10 days fruiting bodies began to appear on the dung. Numerous species were isolated by this method.

Mishustin (*loc. cit.*) employed silica gel plates on the surface of which sterilized filter paper had been placed. Small lumps of soil were placed on the filter paper and the plates incubated for several days at various temperatures. Vegetative myxo-

bacterial colonies developed around the inocula and were purified by transfer to fresh cellulose plates.

Beebe reported a modified Krzemieniewski technic to be satisfactory. Fruiting bodies that had developed on sterilized rabbit dung were transferred to bacterial suspension agar plates. Associated bacteria failed to grow well, but myxobacteria developed rapidly.

The species of the genera *Cytophaga* and *Sporocytophaga* require special technics (Stanier, Bact. Rev., *6*, 1942, 143). The soil forms which decompose cellulose may be enriched with a medium consisting of cellulose (usually in the form of filter paper) and a neutral or slightly alkaline mineral base containing either ammonium or nitrate salts as nitrogen source. For certain species chitin may be substituted for cellulose. Pure cultures may be secured by use of soft agar (1 per cent or less) with finely divided cellulose or with cellulose dextrins (Fuller and Norman, Jour. Bact., *46*, 1943, 281).

Cultivation of organisms. Pure cultures of many species have been grown upon various media and substrates. Sterilized dung, dung decoction agar, nutrient agar, potato and potato agar, sterilized lichens, etc. have all been used. Little study has been made of the food requirements. Recent evidence indicates the utilization of some of the more complex carbohydrates. Imšenecki and Solntzeva (Microbiology, Moscow, *6*, 1937, 3) reported the growth of certain species on cellulose with partial decomposition of that compound. Mishustin (Microbiology, Moscow, *7*, 1938, 427) isolated five species of cellulose-decomposing myxobacteria, cultivating them on a mineral salt-silica gel medium to which filter paper had been added as a source of carbon. Krzemieniewska (Acta. Soc. Bot. Polon., *7*, 1930, 507) grew species of the *Cytophagaceae* on cellophane, while Stapp and Bortels (Cent. f. Bakt., II Abt., *90*, 1934, 28) record the growth of other members of the same family on media containing such carbon sources as mannitol, glucose, sucrose, dextrin, cellotriose and cellobiose. Inorganic nitrogen sources compared favorably with organic, in some cases appearing to be preferable. Stanier (Jour. Bact., *40*, 1940, 623) observed peptone and yeast extract to be the only suitable nitrogen sources for the *Cytophagaceae*, inorganic salts and amino acids failing in this respect. Agar and cellulose were decomposed, while chitin and starch were not utilized. Johnson (Jour. Bact., *24*, 1932, 335) and Benton (Jour. Bact., *29*, 1935, 449) both reported chitinovorous myxobacteria. Beebe (Iowa State Coll. Jour. Sci., *15*, 1941, 319 and *17*, 1943, 227) claimed growth of species of *Polyangium*, *Podangium*, *Chondrococcus* and *Myxococcus* on 1.5 per cent agar with no other nutrients added. Peptone appeared to aid development, while the addition of beef extract had no favorable effect. Moderate growth occurred on a mineral salt-agar medium without the addition of carbon or nitrogen sources. Growth was stimulated by the addition of various complex carbohydrates including cellulose and starch, the latter being hydrolyzed; complete inhibition resulted with pentoses and hexoses. Best growth was reported on a medium composed of dried bacterial cells suspended in 1.5 per cent agar. The suspended cells were lysed by the myxobacteria.

The Krzemieniewskis (Acta Soc. Bot. Pol., *5*, 1927, 102) showed that the optimum hydrogen ion concentrations for growth of different species were found between pH 3.6 and 8.0. Beebe (1941, *loc. cit.*) reported no growth of any species below pH 6.0, while moderate development was noted up to pH 9.0.

Habitat and distribution. Many species have been described from dung. The work of the Krzemieniewskis (Acta Soc. Bot. Pol., *5*, 1927, 102), Mishustin (Microbiology, Moscow, *7*, 1938, 427), Imšenecki and Solntzeva (*loc. cit.*) and others seems to indicate that they occur commonly in soils, particularly soils under cultivation or high in organic materials. Different species appear to be characteristic of various

types of soils. *Polyangium cellulosum* var. *ferrugineum* Mishustin and *Polyangium cellulosum* var. *fuscum* Mishustin (*loc. cit.*) were observed to be common in the black soils of Eastern European Russia, while a similar variety of the same species was reported only from podzol soils. Species of the families *Polyangiaceae*, *Sorangiaceae* and to a lesser degree *Archangiaceae* appear to predominate in Russian and European soils, while the soils of Central and Western United States seem to be more suitable for the growth of the *Myxococcaceae*. Soils of mountainous regions are said to contain fewer numbers of myxobacteria than those of lowland areas.

The distribution of myxobacteria in the soil seems to show a relationship to the hydrogen ion concentration. Some species are found only in neutral or alkaline soils (pH 7.0 to 8.0), others only in acid soils (pH 3.6 to 6.4). Some species show a wide tolerance (pH 3.6 to 8.0).

Relationships of the Myxobacteria. The resemblance of the pseudoplasmodium of the myxobacteria to the plasmodium of the slime molds is as noted above probably to be regarded as without significance, as is also the superficial resemblances of the fruiting bodies of the two groups. Jahn (1924, *loc. cit.*) dismisses the relationship to the *Thiobacteriales* suggested by Thaxter as improbable. Thaxter believed the possession of the red color might show presence of bacteriopurpurin; but Jahn found a carotin reaction which argues against this idea. Jahn insists upon a close relationship to the blue-green algae, particularly because of the mobility of the cells and the creeping motion. He does not believe all *Schizophytae* that do not belong to the *Cyanophyceae* (blue-green algae) should be grouped as bacteria. He believes the myxobacteria to be more closely related to the blue-green algae than to the true bacteria, and creates the class *Polyangidae* to be coordinate with the class *Schizomycetes*. In this he ignores the equal evidence of close relationship of the sulfur bacteria to the *Cyanophyceae*. His argument would lead to the recognition of all the orders of bacteria recognized in this MANUAL as classes. The wisdom of this is not apparent. The *Myxobacteriales* may be regarded as a well-differentiated order of the *Schizomycetes* showing some resemblance to the true bacteria on the one hand and the *Myxophyceae* (*Cyanophyceae*) and *Thiobacteriales* on the other.

Families of the Myxobacteriales. The division of the order *Myxobacteriales* into families has been based, in all classifications proposed, upon morphology. The final demonstration by Stanier (Jour. Bact., *40*, 1940, 636) of the close relationship between species of the genus *Cytophaga* and the myxobacteria led him to propose the recognition of a new family, *Cytophagaceae*.

The principal character differentiating this family from the four previously recognized is the absence of differentiated fruiting bodies. The resting cells are rod-shaped in the genus (*Cytophaga*). In another genus recognized by Stanier (*Sporocytophaga*) the resting cells are spherical. This brings the taxonomist face to face with the problem of deciding whether the presence of fruiting bodies or the spherical shape of the spores should be the primary basis of differentiation. The formation of spherical spores is believed to be of sufficient significance to require the inclusion of all organisms producing such in the family *Myxococcaceae*. *Sporocytophaga*, although it produces no fruiting body, is therefore placed in this family, while those forms which produce neither spherical spores nor fruiting bodies (genus *Cytophaga*) are placed in the new family *Cytophagaceae*.

Krzemieniewska's (Acta Soc. Bot. Pol., 7, 1930, 507 and Arch. Microbiol., 4, 1933, 394) conclusion that two distinct cell shapes appear in the myxobacteria (short, thick rods with ends almost truncate, and long, slender rods almost spindle-shaped in some cases with pointed tips) is supported by Stanier (Bact. Rev., *6*, 1942, 143) as also the

conclusion that the family *Archangiaceae* should be abandoned (Krzemieniewski and Krzemieniewska, Bull. Acad. Pol. Sci. Lettres, Classe Sci. Math. Nat., Sér. B., Sci. Nat., I, 1937, 11–31) and the genera and species redistributed. The validity of the argument is accepted, but the family is retained until a satisfactory revision can be effected. This should be based on a careful comparative study of the species.

Key to the Families of Order **Myxobacteriales.**

I. Neither definite fruiting bodies (cysts) nor spores (microcysts) produced.
Family I. *Cytophagaceae*, p. 1012.

II. Spores (resting cells, microcysts) produced.
- A. Resting cells (spores, microcysts) elongate, not spherical or ellipsoidal. Fruiting bodies (cysts) produced.
  - 1. Fruiting bodies (cysts) not of definite shape; cells heap up to produce mesenteric masses or finger-like (columnar) bodies.
Family II. *Archangiaceae*, p. 1017.
  - 2. Fruiting bodies (cysts) of definite shape.
    - a. Cysts usually angular. Vegetative cells usually thick and short, with blunt, rounded ends.
Family III. *Sorangiaceae*, p. 1021.
    - aa. Cysts usually rounded. Vegetative cells long and thin, sometimes spindle-shaped with pointed ends.
Family IV. *Polyangiaceae*, p. 1025.
- B. Resting cells (spores, microcysts) spherical or ellipsoidal. Fruiting bodies produced except in genus *Sporocytophaga*.
Family V. *Myxococcaceae*, p. 1040.

FAMILY I. CYTOPHAGACEAE STANIER.

(Jour. Bact., *40*, 1940, 630.)

Flexible, sometimes pointed rods, showing creeping motility. No fruiting bodies or spores (microcysts) formed. There is a single genus *Cytophaga*.

Genus I. **Cytophaga** *Winogradsky.*

(Ann. Inst. Pasteur, *43*, 1929, 578.)

Diagnosis: As for family. From Greek *kytos*, hollow place or cell; and *phagein*, to eat, devour.

The type species is *Cytophaga hutchinsonii* Winogradsky.

Key to the species of genus **Cytophaga.**

I. From soil.
  A. Do not utilize starch.
    1. Produce yellow pigment on cellulose.
      1. *Cytophaga hutchinsonii.*
      2. *Cytophaga lutea.*
    2. Produces orange pigment on cellulose.
      3. *Cytophaga aurantiaca.*
    3. Produces pink pigment on cellulose.
      4. *Cytophaga rubra.*
    4. Produces olive-green pigment on cellulose.
      5. *Cytophaga tenuissima.*
  B. Utilize starch.
    1. Produces yellow to orange pigment on starch.
      6. *Cytophaga deprimata.*
    2. Produces cream to pale yellow pigment on starch.
      7. *Cytophaga albogilva.*

II. From sea water.
  A. Dark pigment on cellulose.
      8. *Cytophaga krzemieniewskae.*
  B. No pigment on cellulose.
      9. *Cytophaga diffluens.*
  C. Liquefies agar.
      10. *Cytophaga sensitiva.*

1. **Cytophaga hutchinsonii** Winogradsky. (Winogradsky, Ann. Inst. Pasteur, *43*, 1929, 578; *Cytophaga* strain 8, Jensen, Proc. Linn. Soc. N. S. Wales, *65*, 1940, 547; not *Cytophaga hutchinsoni* Imšenecki and Solntzeva, Bull. Acad. Sci. U.S.S.R., Ser. Biol., No. 6, 1936, 1129.)

Etymology: Named for H. B. Hutchinson.

Rods: Highly flexible, occurring singly, 0.3 to 0.4 microns wide at the center and tapering to both ends. Length 3.0 to 6.0 microns, according to Krzemieniewska (Arch. Mikrobiol., *4*, 1933, 396); 1.8 to 4.0 microns, according to Jensen (*loc. cit.*). May be straight, bent, U-shaped or S-shaped. Stain poorly with ordinary aniline dyes. With Giemsa's or Winogradsky's stain young cells are colored uniformly except for the tips, which remain almost colorless; in older cells there is a concentration of chromatin material at the center. Old cultures show large coccoid cells which are not readily seen. Gram-negative.

Growth on cellulose, cellobiose, cellulose dextrins and glucose. On mineral salts-silica gel plates covered with filter paper, bright yellow glistening mucilaginous patches are produced after a few days. The filter paper in these regions is gradually completely dissolved and the patches become translucent.

Ammonia, nitrate, asparagin, aspartic acid and peptone can serve as sources of nitrogen, according to Jensen (*loc. cit.*).

Strictly aerobic.

Optimum temperature 28° to 30°C.

Source: Isolated from soil.

Habitat: Soil. Decomposes plant residues.

2. **Cytophaga lutea** Winogradsky. (Ann. Inst. Pasteur, *43*, 1939, 599.)

Etymology: Latin *luteus*, yellow.

Dimensions of the cells approximately those of *Cytophaga aurantiaca* (see below) but rather larger and thinner and without marked central swelling. Gram-negative.

Produces a brilliant yellow pigment similar to that of *Cytophaga hutchinsonii*.

This species differs only in size from *Cytophaga hutchinsoni*, and is probably a variety of it.

Source: Isolated from soil.

Habitat: Soil. Decomposes plant residues.

3. **Cytophaga aurantiaca** Winogradsky. (Ann. Inst. Pasteur, *43*, 1929, 597; probably *Mycococcus cytophagus* Bokor, Arch. Microbiol., *1*, 1930, 34.)

Etymology: Modern Latin *aurantiacus*, orange-colored.

Cells 1.0 micron wide at the center by 6 to 8 microns long. Except for size, very similar to those of *Cytophaga hutchinsonii*. Gram-negative.

Produces orange mucilaginous patches on filter paper-silica gel plates. Fibrolysis is very rapid and intense.

Source: Isolated from soil.

Habitat: Soil. Decomposes plant residues.

4. **Cytophaga rubra** Winogradsky. (Ann. Inst. Pasteur, *43*, 1929, 598.)

Etymology: Latin *ruber*, red.

Pointed rods, straight or sometimes slightly bent, occasionally hooked at one end. Length approximately 3 microns. Gram-negative.

Produces diffuse, rapidly-spreading, pink to brick-red patches on filter paper-silica gel plates. Fibrolysis is much slower and less extensive than that caused by *Cytophaga hutchinsonii*.

Source: Isolated from soil.

Habitat: Soil. Decomposes plant residues.

5. **Cytophaga tenuissima** Winogradsky. (Ann. Inst. Pasteur, *43*, 1929, 599; incorrectly spelled *Cytophaga ternissima* in Bergey et al., Manual, 4th ed., 1934, 559.)

Etymology: Latin *tenuissimus*, most tenuous, very slender.

Dimensions of cells not given, but described as being extremely slender. Gram-negative.

Produces mucilaginous, greenish to olive patches on filter paper-silica gel plates.

Source: Isolated from soil.

Habitat: Soil. Decomposes plant residues.

6. **Cytophaga deprimata** Fuller and Norman. (Jour. Bact., *45*, 1943, 566.)

Etymology: Latin *deprimo*, to depress or sink down.

Rods: Long and flexuous with pointed ends, 0.3 to 0.5 by 5.5 to 10 microns, arranged singly. Creeping motility on solid surfaces. Gram-negative.

Growth on starch agar is at first smoky to faint yellow becoming bright yellow later. Colonies are irregular and concave in elevation. The edge spreads indistinguishably into the surrounding medium and shallow depressions develop around the colony. Small colonies give the plate a characteristic pitted appearance.

Growth on cellulose dextrin agar is

milky white. Colonies are depressed in medium.

Gelatin is liquefied in 4 days.

Glucose, lactose, maltose, sucrose, pectin, starch, cellulose dextrin and hemicellulose are utilized. Very scant growth on cellulose may be found on first isolation.

Yeast extract, ammonium nitrate and peptone are suitable nitrogen sources.

Indole not formed.

Nitrites not produced from nitrates.

No visible change in litmus milk.

Highly aerobic.

Optimum temperature 25° to 30°C.

Source: Isolated from soil.

Habitat: Soil. Decomposes organic matter.

7. **Cytophaga albogilva** Fuller and Norman. (Jour. Bact., *45*, 1943, 566.)

Etymology: Latin *albus*, white, and *gilvus*, pale yellow.

Long flexuous rods with pointed ends, 0.3 to 0.5 by 4.5 to 7.5 microns, arranged singly. Creeping motility on solid surfaces. Gram-negative.

Growth on starch agar is cream to pale yellow. Colonies are small, concave, and irregulary round. Edge is entire and irregular.

Growth on cellulose dextrin agar is restricted. Colonies are pin-point, milky white in color, round and concave.

Gelatin is liquefied in 7 days.

Glucose, galactose, lactose, maltose, sucrose, gum arabic, pectin, starch, cellulose dextrin and hemicellulose are utilized. Very scant growth on cellulose may be found on first isolation.

Ammonia, nitrate and peptone are suitable nitrogen sources.

Indole not formed.

Nitrites not produced from nitrates.

No visible change in litmus milk.

Highly aerobic.

Optimum temperature 22° to 30°C.

Source: Isolated from soil.

Habitat: Soil. Decomposes organic matter.

8. **Cytophaga krzemieniewskae** Stanier. (Incorrectly spelled *Cytophaga krzemieniewskii* in Stanier, Jour. Bact., *40*, 1940, 623; Jour. Bact., *42*, 1941, 532.)

Etymology: Named for H. Krzemieniewska.

Long, flexible rods, usually of even width with blunt ends, occasionally somewhat pointed and spindle-shaped, 0.5 to 1.5 by 5 to 20 microns. Star-shaped aggregates occur in liquid media. Creeping motility on solid surfaces, non-motile in liquids.

Growth on a sea water-peptone agar plate begins as a smooth, thin, pale pink, rapidly spreading swarm. After a few days, the older portions of the swarm assume a warty appearance due to the accumulation of cells in drop-like masses, resembling immature fruiting bodies but always containing normal vegetative cells. A diffusible brown to black pigment which masks the pink color of the swarm is produced after about a week. Agar is rapidly decomposed, and ultimately liquefaction becomes almost complete.

Sea water-gelatin stab: Liquefaction.

Growth in liquid media is turbid and silky with a pink sediment; the medium turns dark brown or black after 1 or 2 weeks.

Xylose, glucose, galactose, lactose, maltose, cellobiose, cellulose, alginic acid, agar and starch are utilized, but not arabinose, sucrose and chitin.

Yeast extract and peptone are the only suitable nitrogen sources known.

Weakly catalase positive.

Indole not formed.

Nitrites produced from nitrates.

Hydrogen sulfide not produced.

Salt concentration range: 1.5 to 5.0 per cent.

Strictly aerobic.

Optimum temperature 22° to 25°C.

Source: Isolated from sea water.

Habitat: Sea water. Probably on decaying marine vegetation.

9. **Cytophaga diffluens** Stanier. (Jour. Bact., *40*, 1940, 623; Jour. Bact., *42*, 1941, 546.)

Etymology: Latin *diffluens*, spreading, flowing away.

Pointed, sometimes spindle-shaped, flexible rods, 0.5 to 1.5 by 4 to 10 microns. In old cultures involution forms consisting of long, twisted, thin threads are found. Star-shaped aggregates of cells occur in liquid media. Creeping motility on solid surfaces, non-motile in liquids.

Growth on a sea water-peptone agar plate begins as a thin, pink, rapidly spreading swarm which often covers the entire surface in a few days. The swarm gradually increases in thickness and develops an irregular, beaten-copper surface due to the liquefaction of the underlying agar. After 4 to 5 days the color becomes orange. Liquefaction of the agar is ultimately almost complete.

Sea water-gelatin stab: Rapid liquefaction.

Growth in liquid media is turbid, often with suspended floccules and a heavy pellicle.

Xylose, glucose, galactose, lactose, maltose, cellobiose, cellulose, agar and alginic acid are utilized, but not arabinose, sucrose, chitin or starch.

Yeast extract and peptone are the only suitable nitrogen sources known.

Weakly catalase positive.

Indole not formed.

Nitrites produced from nitrates.

Hydrogen sulfide not produced.

Salt concentration range: 1.5 to 5.0 per cent.

Slightly aerobic.

Optimum temperature 22° to 25°C.

Source: Isolated from sea water.

Habitat: Sea water. Probably on decaying marine vegetation.

10. **Cytophaga sensitiva** Humm. (Duke Univ. Marine Lab., North Carolina, Bull. 3, 1946, 64.) Etyomology: Latin *sensus*, to perceive.

Cells long, slender, flexous rods. Apparently not flagellated, 0.8 to 1.0 by 7.0 to 20 microns. Cell ends not tapered or only slightly so. Gram-negative. Cells exhibit creeping motility on agar with ability to reverse direction of movement without turning. Bending movements occur in liquid media.

Colonies light orange, thin and shining. Irregular margin. Outer part composed of a single layer of cells, spreading rapidly, the center somewhat thicker and more or less opaque, sunken in the agar. Agar liquefied. Single colony may nearly cover the surface of the agar in the Petri dish within one week; center of colony sinks to the bottom of the dish and may develop vertical sides. Usually the colony begins to die after a week or ten days from the center outward, as shown by loss of pigment. Apparently no water-soluble pigment is produced. Colony 18 mm in diameter and gelase field 25 mm in diameter after three days on agar containing 0.8 per cent potassium nitrate and 0.8 per cent peptone (iodine stain).

Gelatin: No growth.

Milk: No growht.

Nitrate apparently not produced from nitrate (agar medium).

Optimum nitrate concentration of medium appeared to be 0.5 per cent. Fair growth on sea water plus agar only, and on agar containing 1.0 per cent potassium nitrate. Slight growth on 2.0 per cent nitrate agar.

Optimum peptone concentration appeared to be about 0.1 per cent; growth inhibited by concentrations of peptone exceeding 0.4 per cent.

No growth on agar media containing any one of the following substances in a concentration of 0.2 per cent glucose, starch, ammonium sulfate. The basal medium, however, supported excellent growth.

Repeated efforts were made to obtain a pure culture by streaking plates and by pouring plates. These were finally suc-

cessful by the use of an agar medium that contained 0.1 per cent peptone, 0.05 per cent beef extract, 0.05 per cent glucose, and traces of yeast extract and ferric phosphate. Good growth on broth of this composition was also obtained. Apparently the yeast extract supplied necessary growth substances.

Source: Isolated September 19, 1945 from a mixed culture with *Pseudomonas corallina*, by streaking a piece of *Dictyota dichotoma* on agar containing 0.2 per cent potassium nitrate.

Habitat: From seaweed. Beaufort, North Carolina.

Appendix: Stapp and Bortels (Cent. f. Bakt., II Abt., *90*, 1934, 28) described four new obligate cellulose-decomposing species: *Cytophaga silvestris*, *Cytophaga anularis*, *Cytophaga flavicula* and *Cytophaga crocea*. The differences between them are small and, while it is impossible to make positive identifications on the basis of present knowledge, they seem to be very similar to *Cytophaga hutchinsonii*. In the absence of comparative pure culture studies on the obligate cellulose-decomposing members of the genus, the proper delimination of species is not possible. Their inclusion in keys must await additional information.

FAMILY II. ARCHANGIACEAE JAHN.

(Beiträge zur botan. Protistologie, I. Die Polyangiden. Geb. Borntraeger, Leipzig, 1924.)

In the organisms belonging to this family the swarm (pseudoplasmodium) produces irregular swollen or twisted fruiting bodies, or develops columnar or finger-like growths, usually without a definitely differentiated membrane.

Key to the genera of family **Archangiaceae.**

I. Fruiting body depressed, usually irregularly delimited, the interior usually consisting of swollen or intestine-like twisted or inter-twined masses, whose windings may be constricted or may jut out (project) as free ends.

Genus I. *Archangium*, p. 1017.

II. Fruiting body consists of single (separate) columnar or finger-like structures arising from the substrate.

Genus II. *Stelangium*, p. 1020.

Genus I. **Archangium** *Jahn.*

(Jahn, Beiträge zur botan. Protistologie, I. Die Polyangiden. Geb. Borntraeger, Leipzig, 1924, 67; *Ophiocystia* Enderlein, Bermerkungen zur Systematik der Chondromyciden, Berlin, 1924, 6 pp.)

Etymology: Greek *arche*, primitive, and *angion*, vessel (according to Jahn, this genus is the most primitive).

The mass of shortened rods embedded in slime forms a pad-shaped or more rounded, superficially swollen or tuberous fruiting body, even with horny divisions. The fruiting body has no membrane. In the interior can be seen a mass resembling coiled intestines. The windings of this coil may be uniform, or irregularly jointed, free or stuck together; the ends may be extended and horny. Instead of a membrane there may be loosely enveloping slime.

The type species is *Archangium gephyra* Jahn.

Key to the species of genus **Archangium.**

I. No slimy capsules.
  A. Fruiting body usually wound, irregularly constricted, sometimes swollen and vesicular, appressed.
    1. Fruiting body red.
      a. The shortened rods 2.5 to 3 microns.
        1. *Archangium gephyra.*
      aa. The shortened rods 4 to 6 microns.
        2. *Archangium primigenium.*
    2. Fruiting body yellow.
        3. *Archangium flavum.*
  B. Tube usually uniformly thick, loosely wound, often branched.
        4. *Archangium serpens.*

II. Fruiting body consisting of a reddish coiled tube, embedded in yellow slime.
        5. *Archangium thaxteri.*

1. **Archangium gephyra** Jahn. (*Chondromyces serpens* Quehl, Cent. f. Bakt., II Abt., *16*, 1906, 16; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 67.)

Etymology: Greek *gephyra*, a bridge. So named because a transition form between the *Archangiaceae* and the *Myxococcaceae*.

Swarm stage (pseudoplasmodium): Grows easily in manure decoction, forming a pseudoplasmodium and ring of fruiting bodies. The vegetative rods are about 10 microns long, 0.5 micron in diameter.

Fruiting bodies: Up to 1 mm in diameter, of irregular form and with swollen or padded surface. Average sized fruiting bodies are a reddish flesh color by reflected light; smaller fruiting bodies, a light rose. On a dark background large fruiting bodies when fresh appear bluish violet. By transmitted light the fruiting bodies appear yellowish to light red. Upon addition of alcohol or when heated in glycerine, they lose the color quickly and appear gray or colorless.

The inner structures are for the most part a mesenteric mass of tubes 40 to 60 microns wide, without any membrane, and without any enclosing slime. The convolutions are often pressed together. On the inside of these tubes there appears definitely a septation by straight or slightly arched cross walls which, however, do not always cut entirely through the spore masses from one side of the tube to the other. Upon pressure, the fruiting body breaks up into a number of small fragments about 15 to 30 microns in diameter. Within these fragments the shortened rods lie parallel and in bundles.

The rods in the fruiting bodies are so shortened that they resemble the spores of the *Myxococcaceae*. The spores are 2.5 to 2.8 microns long and about 1.4 microns wide. Often they are somewhat bent so that they appear to be bean-shaped. In the smooth, transparent tips of fruiting bodies they stand closely parallel to each other, so that in transmitted light one sees only their cross section and is at first led to believe that he is dealing with one of the *Myxococcaceae*.

Source and habitat: Found frequently in the region of Berlin on the dung of deer, rabbits, and hare, once also on old decaying lichens. Easily overlooked on account of its usual bluish color. According to Krzemieniewski (1927) the most common of myxobacteria in the soils of Poland. Isolated on rabbit dung.

Illustrations: Quehl (*loc. cit.*) Pl. 1, Fig. 7. Jahn (1924, *loc. cit.*) Pl. 1, Fig. 5. Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, Pl. III, Figs. 25–26.

2. **Archangium primigenium** (Quehl) Jahn. (*Polyangium primigenium* Quehl, Cent. f. Bakt., II Abt., *16*, 1906, 16; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924.)

Etymology: Latin, *primigenius*, primitive, referring to the simple and primitive character of the fruiting body.

Swarm stage (pseudoplasmodium): In manure decoction cysts germinate readily. Vegetative rods 4 to 8 microns in length.

Fruiting bodies: Up to 1 mm in diameter, sometimes larger, with irregularly padded swollen surface; when fresh a lively red color which is quite prominent especially against a dark background; when dried, dark red. In transmitted light flesh red to yellowish red. In alcohol and upon heating it is quickly bleached.

In transmitted light one sees that the fruiting body is made up of numerous intestine-like convolutions closely appressed, not however, always definitely delimited. These tubes usually have a diameter of from 70 to 90 microns, often constricted and attenuated. No membrane is present. The rods in the fruiting bodies are about 4 microns long and 0.8 micron wide. Upon pressure on the fruiting bodies, the rods remain together in small fragments of various sizes.

2a. *Archangium primigenium* var.

assurgens Jahn. (Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, *5*, 1924, 69; *Archangium assurgens* Krzemieniewski, Acta Soc. Bot. Poloniae, 1927, 95.)

Etymology: Latin *assurgens*, rising up.

Size and color of the fruiting body as in the species, likewise the inner structure, size and arrangement of the rods. However, the tubules which together constitute the fruiting bodies are more or less free at their ends and stand up from the substrate. Their diameter is somewhat less (about 45 microns), they are often convoluted so that they many times appear to be constricted (like pearls).

Pronounced races of the species and of the variety are so different in habits that they may be regarded as distinct species. Jahn believes the presence of intermediate strains makes a separation difficult.

Source and habitat: According to Jahn, *Archangium primigenium* is not particularly common. It is usually found on rabbit dung, sometimes.on roe dung. The variety *assurgens* is relatively rare (found three times on rabbit dung) Kofler (1930) on rabbit dung, Vienna. Very rare in Polish soils according to Krzemieniewski (1927).

Illustrations: Quehl, Cent. f. Bakt., II Abt., *16*, 1906, 16, Pl. 1, Fig. 5; Jahn, Kryptogamenflora d. Mark Brandenburg, V, Pilze I, Lief. 2, 1911, 201, Pl. 1, Fig. 5; Jahn (1924, *loc. cit.*) Pl. 1, Fig. 4, also Fig. G, page 37; Krzemieniewski (1926, *loc. cit.*) Pl. II, Fig. 23; (1927, *loc. cit.*) Pl. IV, Fig. 3. var. *assurgens*, Pl. IV, Fig. 1 and 2.

3. **Archangium flavum** (Kofler) Jahn. (*Polyangium flavum* Kofler, Sitzber. d. Kais. Akad. Wiss. Wien. Math.-Nat. Klasse, 122 Abt., 1913, 864; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 71.)

Etymology: Latin *flavus*, golden or reddish-yellow.

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: About 0.5 mm in diameter, yellow, spherical or oval, with humped or padded surface. The mass of cells quite homogeneous, upon pressure under cover glass single sections tend to adhere. No membrane, though the rods are so tightly linked that when cautiously placed under a cover glass, the form of the fruiting body is retained. Rods 2 to 4 microns.

Source and habitat: Kofler (1924) on hare dung found in Danube meadows. Reported as frequent in Polish soils by Krzemieniewski (1926, 1927).

Illustrations: Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, Pl. II, Fig. 24. (1927), Pl. IV, Fig. 4, 5 and 6.

4. **Archangium serpens** (Thaxter) Jahn. (*Chondromyces serpens* Thaxter, Bot. Gaz., *17*, 1892, 403; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 72.)

Etymology: Latin *serpens*, creeping.

Swarm stage (pseudoplasmodium): Rods cylindrical, 0.6 by 5 to 7 microns. Cultures on agar develop convoluted form.

Fruiting body: About 1 mm in diameter, recumbent, consisting of numerous loosely intertwined cysts, confluent in an anastomosing coil, flesh-colored, when dry dark red, 50 microns in diameter, bent, occasionally somewhat broadened or constricted, branched.

Source and habitat: Thaxter, Bot. Gaz., *17*, 1892, 389. On decaying lichens. Cambridge, Mass.

Illustrations: Thaxter (*loc. cit.*), Pl. 24, Fig. 24.

5. **Archangium thaxteri** Jahn. (Beiträge zur botanischen Protistologie. I.

Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 71.)

Etymology: Named for Dr. Roland Thaxter.

Swarm stage (pseudoplasmodium): Vegetative stages not observed. Either no germination or prompt cessation of growth on dung extract. May be transferred on dung.

Fruiting body: Usually 0.25 to 0.5 mm, occasionally 0.75 mm in diameter. Irregularly rounded, superficially sulfur yellow. Upon pressure numerous reddish convoluted tubules are observed embedded in a yellow slime. The average diameter of the tubules is about 50 microns. No membrane surrounds the tubes. They contain the shortened rods. The fruiting body is bleached by alcohol or heat, becoming yellowish. Enveloping slime is variable. In well developed specimens the slime forms a stalk, giving the whole the appearance of a morel. In small specimens the rods are embedded in the slime. The fruiting bodies stand loosely separated on surface of dung, never in large groups. Shortened rods (spores) 0.5 micron by 3 microns, very slender.

Source and habitat: According to Jahn rare, on rabbit dung. Races with well developed stalks even less common.

Illustrations: Jahn (*loc. cit.*), Pl. 1, Fig. 1 and 2. Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, Pl. II, Fig. 27.

Genus II. **Stelangium** *Jahn.*

(Kryptogamenflora der Mark Brandenburg, V, Pilze I, Lief. 2, 1911, 205.)

Etymology: Greek *stele*, pillar or column and *angion*, vessel.

Diagnosis: Fruiting bodies are columnar or finger-like, sometimes forked, without definite stalk, standing upright on the substrate.

The type species is *Stelangium muscorum* (Thaxter) Jahn.

1. **Stelangium muscorum** (Thaxter) Jahn. (*Chondromyces muscorum* Thaxter, Bot. Gaz., *37*, 1904, 411; Jahn, Kryptogamenflora der Mark Brandenburg, V, Pilze I, Lief. 2, 1911, 205.)

Etymology: Latin *muscus*, moss.

Swarm stage (pseudoplasmodium): Not described.

Fruiting body: Bright yellow-orange, 90 to 300 microns long, 10 to 50 microns wide, without differentiated stalk, simple or rarely furcate, upright, elongate, compact or slender, narrowed at tip. Rods (spores) 1 to 1.3 by 4 to 6 microns.

Source and habitat: According to Thaxter (*loc. cit.*) on liverworts on living beech trunks in Indiana.

Illustrations: Thaxter (*loc. cit.*) Pl. 27, Figs. 16–18.

FAMILY III. SORANGIACEAE JAHN.

(Beiträge zur botan. Protistologie. I. Die Polyangiden. Geb. Borntraeger, Leipzig, 1924, 73.)

Diagnosis: The shortened rods of the fruiting body lie in angular, usually relatively small cysts of definite polygonal shape. Often many of these cysts are surrounded by a common membrane. The primary cyst may be differentiated from the angular or secondary cysts. No stalked forms are known.

Genus I. **Sorangium** *Jahn.*

(Jahn, Beiträge z. botan. Protistologie. I. Die Polyangiden. Geb. Borntraeger, Leipzig, 1924, 73; *Cystoecemia* Enderlein, Bemerkungen z. Systematik d. Chondromyciden, Berlin, 1924, 73.)

Etymology: Greek *soros*, heap and *angion*, vessel.

Diagnosis: As for the family. The cysts are united into rounded fruiting bodies. Eight species have been allocated to this genus.

The type species is *Sorangium schroeteri* Jahn.

Key to the species of Genus **Sorangium.**

I. Fruiting bodies not black when ripe.
  A. Primary cysts absent; fruiting body shows only angular, spherical or oval small cysts.
    1. Cysts angular.
      a. Fruiting body very small (50 to 80 microns), often irregularly cerebriform; the angular cysts often completely separated from each other, and about 13 microns in diameter.
        1. *Sorangium schroeteri.*
      aa. Fruiting body composed of many small cysts.
        b. Cysts orange-red in color; over 5.0 microns in diameter.
          2. *Sorangium sorediatum.*
        bb. Rusty brown color; cysts less than 3.5 microns in diameter.
          3. *Sorangium cellulosum.*
    2. Cysts spherical or oval.
      4. *Sorangium spumosum.*
  B. Both primary and secondary cysts present.
    1. Primary cysts small and numerous, about 20 microns, with definite membrane and few angular secondary cysts.
      5. *Sorangium septatum.*
    2. Primary cysts large, with delicate, often indefinite, membrane.
      6. *Sorangium compositum.*
II. Fruiting bodies black or brownish-black when ripe.
  A. Primary cysts generally not formed.
    7. *Sorangium nigrum.*
  B. Primary cysts generally formed.
    8. *Sorangium nigrescens.*

1. **Sorangium schroeteri** Jahn. (Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden. Geb. Borntraeger, Leipzig, 1924, 73; regarded as a synonym

of *Sorangium compositum* by Krzemieniewski, Acta Soc. Bot. Poloniae, *5*, 1927, 96.)

Etymology: Named for Julius Schroeter (1837–1894).

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: Very small, circular, swollen, often kidney-shaped with brain-like convolutions, usually 60 microns (occasionally 120 microns) in diameter, bright orange-red. Surrounded by a delicate slime membrane about 0.7 micron thick, apparent only with high magnifications. Divided secondarily into angular cysts, by sutures extending inward which divide the mass regularly into well delimited portions, many angled, usually about 12 microns in diameter, and in other places into areas less well delimited and about 14 microns in diameter. Resembles gelatin which has dried in a sheet and cracked into regular areas. Rods in cysts 5 microns long. Cysts sometimes occur together in large numbers, covering an area to 0.5 mm.

Source and habitat: Found by Jahn (*loc. cit.*) five times on rabbit dung in environs of Berlin.

Illustrations: Jahn (1924, *loc. cit.*), Pl. 2, Fig. 22.

2. **Sorangium sorediatum** (Thaxter) Jahn. (*Polyangium sorediatum* Thaxter, Bot. Gaz., *37*, 1904, 414; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 73.)

Etymology: From Greek, *soros*, heap, probably through the botanical term soredium, one type of reproductive body in the lichen, and sorediate, with surface patches like soredia.

Swarm stage (pseudoplasmodium): Rods 0.8 by 3 to 5 microns. Attempts to cultivate have failed.

Fruiting body: Orange-red, irregularly lobed, consisting of a compact mass of small angular cysts. Average size of cysts 6 to 7 microns, smallest 3 microns, with thick and sharply defined edges. Rods 0.8 by 3 to 5 microns. The Krzemieniewskis (1927, *loc. cit.*, 96) have described a variety, *Sorangium sorediatum* var. *macrocystum*, consisting of cysts 6 to 14 by 7 to 16 microns, about twice as large as in the type.

Source and habitat: Reported once by Thaxter (*loc. cit.*) on rabbit dung from South Carolina. Krzemieniewski (1927, *loc. cit.*) common in Polish soils.

Illustrations: Thaxter (*loc. cit.*) Pl. 27, Figs. 22–24. Quehl, Cent. f. Bakt., II Abt., *16*, 1906, 9, Pl. 1, Fig. 2. Jahn, Kryptogamen-flora d. Mark Brandenburg, V, Pilze I, Lief. 2, 1911, 202, Fig. 1. Krzemieniewski, Acta Soc. Bot. Pol., *4*, 1926, Pl. IV, Figs. 39–41. (1927, *loc. cit.*) Pl. V, Fig. 17, var. *macrocystum* Fig. 18.

3. **Sorangium cellulosum** Imšenecki and Solntzeva. (Microbiology, Moscow, *6*, 1937, 7.)

Etymology: Modern Latin *cellulosum*, cellulose.

Fruiting body: Mature fruiting body rusty brown, 400 to 500 microns in diameter, sessile on layer of partially dried slime. No outer wall or limiting membrane. Composed of numerous cysts, irregular in shape, 1.6 to 3.2 microns in diameter, each containing less than ten shortened rods. No discernable cyst wall or membrane.

Spores: 0.3 by 1.5 to 2.0 microns (no other data).

Vegetative cells: Flexible, rod-shaped cells with rounded ends, occurring singly; no flagella but motile by means of a crawling motion; 0.4 to 0.6 by 2.2 to 4.5 microns.

Vegetative colony: No data.

Physiology: Good growth on starch, cellulose. Decompose up to 24 per cent cellulose in ten days, but does not form fruiting bodies. Very poor growth on arabinose with formation of many involution forms including very much elongated

cells. Fail to grow on nutrient agar, washed agar, potato, carrot, milk.

Source: Isolated from soil.

Habitat: Soil. Decomposes organic matter.

4. **Sorangium spumosum** Krzemieniewski and Krzemienewska. (Acta Soc. Bot. Poloniae, *5*, 1927, 97.)

Etymology: Latin *spumosus*, frothy or foamy.

Swarm stage (pseudoplasmodium): Rods 0.7 to 0.9 by 2.6 to 5.2 microns.

Fruiting bodies: Consist of numerous cysts, spherical or oval, not surrounded by a common membrane, but united into bodies embedded in slime. Often in double or single rows. Cyst walls colorless, or slightly brownish, transparent, so that the characteristic arrangement of the rods may be seen within. Cysts 8 to 26 by 7 to 20 microns.

Source and habitat: Krzemieniewski (1927, *loc. cit.*) from Polish soil, isolated on rabbit dung.

Illustrations: Krzemieniewski (1927, *loc. cit.*) Pl. V, Fig. 19.

5. **Sorangium septatum** (Thaxter) Jahn. (*Polyangium septatum* Thaxter, Bot. Gaz., *37*, 1904, 412; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 75.)

Etymology: Latin *saeptatus*, fenced, *i.e.*, divided by walls.

Swarm stage (pseudoplasmodium): Rods 0.8 to 1 by 3 to 5 microns.

Fruiting bodies: Yellowish-orange. When dried, dark orange-red, 50 microns to more than 100 microns in diameter, cysts rounded or ovoid, angular or cylindrical, inner portion of the envelope divided into a variable number of secondary cysts. Cysts 18 to 22 by 12 to 22 microns in diameter. Secondary cysts 10 to 12 microns. The Krzemieniewskis (1927, *loc. cit.*, 96) recognize a variety, *Sorangium septatum* var. *microcystum*, which has secondary cysts with dimensions 4 to 10 by 3 to 8 microns.

Source and habitat: Collected twice (Thaxter, Bot. Gaz., *37*, 1904, 412) on horse dung in Cambridge, Mass. Reported by Krzemieniewski (Acta Soc. Bot. Poloniae, *5*, 1927) as common in Polish soil.

Illustrations: Thaxter (*loc. cit.*) Pl. 27, Figs. 25–28. Jahn, Kryptogamen-flora d. Mark Brandenburg, V, Pilze I. Lief 2, 1911, 202, Fig. 2. Krzemieniewski, Acta Soc. Bot. Pol., *4*, 1926, Pl. 27, Figs. 27–38; *ibid.*, 1927, Pl. V, Fig. 15, var. *microcystum*, Fig. 16.

6. **Sorangium compositum** (Thaxter) Jahn. (*Polyangium compositum* Thaxter, Bot. Gaz., *37*, 1904, 413; Jahn, Beiträge zur botanische Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 74; *Polyangium sorediatum* Quehl, Cent. f. Bakt., II Abt., *16*, 1906, 17; not *Polyangium sorediatum* Thaxter, *ibid.*)

Etymology: Latin *compositus*, compound.

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: Dull yellowish-orange changing to dark red on drying. Rounded, small, 0.5 to 1 mm, usually as a whole or even in larger clumps surrounded by a delicate and evanescent membrane. In large fruiting bodies the cysts are bound together in balls 70 to 90 microns in diameter by a delicate membrane. The balls readily fall apart. Secondary cysts are angular, 7 by 11 microns, surrounded by a delicate orange-red membrane, about 0.4 micron in thickness. Length of rods in the cysts 5 microns.

Source and habitat: Thaxter (*loc. cit.*) rabbit dung, South Carolina. Jahn (1904, *loc. cit.*) found it four times on rabbit dung near Berlin, and twice on hare dung in Oberharg. Common in soils of Poland according to Krzemieniewski (1927, *loc. cit.*).

Illustrations: Thaxter (*loc. cit.*) Pl. 27, Figs. 29-30. Jahn (1924, *loc. cit.*) Pl. I, Fig. 6. Krzemieniewski, Acta Soc. Bot. Pol., *4*, 1926, Pl. III, Figs. 32-36; *ibid.*, 1927, *5*, Pl. IV, Figs. 7, 8, 9, 10, 11, 12; Pl. V, Figs. 13, 14; Pl. VI, Fig. 36.

7. **Sorangium nigrum** Krzemieniewski. (Bull. Int. l'Acad. Pol. Sci. et Lettres, Classe Sci. Math. et Nat., Sér. B, *15*, 1937.)

Etymology: Latin *niger*, black.

Fruiting body: Primary cysts generally not formed; when observed, appeared as smoke-colored slime envelope surrounding clumps of a few cysts. Secondary cysts usually arranged in rows within cellulose fibers, the material of the fiber forming a common sheath. Each individual cyst inclosed by a cyst wall, clearly differentiated from the tubular-shaped cellulose fibers. Cysts measure 9 to 16 by 9 to 23 microns; average 10 by 18 microns. Cyst wall moderately thick, colorless, transparent, becoming light brown with age, and finally black.

Spores: No data.

Vegetative cells: 1.1 to 1.3 by 2.5 to 5.5 microns.

Vegetative colony: Young colonies dead black in color. On filter paper a bright orange margin is noted, the vegetative cells of which cover the cellulose fibers. On cotton cloth the margin is bright dirty-yellow, tinged with pink. Under low power magnification, center of the colony appears similar to matted fungal hyphae, due to characteristic compact accumulation of cysts and cellulose fibers.

Physiology: Cellulose fibers become swollen by the action of this organism, and become gray-brown with a violet tinge. Fibers lose the properties of cellulose and give no characteristic reactions.

Source: Isolated from soil.

Habitat: Soil. Decomposes cellulose fibers.

Illustrations: Krzemieniewski (*loc. cit.*) Plate IV, Figs. 22-26.

8. **Sorangium nigrescens** Krzemieniewski. (Bull. Int. l'Acad. Pol. Sci. et Lettres, Classe Sci. Math. et Nat., Sér. B, *15*, 1937.)

Etymology: Latin *nigrescens*, becoming dark or black.

Fruiting body: Primary cysts vary in size up to 200 microns in diameter, irregular in shape and inclosed in a colorless slime envelope. Formed by an accumulation of secondary cysts. Secondary cysts at first colorless, transparent, later becoming brownish with a limiting membrane; the young cysts appear dirty-yellow, the older ones grayish-brown to black. Color originates not only from the brownish cyst wall but from the gray mass of encysted cells. Secondary cysts measure 5 to 12 by 6 to 15 microns; average 6 by 10 microns. On filter paper not only well-formed primary cysts are formed, but also free secondary cysts are noted embedded in the slime of the colony.

Spores: No data.

Vegetative cells: 1.2 to 1.4 by 2.5 to 6.4 microns. Younger cells somewhat shorter.

Vegetative colony: Mass of dark fruiting bodies develops at center of colony on filter paper; margin grayish-yellow. Cellulose fibers covered with vegetative cells on outside, and contain many cells within.

Physiology: Destroys cellulose. Cultivated six years with cellulose as carbon source.

Source: Isolated from sandy soil in pine woods in Ciemianka (?).

Habitat: Soil. Decomposes cellulose fibers.

Illustrations: Krzemieniewski (*loc. cit.*) Plate III, Figs. 17-21.

FAMILY IV. POLYANGIACEAE JAHN

(Beiträge zur botan. Protistologie. I. Die Polyangiden. Geb. Borntraeger, Leipzig, 1924.)

Diagnosis: In the fruiting bodies the more or less shortened rods lie in rounded cysts of definite form. The well-defined wall is composed of hardened slime, and is yellow, red or brownish. The cysts may be united by a definitely visible slime membrane, the remnant of the vegetative slime, or they may be tightly appressed and cemented by the scarcely visible remnants of the slime, or they may develop singly or in numbers on a stalk. In the more highly developed forms the stalk branches and carries the cysts at the tips of the branches.

Key to the genera of family **Polyangiaceae.**

I. Cysts rounded, not stalked, usually many (one in *Polyangium simplex*) lying loosely in a slime membrane or closely appressed.
   Genus I. *Polyangium*, p. 1025.

II. Cysts not as in I.
   A. Cysts pointed at the apex, often completely concrescent, and united to large disks or spheres.
      Genus II. *Synangium*, p. 1032.
   B. Cysts free, single or many on a stalk.
      1. Cysts forming a disk, flattened dorsoventrally, like the cap of a *Boletus*, on a white stalk.
         Genus III. *Melittangium*, p. 1033.
      2. Cysts not forming a disk.
         a. Cysts rounded or elongate, single on stalks.
            Genus IV. *Podangium*, p. 1034.
         aa. Cysts rounded or elongate or pointed, numerous on the ends of stalks which may be branched.
            Genus V. *Chondromyces*, p. 1036.

Genus I. **Polyangium** *Link.*

(Link, Mag. d. Ges. Naturforsch. Freunde zu Berlin, *3*, 1809, 42; *Cystobacter* Schroeter, in Cohn, Kryptogamenflora v. Schlesien, *3*, 1, 1886, 170; *Myxobacter* Thaxter, Bot. Gaz., *17*, 1892, 394.)

Etymology: Greek *poly*, many and *angion*, vessels, referring to the numerous cysts.

Diagnosis: Cysts rounded or coiled, surrounded by a well-developed membrane, either free or embedded in a second slimy layer.

The type species is *Polyangium vitellinum* Link.

Key to the species of genus **Polyangium.**

I. Not parasitic on water plants (algae).
   A. Sorus not white or grayish in color.
      1. Cysts rounded to spherical.
         a. Ripe cysts yellow, reddish-yellow, orange or light red; not brown.
            b. Cysts several or numerous and small.
               c. Not closely appressed.
                  d. Slime envelope transparent white or colorless.
                     e. Usually 10 to 15 cysts. Rods in cysts, 3 microns long. Cysts 75 to 200 microns.
                        1. *Polyangium vitellinum.*

ee. Cysts numerous. Rods 1.3 to 2.0 microns long. Cysts 20 to 80 microns.
2. *Polyangium minus.*
dd. Slime envelope bright yellow.
3. *Polyangium luteum.*
cc. Closely appressed; often polygonal due to pressure.
d. Bright yellow.
4. *Polyangium morula.*
dd. Orange.
5. *Polyangium cellulosum.*
bb. Cysts single, large.
c. Large, 250 to 400 microns; reddish-yellow.
6. *Polyangium simplex.*
cc. Smaller, 30 to 60 by 50 to 130 microns; orange to light red.
7. *Polyangium ochraceum.*
aa. Ripe cysts reddish-brown to dark brown.
b. Cysts lying free, covered by a more or less definite slime envelope.
c. About 60 microns in diameter; slime envelope delicate and colorless.
8. *Polyangium fuscum.*
cc. About 35 microns in diameter; slime envelope yellow.
9. *Polyangium aureum.*
bb. Cysts rounded, in stellate arrangements on a slimy substrate.
10. *Polyangium stellatum.*
2. Cysts elongate, coiled.
a. Cysts brownish-red.
11. *Polyangium ferrugineum.*
aa. Cysts bright orange-yellow.
12. *Polyangium indivisum.*
B. Sorus white or gray in color.
1. Hyaline slime envelope white, foamy in appearance; cysts average 28 by 34 microns.
13. *Polyangium spumosum.*
2. Sorus flat, crust-like, smoke-gray in color due to slime envelope; cysts average 36 by 44 microns.
14. *Polyangium fumosum.*
II. Aquatic, parasitic on *Cladophora.*
15. *Polyangium parasiticum.*

1. **Polyangium vitellinum** Link. (Link, Mag. d. Ges. Naturforschender Freunde zu Berlin, *3*, 1809, 42; *Myxobacter aureus* Thaxter, Bot. Gaz., *17*, 1892, 403.)

Etymology: Modern Latin *vitellus*, like an egg yolk.

Swarm stage (pseudoplasmodium): When rising to form cysts, milky white. Rods large, cylindrical, rounded at either end, 0.7 to 0.9 by 4 to 7 microns.

Fruiting body: Cysts golden yellow, usually relatively spherical, 75 to 150 microns, occasionally 200 microns in diameter, almost always surrounded by a white slimy envelope, about 10 to 15 cysts in a mass. Rods in the cysts about 3 microns in length.

Source and habitat: Thaxter (*loc. cit.*) on very wet wood and bark in swamps. Maine, Belmont. Jahn (1924, *loc. cit.*) states it is not common; on old wood, lying in moist ditches, also on old poplar bark which was kept moist in a dish, also found twice on rabbit dung.

Illustrations: Thaxter (*loc. cit.*) Pl.

25, Figs. 34–36. Zukal, Ber. d. deutsch. Bot. Ges., *15*, 1897, 542, Pl. 27, Figs. 6–10. Jahn, Kryptogamenflora d. Mark Brandenburg, V, Pilze I, Lief. 2, 1911, 199, Fig. 3. Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden. Geb. Borntraeger, Leipzig, 1924, 77, and Pl. II, Fig. 13.

2. **Polyangium minus** Krzemieniewski. (Acta Soc. Bot. Poloniae, *4*, 1926, 33.)

Etymology: Latin *minor*, less or small.

Swarm stage (pseudoplasmodium): Vegetative rods 0.4 to 0.6 by 3 to 7 microns.

Fruiting bodies: Cyst masses commonly cover the substrate to an area of 0.5 sq. mm. Cysts are spherical or oval, small, 20 to 80 by 20 to 50 microns, light rose in color, becoming brownish, embedded in a transparent colorless slime. Cyst membrane light colored, relatively thick, 0.5 to 1.0 micron, transparent, revealing the contents. Rods in cyst 0.8 to 1.0 by 1.3 to 2.0 microns.

Source and habitat: On rabbit dung sterilized and placed on soil (Poland). Rather rare. Relatively slow in appearance, only after many days.

Illustrations: Krzemieniewski (*loc. cit.*) Pl. IV, Fig. 47–48; Pl. V, Fig. 49.

3. **Polyangium luteum** Krzemieniewski. (Acta Soc. Bot. Poloniae, *5*, 1927, 98.)

Etymology: Latin *luteus*, saffron- or golden-yellow.

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: Golden yellow, consisting of a few cysts surrounded by a common bright yellow very thick slime wall. The cysts have colorless thin walls. Rods 0.7 to 0.8 by 3.8 to 5.8 microns.

Source and habitat: Isolated from soil on rabbit dung by Krzemieniewski (1927).

Illustration: Krzemieniewski (*loc. cit.*) Pl. V, Fig. 22, 23.

4. **Polyangium morula** Jahn. (Kryptogamenflora der Mark Brandenburg., V, Pilze I, 1911, 202.)

Etymology: Modern Latin from Greek *mōra*, mulberry. A diminutive referring to shape of cysts.

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: Cysts bright yellow, closely packed into a mulberry-shaped sorus; cysts with thick membrane (3 microns), often made polygonal by pressure, 20 to 35 microns, bound together by slime. The whole sorus is 100 to 200 microns broad. Rods in cysts about 3 microns in length. Jahn states he has not studied fresh cysts. In the older cysts the rods are difficult to observe.

Source and habitat: Observed once only by Jahn (*loc. cit.*) on rabbit dung.

Illustration: Jahn (1924, *loc. cit.*) Pl. 2, Fig. 21.

5. **Polyangium cellulosum** Imšenecki and Solntzeva.* (On aerobic cellulose-decomposing bacteria. Akademiia Nauk, Leningrad, Isvestiia, 1936, 1115; English summary, 1168.)

Etymology: Modern Latin *cellulosum*, cellulose.

Fruiting body: Rods at center of the colony non-motile, forming large orange aggregates. Shorter than those at margin: 0.7 to 0.9 by 3.4 to 5.6 microns. Later a concentration of cells occurs. Rods come closer together, form rounded or oval aggregates from which cysts become delimited. Cysts orange in color, 8 to 24 microns, average 20 to 25 microns. In addition to bacterial cells droplets of fat, 1.5 to 3.5 microns, are sometimes seen within the cyst. When treated with H_2SO_4, cysts are easily broken up under the cover glass. Fruiting bodies are composed of clumps of cysts. Fruiting bodies oval or pear-

* Translated from the original by E. V. Prostov, Iowa State College Library, Ames, Iowa.

shaped, 40 to 55 by 110 to 160 microns, reddish-brown. Covered with a slime membrane (flakes of dried slime). Each composed of 12 to 40 cysts which become polygonal from pressure. No cystophore, except those formed from slimy threads which have a stratified structure. Cysts sometimes arranged in chains.

Spores: 0.7 to 0.8 by 2.2 to 3.5 microns.

Vegetative cells: Thick, bent rods, with rounded ends, 0.8 to 1.2 by 3.5 to 8.5 microns. Motile, no flagella. Young rods have 1 chromatin granule, older have 2. Found in cellulose fibers at the margin of the colony. Fibers solidly stuffed near the margin. At the periphery individual cells may be seen.

Vegetative colony: Cysts germinate on filter paper producing vegetative colonies. Colonies large, orange, moist, increasing in size. The older colonies have orange margins while the center is dark brown, corresponding to the color of the fruiting bodies. Often show several concentric rings.

Physiology: Rods cover cellulose fibers, partially or completely destroying them. Paper becomes transparent.

Optimum temperature 18° to 22°C. At 30° growth very slow.

Grows only on wet cellulose; not in ordinary media. No growth in a hanging drop of broth.

Aerobic.

Source and habitat: Soil.

Illustrations: Imšenecki and Solntzeva (*loc. cit.*) Table II, 2; figures 1 to 5.

5a. *Polyangium cellulosun* var. *ferrugineum* Mishustin. (Microbiology, Moscow, 7, 1938, 427.)

Etymology: Latin *ferrugineus*, of the color of iron-rust.

Fruiting body: Composed of numerous cysts having definite wall. Mass of rods has a yellowish tinge, and the cysts are colored reddish-yellow. Color probably confined to the cyst walls. Cysts round or egg-shaped, or may be angular due to pressure. Each cyst contains numerous shortened rods. Cysts usually 12 to 40 microns in diameter. Numerous cysts grouped into fruiting bodies having bright red or drabbish red color when ripe. Form of fruiting body variable: most commonly rounded, ellipsoidal or biscuit-shaped, sometimes sausage-shaped. Cysts confined by an orange-colored slime membrane or envelope. No cystophore present. Fruiting bodies not easily broken up. Vary in size from 80 to 240 microns.

Spores: No data.

Vegetative cells: Long, flexible, non-flagellate cells, motile by crawling, 0.8 to 1.2 by 3.0 to 5.0 microns. Become shortened and highly refractile during fruiting body formation.

Vegetative colony: On silica gel with cellulose at first pale pink. After six days fruiting bodies of red color appear, together with free cysts and many non-encysted shortened rods. Fruiting bodies numerous at center of colony, and later form in concentric rings around center. Margin of colony composed of vegetative cells; periphery pink. Mature colonies 2 to 5 cm in diameter, bright red, becoming drabbish red; pigmentation appears to be confined to limited areas. Surface dull, moist. Margin not definite.

Physiology: Cellulose at center of colony completely destroyed; not entirely broken down under remainder of colony.

The author considers this a color variant of *Polyangium cellulosum* Imšenecki and Solntzeva.

Source: Isolated from the black soils of Eastern European Russia.

Habitat: Digests organic matter in soil.

5b. *Polyangium cellulosum* var. *fuscum* Mishustin. (Microbiology, Moscow, 7, 1938, 427.)

Etymology: Latin *fuscus*, dark, swarthy, dusky, tawny.

Fruiting body: Composed of individual cysts, each with separate cyst wall, and held together by a common slime membrane or envelope. Shortened rod-shaped spores inclosed within the cyst

walls. Cysts forming outside the large masses usually rounded; those within often polygonal or angular. Cysts 5 to 24 microns long, oval or egg-shaped. Encysted cells give cysts granular appearance. Ripe cysts brown to light brown in color; immature, yellow to pink. Fruiting bodies pinkish-yellow when young, becoming brown when ripened. Considerable variation in form: round, oval or sausage-shaped, and from 50 to 80 microns up to several hundred microns. Outer slime envelope often indistinct; no dried slime noticeable between the cysts.

Spores: No data.

Vegetative cells: Identical with those of *Polyangium cellulosum* var. *ferrugineum.*

Vegetative colony: A faint yellow cast on cellulose-silica gel after 2 to 3 days. Becomes yellow-orange to yellow-pink after 6 to 8 days, while center is brownish-gray. Margin pinkish to yellow-pink. Surface dull, moist. As fruiting bodies ripen, colony becomes darker, finally dark brown. Reaches diameter of 2 to 5 cm. Fruiting bodies often arranged in form of pigmented, closely set, concentric rings. Margin of colony not clearly defined. Usually regularly rounded or oval. Cellulose completely destroyed only at center of colony.

Source: Common in black soils of Sumy Experiment Station. Found only once in podzol soils.

Habitat: Digests organic matter in soil.

5c. *Polyangium cellulosum* var. *fulvum* Mishustin. (Microbiology, Moscow, 7, 1938, 427.)

Etymology: Latin *fulvus*, reddish-yellow, gold-colored.

Fruiting body: Rose or pink in color, composed of numerous cysts. Young cysts yellow to yellow-orange, becoming pink, rose or red, or pinkish-yellow. Cysts same shape as others of the species; 6 to 24 microns in diameter, average 10 to 12 microns; contain many short rods. Fruiting bodies vary in shape, often elongated, flagella (?)-shaped (columnar?), up to 20 to 25 by 350 to 450 microns. Also globular, mace-shaped, etc. Usually 25 to 40 by 50 to 80 microns. Cysts inclosed by outer common envelope or slime membrane. Easily broken up mechanically.

Spores: No data.

Vegetative cells: 0.8 to 1.2 by 3.5 to 6.0 microns.

Vegetative colony: On cellulose-silica gel form a hardly visible white (colorless ?) colony at 2 days. After 6 days becomes pink in color. Fruiting bodies first form near center. After 9 to 10 days central area reddish-pink while periphery has yellowish cast. Mature colony 2.5 to 7.5 cm in diameter, pink-orange color, fairly regularly round or oval in shape. Pigmented concentric rings of fruiting bodies.

Physiology: Cellulose entirely destroyed at center of colony and often at other points.

Source: Podzol soils of Timiriazev Agricultural Academy. Seldom in black soils of Sumy Experiment Station.

Habitat: Digests organic matter in soils.

5d. *Polyangium cellulosum* var. *luteum* Mishustin. (Microbiology Moscow, 7, 1938, 427.)

Etymology: Latin *luteus*, saffron-yellow, orange-yellow.

Fruiting body: Poorly organized agglomerations of colorless to yellow cysts inclosing sporulated cells. Cysts regularly egg-shaped to oval, 8 to 20 microns in diameter; predominantly 6 to 10 microns. Matured cysts loosely connected into rounded or elongate masses 40 to 80 by 100 to 150 microns. Ripe fruiting bodies easily pulled apart.

Spores: No data.

Vegetative cells: Similar to others of the species.

Vegetative colony: On cellulose colonies regularly rounded or oval, surface has moist appearance. Yellowish cast 2nd or 3rd day, becoming deeper yellow.

Ochre yellow formations resembling fruiting bodies by 5 to 6 days. Many free cysts at center of colony. Later colony becomes pale dirty-yellow, while periphery remains bright yellow. Sometimes one or two brightly pigmented rings consisting of agglomerations of fruiting bodies are found in older colonies. Mature colonies 1.5 to 3.0 cm in diameter.

Physiology: Filter paper completely destroyed at center of colony. Developed better below pH 7 (around pH 6) than others of the species.

Source: Isolated from soils of the Timiriazev Agricultural Academy. Common in podzol soils.

Habitat: Digests organic matter in soil.

6. **Polyangium simplex** Thaxter. (*Myxobacter simplex* Thaxter, Bot. Gaz., *18*, 1893, 29; Thaxter, Bot. Gaz., *37*, 1904, 414.)

Etymology: Latin *simplex*, simple, i.e., not compound.

Swarm stage (pseudoplasmodium): Rods, large, cylindrical, rounded at either end, 0.7 to 0.9 by 4 to 7 microns.

Fruiting bodies: Cysts single, very large, 250 to 400 microns, bright reddish yellow, irregularly rounded. Rods flesh colored in mass. Upon pressure adhering together in sheaves.

Source and habitat: Found by Thaxter (*loc. cit.*) in U. S. A. on very wet wood and bark in swamps.

7. **Polyangium ochraceum** Krzemieniewski. (Acta Soc. Bot. Poloniae, *4*, 1926, 34.)

Etymology: Modern Latin from Greek *ōchra*, yellow ochre, hence ochraceous.

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: The orange to light red fruiting body in form of a single spherical or oval cyst 60 to 80 by 50 to 130 microns, each with a thick yellow-brown membrane. The cyst content often (particularly in the oval cysts) is constricted by the membrane which penetrates deeply. From the side the cyst appears to be divided. Rods in cysts 0.5 by 4 to 8 microns.

Source and habitat: From sterilized rabbit dung on soil (Poland).

Illustrations: Krzemieniewski (*loc. cit.*) Pl. V, Fig. 50, 51.

8. **Polyangium fuscum** (Schroeter) Thaxter. (*Cystobacter fuscus* Schroeter, in Cohn, Kryptogamenflora v. Schlesien, *3*, 1, 1886, 170; Thaxter, Bot. Gaz., *37*, 1904, 414.)

Etymology: Latin *fuscus*, fuscus, brown.

Swarm stage (pseudoplasmodium): Rods slender, elongate, 0.6 by 5 to 12 microns. Grows readily on agar, also on dung agar. Baur states rods are 15 to 20 microns in length and move about 2 to 3 microns per minute in hanging drop, on agar 5 to 10 microns per minute.

Fruiting bodies: Cysts flesh-colored when young, chestnut brown when ripe, spherical, about 60 microns (Thaxter, 50 to 150 by 50 to 70 microns) in diameter, with definite membrane, lying in considerable numbers in large sori, usually 30 to 40 sometimes up to 100. The slime envelope is much more delicate and evanescent than in *P. vitellinum*. Occasionally a form is found with cysts measuring 100 microns: under these often lie kidney shaped cysts even 150 microns in length; apparently, a variety. Rods in cysts about 0.8 to 1.5 by 3 to 3.5 microns. Cysts (Baur) on dung decoction break in 10–12 hours, and rods pour out, apparently passively at first.

P. fuscum var. *velatum* Krzemieniewski differs from the type in that the membrane is thin, separated from cysts, folded.

Source and habitat: Thaxter (Bot. Gaz., *23*, 1897), on rabbit dung from southern California. Kofler (Sitzber. d. Kais. Akad. Wiss. Wien. Math.-Nat. Klasse., 122 Abt., 1913, 845) on rabbit dung, Vienna. Jahn (Die Polyangiden, Geb. Borntraeg., 1924), common on dung,

also occurs on decaying lichens and on poplar bark kept moist. Quite common in Polish soils according to Krzemieniewski (1927, *loc. cit.*).

Illustrations: Thaxter (1897, *loc. cit.*), Pl. 31, Figs. 37–39. Baur, Arch. Protistenkunde, *5*, 1905, Pl. 4, Figs. 14, 15, and 17. Quehl, Cent. f. Bakt., II Abt., *16*, 1906, Pl. 1, Figs. 8 and 16. Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger. Leipzig, 1924, Pl. 2, Fig. 12. Also Fig. A, p. 9. Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, 34, Pl. IV, Figs. 42–43, also var. *velatum* Plate IV, Figs. 44–46.

9. **Polyangium aureum** Krzemieniewski. (Acta Soc. Bot. Pol., 7, 1930, 255.)

Etymology: Latin, *aureus*, golden.

Separated from *Polyangium morula* on basis of pigmentation.

Fruiting body: Cysts reddish-brown, variable in number, embedded in yellow slime to form a sorus with a common slime envelope. Cysts nearly spherical or slightly elongate, averaging 32 by 37 microns. Cyst wall orange-yellow, about 3.0 microns thick. Older cysts contain shortened rods, a granular mass, and a colorless or yellowish oleaginous liquid.

Spores: Rod-shaped.

Vegetative cells: Straight rods, of uniform diameter, with rounded ends, 0.7 to 0.9 by 2.8 to 5.3 microns.

Habitat: Soil.

Illustrations: Krzemieniewski (*loc. cit.*) Plate XVII, Figs. 14–17.

10. **Polyangium stellatum** Kofler. (Sitzber. d. kais. Akad. Wiss. Wien, Math.-Nat. Klasse, 122 Abt., 1913, 19.)

Etymology: Latin *stellatus*, stellate.

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: Cysts elongate, 80 to 120 microns broad, 160 to 200 microns long, flesh-colored when young, brownish-red when old, star-shaped with 2 to 9 rays fixed by the narrowed base upon a kind of hypothallus.

Source and habitat: Found by Kofler (1913, *loc. cit.*) on hare dung at Vienna.

Illustrations: Kofler (1913, *loc. cit.*) Pl.?, Fig. 6.

11. **Polyangium ferrugineum** Krzemieniewski. (Acta Soc. Bot. Poloniae, *5*, 1927, 97.)

Etymology: Latin *ferrugineus*, dark red, like iron rust.

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: Irregular, branched and occasionally constricted coils. Branches of same diameter as the main tube. Cyst wall is brown-red. In the interior no differentiation is visible. Rods in cysts are relatively short and thick, 0.8 to 1.1 microns by 2 to 2.5 microns, not definitely arranged. Close to *Archangium gephyra*, but with cyst walls.

Source and habitat: Krzemieniewski (*loc. cit.*) from soil in Poland and on rabbit dung.

Illustrations: Krzemieniewski (*loc. cit.*) Pl. V, Fig. 21.

12. **Polyangium indivisum** Krzemieniewski. (Acta Soc. Bot. Poloniae, *5*, 1927, 97.)

Etymology: Latin *indivisus*, undivided.

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: Similar to *Polyangium ferrugineum*, but much smaller and bright orange-yellow. Enclosed in a similarly colored slime membrane. Interior of coils undifferentiated. Cyst rods 0.8 to 1.0 by 3 to 6 microns, straight, and rounded on ends. Arranged perpendicularly to the wall, giving a netted appearance resembling *Melittangium*.

Source and habitat: From soils in Poland, Krzemieniewski (1927, *loc. cit.*).

13. **Polyangium spumosum** Krzemieniewski. (Acta Soc. Bot. Pol., *7*, 1930, 254.)

Etymology: Latin *spumosus*, foaming, full of foam.

Fruiting body: Colorless sori embedded in hyaline slime forming a common envelope around the cysts. Surface white, foamy in appearance; cysts in irregularly rounded accumulations, 100 to 150 microns in diameter. Cysts usually spherical, sometimes elongate; 18 to 38 by 20 to 50 microns; average 28 by 34 microns. Cyst membrane colorless. Cysts contain bundles of shortened cells, a granular colorless mass, and a clear oleaginous fluid.

Spores: Shortened rods.

Vegetative cells: Straight rods, uniformly thick, with rounded ends; 0.6 to 0.8 by 3.9 to 6.8 microns.

Habitat: Soil.

Illustrations: Krzemieniewski (*loc. cit.*) Plates XVI–XVII, Figs. 10–13.

14. **Polyangium fumosum** Krzemieniewski. (Acta Soc. Bol. Pol., 7, 1930, 253.)

Etymology: Latin *fumosus*, smoky.

Fruiting body: A flat, crust-like layer of 2 to 20 (or more) cysts arranged to form a sorus. Sori rounded, up to 90 microns in diameter, or irregularly shaped; often elongate up to 400 microns long. Smoky-gray color due to surrounding slime walls. Outer profile of sheath (or cortex) irregular. Cyst wall 2.4 to 3.5 microns thick; cysts often nearly spherical, 13 to 48 microns in diameter, though frequently elongate. Average 36 by 44 microns. Colorless, single, inclosed in a transparent membrane.

Spores: No data.

Vegetative cells: Long, straight, cylindrical with rounded ends; 0.7 to 0.9 by 2.7 to 5.7 microns. Encysted cells similar.

Habitat: Soil.

Illustrations: Krzemieniewski (*loc. cit.*) Plate XVI, Figs. 6–9.

15. **Polyangium parasiticum** Geitler. (Arch. f. Protistenkunde, *50*, 1924, 67.)

Etymology: Latin *parasiticus*, parasitic.

Swarm stage (pseudoplasmodium): In water, on surface of the alga *Cladophora*. Pseudoplasmodia small. Rods long, cylindric, rounded at end and 0.7 by 4 to 7 microns. At first saprophytic, later entering and destroying the *Cladophora* cell.

Fruiting bodies: Sometimes single, usually 2 to 8 microscopically small, united in irregular masses, spherical or somewhat elongated. From 15 to 50 microns, usually 25 to 40 microns, with hyaline slime. When mature, red-brown in color, with firm wall.

Source and habitat: Found on *Cladophora (fracta?)* in pool at Vienna (Geitler, 1924).

Illustrations: Geitler (1924, *loc. cit.*) Figs. 1–10.

Genus II. Synangium *Jahn.*

(Jahn, Beiträge zur botan. Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 79; *Apelmocoena* Enderlein, Bakterien-Cyclogenie, Berlin, 1924, 243.)

Etymology: Greek *syn*, together and *angion*, vessel, referring to the clustering of the cysts.

Diagnosis: Cysts provided with an apical point, united more or less completely to rosette-shaped, hemispherical or spherical fruiting bodies.

The type species is *Synangium sessile* (Thaxter) Jahn.

Key to the species of genus Synangium.

I. Cysts irregular, pointed, united as a rosette on a slimy base, without a stalk.
   1. *Synangium sessile.*

II. The fused cysts on a simple or branched stalk.
   A. Cyst group spherical, with the points of the cysts covered as with hair, reddish.
      2. *Synangium lanuginosum.*

B. Cyst group an oblate spheroid, yellow. Points of cysts less numerous.
3. *Synangium thaxteri.*

1. **Synangium sessile** (Thaxter) Jahn. (*Chondromyces sessilis* Thaxter, Bot. Gaz., *37*, 1904, 411; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 79.)

Etymology: Latin *sessilis*, sessile, not stalked.

Swarm stage (pseudoplasmodium): Not described.

Fruiting body: Cysts form on the base a clump or rosette without trace of stalk. Diameter of rosettes 100 to 250 microns. Individually the cysts are quite variable in form, irregularly spindle-shaped, usually short-pointed, wrinkled surface toward the tip. At the base they fuse or unite to irregular masses. Cysts 18 to 55 by 25 to 75 microns, average 40 by 50 microns.

Source and habitat: Thaxter (*loc. cit.*) found this on decaying wood in Florida.

Illustration: Thaxter (*loc. cit.*) Pl. 27, Figs. 14–15.

2. **Synangium lanuginosum** (Kofler) Jahn. (*Chondromyces lanuginosus* Kofler, Sitzber. d. Kais. Akad. Wiss. Wien. Math.-Nat. Klasse, 122 Abt., 1913, 861; Jahn, Beiträge zur botanischen Protistologie. I. Polyangiden, Geb. Borntraeger, Leipzig, 1924, 79.)

Etymology: Latin *lanuginosus*, woolly.

Swarm stage (pseudoplasmodium): Not described.

Fruiting body: Cyst cluster, consisting of united cysts, spherical or oval, 80 to 200 microns in diameter, when dry, dark flesh-colored, covered with hairs 15 to 50 microns long, originating from the individual cysts and giving the cyst cluster the appearance of a hairy ball. Skin of the cysts not definite. Rods within the cysts 3 to 6 microns. The cyst clusters are terminal on more or less forked stalks, about 1 mm high.

Source and habitat: Kofler (*loc. cit.*) found this on rabbit dung at Vienna.

Illustrations: Kofler (*loc. cit.*) Pl. 1, Figs. 1–3.

3. **Synangium thaxteri** (Faull) Jahn. (*Chondromyces thaxteri* Faull, Bot. Gaz., *62*, 1916, 226; Jahn, Beiträge zur botanischen Protistologie, I. Die Polyangiden. Geb. Borntraeger, Leipzig, 1924, 79.) Regarded as a synonym of *Synangium lanuginosum* by Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, 39.

Etymology: Named for Dr. Roland Thaxter, American botanist.

Swarm stage (pseudoplasmodium): Cultured for 2 years on dung, best in mixed cultures. Rods 0.5 by 3 to 6 microns.

Fruiting body: Fruit cluster flattened, spherical, yellow to flesh color or reddish-orange, with a stalk which varys in length, about 140 microns in diameter. The bristles corresponding to the single cysts are 15 to 30 microns long, at the base 10 to 12 microns wide. Sometimes cyst single, usually 3 to 4, occasionally 20 to 30. Rods 0.5 by 3 to 6 microns. Stalk maximum length 0.75 mm, usually 350 microns, single or branched. Broad based, narrowing to apex and yellow in color. In germination rods move from basal scar of membrane, leaving the empty sack behind.

Source and habitat: On deer dung in Ontario, Canada (Faull).

Illustrations: Faull (*loc. cit.*) Pl. 5 and 6. Jahn (*loc. cit.*) Fig. X, p. 80.

Genus III. **Melittangium** *Jahn.*

(Jahn, Beiträge zur botan. Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 78.)

Etymology: Greek *melitta*, bee and *angion*, vessel, because of the honey-comb pattern of the membrane.

Diagnosis: Cysts brownish orange-red, on short white stalk, like a mushroom. Has appearance of a white-stalked *Boletus*. The rods inside stand at right angles to the membrane. Upon germination the covering membrane is left colorless and with an appearance of honey-comb.

The type species is *Melittangium boletus* Jahn.

1. **Melittangium boletus Jahn.** (Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 78.)

Etymology: Latin *boletus*, a kind of mushroom.

Swarm stage (pseudoplasmodium): No description.

Fruiting bodies: Cyst stalked, mushroom-like, white when immature, then yellowish-flesh colored, finally yellowish-brown to nut brown, when dried more reddish-brown. Larger diameter of cyst about 100 microns, height 40 to 50 microns, length of white stalk about 40 microns, length of rods in the cyst 3 to 4 microns by 0.5 microns. Sometimes the cyst is smaller and spherical (50 to 60 microns diameter), sometimes there is fusion of neighboring cysts, occasionally the stalk is abortive.

Source and habitat: Jahn (*loc. cit.*) found this not uncommon on rabbit and deer dung in the vicinity of Berlin, also on deer dung from Denmark. Krzemieniewski (1927, *loc. cit.*) reported it as common in Polish soils.

Illustrations: Jahn (*loc. cit.*), Pl. 2, Fig. 17 and 18. Also Fig B, p. 11, C-F, p. 23, O-Q, p. 43, T-U, p. 55. Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, 1, Pl. V, Fig. 55-56.

Genus IV. Podangium *Jahn.*

(*Cystobacter* Schroeter, in Cohn, Kryptogamenflora v. Schlesien, *3*, 1, 1886, 170; Jahn, Beiträge zur botan. Protistologie. I. Die Polyangiden. Geb. Borntraeger, Leipzig, 1924, 80; *Monocystia* Enderlein, Bakterien-Cyclogenie, Berlin, 1924, 243.)

Etymology: Greek *pus, podis*, foot and *angion*, vessel.

Diagnosis: Cysts chestnut-brown or red-brown, single on a more or less definite white stalk.

The type species is *Podangium erectum* (Schroeter) Jahn.

Key to the species of genus Podangium.

I. Stalk scarcely definite, cysts short, appressed, if elongate then passing over from the white stem into the club-shaped cyst. Ripe cysts chestnut-brown.
   1. *Podangium erectum.*

II. Stalk well differentiated.
   A. Cysts spherical, often irregular, confluent, the white stalk short.
      2. *Podangium lichenicolum.*
   B. Cysts lengthened ellipsoidal, red-brown, definitely differentiated from the white, slender stalks.
      3. *Podangium gracilipes.*

1. **Podangium erectum** (Schroeter) Jahn. (*Cystobacter erectus* Schroeter, in Cohn, Krytogamenflora v. Schlesien, *3*, 1, 1886, 170; *Chondromyces erectus* Thaxter, Bot. Gaz., *23*, 1897, 407; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 80.)

Etymology: Latin *erectus*, erect, upright.

Swarm stage (pseudoplasmodium): Kofler states rods are 2 to 5 microns in length.

Fruiting bodies: Cysts usually short, almost spherical, compact, rounded above, orange-red changing to chestnut-brown, single on a white to yellow hypothallus constituted from the slime remaining behind. A definite "foot" of whitish slime is seldom observed. Fifty to hundreds together. Usually about 80 microns high and 40 to 50 microns broad above, smaller below, often spherical cysts 60 microns in diameter. Rods in cysts 0.6 by 4 microns.

Jahn believes the European form to be distinct from that described by Thaxter. Thaxter's form produces cystophores 60 to 300 microns long which wither at maturity so that cysts appear sessile.

Source and habitat: Thaxter (*loc. cit.*), horse dung in laboratory cultures, Massachusetts. Kofler (Sitzber. d. Kais. Akad. Wiss. Wien. Math.-Nat. Klasse, 122 Abt., 1913), mouse dung. Jahn (1924) common on manure of different kinds, also on bark covered with lichens. Krzemieniewski (Acta Soc. Bot. Pol., *5*, 1927, 102) reported this species from Polish soil, but rare.

Illustrations: Thaxter (*loc. cit.*) Pl. 31, Figs. 16–19. Quehl, Cent. f. Bakt., II Abt., *16*, 1906, Pl. 1, Figs. 4. Jahn (*loc. cit.*) Pl. I, Figs. 7, 8, and 9. Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, 1, Pl. V, Figs. 52–53.

2. **Podangium lichenicolum** (Thaxter) Jahn. (*Chondromyces lichenicolus* Thaxter, Bot. Gaz., *17*, 1892, 402; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 81.)

Etymology: Greek *lichen*, tree moss, lichen. Latin *-colus*, dwelling.

Swarm stage: Reddish, rods cylindrical, tapering slightly, 0.6 by 5 to 7 microns. Germinate readily after drying for 18 months when sown on moist lichens.

Fruiting bodies: Cysts single, rounded or irregularly lobed, often confluent. Cystophore short, squarish, often lacking or misshapen. Cysts 28 to 35 microns, stem 7 to 8 by 10 microns.

Source and habitat: Thaxter (1892), parasitic upon living lichens, which it destroys, New Haven, Conn. Thaxter (1904, *loc. cit.*), lichens, Indiana, on algae, seen on wet boards, in mill race, Massachusetts.

Illustrations: Thaxter (1892, *loc. cit.*) Pl. 23, Figs. 20 to 23. Quehl, Cent. f. Bakt., II Abt., *16*, 1906, 9, Pl. 1, Fig. 6.

3. **Podangium gracilipes** (Thaxter) Jahn. (*Chondromyces gracilipes* Thaxter, Bot. Gaz., *23*, 1897, 406; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 82.)

Etymology: Latin *gracilipes*, slender footed.

Swarm stage: Rods 5 to 7 microns.

Fruiting bodies: Cysts bright orange-red, or red, 25 by 35 microns, elongate, rounded, on a white pointed stalk, rigid and persistent on substratum, rods also in stalk. Shortened rods in cyst 3 to 5 microns. Cysts sometimes pear-shaped, caducous.

Source and habitat: Thaxter (*loc. cit.*), from rabbit dung, Massachusets. Kofler (1913, *loc. cit.*), dung, Vienna. Jahn (*loc. cit.*) relatively common. Twice on rabbit dung near Berlin, once on goat dung in Norway. Krzemieniewski (1927 *loc. cit.*) reported this species from Polish soil, but rare.

Illustrations: Thaxter (*loc. cit.*) Pl. 31, Figs. 20–24. Quehl, Cent. f. Bakt., II Abt., *16*, 1906, Pl. 1, Fig. 12. Jahn (*loc. cit.*) Pl. II, Figs. 19, 20. Krzemieniewski (1926, *loc. cit.*), Pl. V, Fig. 54.

Genus V. **Chondromyces** *Berkeley and Curtis.*

(See Berkeley, Introduction to Cryptogamic Botany, London, 1857, 313; *Stigmatella* Berkeley and Curtis, *ibid.* 1857, 313 (figure but no description); Berkeley (description), Notes on North American Fungi, Grevillea, *3*, 1874, 97; see Berkeley and Curtis, in Saccardo, Sylloge Fungorum, *4*, 1886, 679, *Polycephalum*? Kalchbrenner and Cooke, Grevillea, *9*, 1880, 22; *Myxobotyrs* Zukal, Ber. d. deutsch. Bot. Gesellsch., *14*, 1896, 346; *Cystodesmia* Enderlein, Bakterien-Cyclogenie, Berlin, 1924, 243.)

Synonymy: A species was figured and named in 1857 by Berkeley as *Chondromyces crocatus* Berkeley and Curtis, but not described. The generic name was finally described in 1874. Probably the date of the name should be the date of its description, although it is possible that an adequate labeled illustration should be interpreted as valid publication.

Etymology: Greek *chondros*, grain and *myces*, (fungus).

Diagnosis: Cysts compactly grouped at the end of a colored stalk (cystophore). Cystophore simple or branched.

The type species is *Chondromyces crocatus* Berkeley and Curtis.

Key to the species of genus **Chondromyces.**

I. Cysts not in chains.
  A. Cysts sessile when ripe.
    1. Cysts not pointed.
      a. Cysts rounded.
        b. Yellow.
          1. *Chondromyces crocatus.*
        bb. Bright orange-red.
          2. *Chondromyces aurantiacus.*
      aa. Cysts cylindrical.
          3. *Chondromyces cylindricus.*
    2. Cysts pointed.
          4. *Chondromyces apiculatus.*
  B. Cysts borne on stalk or stipe when ripe.
    1. Cysts orange-colored and truncate or rounded at distal end.
      a. Cystophore usually simple.
          5. *Chondromyces pediculatus.*
      aa. Cystophore usually branched.
          6. *Chondromyces medius.*
    2. Cysts copper-red when ripe; pear-shaped.
          7. *Chondromyces minor.*
II. Cysts in chains at end of a compact stalk.
          8. *Chondromyces catenulatus.*

1. **Chondromyces crocatus** Berkeley and Curtis. (Berkeley, Introduction to Cryptogamic Botany, London, 1857, 313; Berkeley, Notes on North American Fungi, Grevillea, *3*, 1874, 64; *Myxobotyrs variabilis* Zukal, Ber. d. deutsch. bot. Ges., *15*, 1896, 340, according to Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, 38.)

Etymology: Latin *crocatus*, saffron yellow.

Swarm stage (pseudoplasmodium): Pale orange-red. Rods cylindrical or tapering slightly, straight or slightly curved, 0.6 to 0.7 by 2.5 to 6 microns. Cultivated on nutrient agar and sterilized horse dung. Cysts placed in moist chamber germinate in one or two days.

The contents are first contracted within the cyst walls, showing the individual rods. The cyst wall is then absorbed or disappears at the base, and the rods escape in a regular stream until only the empty cyst is left.

Fruiting bodies: Cysts nearly conical, rounded at tip, average 12 by 28 microns (6 to 20 by 15 to 45 microns), straw yellow, in spherical heads of variable numbers (70 to 90 microns) at tips of branches. Cystophore orange-colored, slender, striated, often twisted or irregularly bent, simple or branched as many as 5 times. About 600 microns high, rarely 1 mm.

Source and habitat: Thaxter (1892, *loc. cit.*), melon rind from South Carolina and old straw from Ceylon and Cambridge, Mass. Zukal (*loc. cit.*), Vienna. Quehl, dung from Java and on deer dung, near Berlin. Thaxter (1904, *loc. cit.*), New Haven, Conn., Tabor, Iowa, Florida, Laubach, Java.

Illustrations: Berkeley, Introduction to Cryptogamic Botany, London, 1857, 313. Thaxter, Bot. Gaz., *17*, 1892, 389, Pl. 22 and 23, Figs. 1–11. Quehl, Cent. f. Bakt., II Abt., *16*, 1906, 9, Pl. 1, Fig. 10. Jahn, Kryptogamenflora der Mark Brandenburg, V, Pilze I, Lief 2, 1911, 199, Fig. 6. Jahn, Beiträge zur botanischen Protistologie, I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, Pl. 2, Figs. 14, 15, and 16.

2. **Chondromyces aurantiacus** (Berkeley and Curtis) Thaxter. (*Stigmatella aurantiaca* Berkeley and Curtis (no description), Introduction to Cryptogamic Botany, London, 1857, 313; Berkeley (description), Notes on North American Fungi, Grevillea, *3*, 1874, 97; *Stilbum rhytidosporum* Berkeley and Browne, 1873, 96, see Saccardo, Sylloge Fungorum, *4*, 1886, 571; *Polycephalum aurantiacum* Kalchbrenner and Cooke, Australian Fungi, Grevillea, *9*, 1880, 23; *Myxobotrys variabilis* Zukal, Ber. deutsch. Bot. Ges., *14*, 1896, 340; *Chondromyces aurantiacus* Jahn, Kryptogamenflora der Mark Brandenburg, V, Pilze I, 1911, 206.)

Etymology: Modern Latin *aurantiacus*, orange-colored.

Swarm stage (pseudoplasmodium): Flesh-colored, distinctly reddish. Rods large, tapering somewhat, normally straight, rounded at either extremity, 0.6 to 1 by 7 to 15 microns, average 0.5 by 7 microns (?). Easily cultivated on nutrient agar, but on this rarely produces well formed cystophores, though cultivable on its ordinary substrate without difficulty.

Fruiting bodies: Cysts oval, elliptical or spherical, average 30 by 50 microns, at first stalked then sessile, united in small numbers at one end of cystophores, bright orange-red, chestnut-brown when kept moist for a considerable period or flesh-colored. Cystophore colorless, often yellowish at the tip, usually simple, rarely forked, 200 to 400 microns high.

The Krzemieniewskis (Acta Soc. Bot. Poloniae, *5*, 1927, 96) have described a *Chondromyces aurantiacus* var. *frutescens* in which the fruiting body consists of a greenish, later yellowish mass of rods which develops into a thick cystophore with numerous terminal cysts. The cysts are oval or spherical, sometimes with cross-striations, first orange-colored, later brown, about 40 to 120 by 30 to 90 microns. The cyst rods are 0.9 to 1.0 by 2.3 to 3.4 microns.

Source and habitat: Berkeley (1857, *loc. cit.*), on lichen. Berkeley and Brown (1873, *loc. cit.*), on rotten wood from Ceylon. Thaxter (1892, *loc. cit.*) in North America not uncommon on old wood and fungi. Zukal (*loc. cit.*), Vienna. Thaxter, Bot. Gaz., *23*, 1897 395, on antelope dung from Africa. Thaxter, Bot. Gaz., *37*, 1904, 405, Florida, Philippines. Quehl, Cent. f. Bakt., II Abt., *16*, 1906, 9, dung from Java. Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, 1, rare in Polish soils.

Illustrations: Berkeley and Brown

(1873, *loc. cit.*) Pl. 4, Fig. 16. Kalchbrenner and Cooke (*loc. cit.*). Thaxter (1892, *loc. cit.*) Pl. 23 and 24, Figs. 12–19 and 25–28. Zukal (*loc. cit.*) Pl. 20. Quehl (*loc. cit.*) Pl. 1, Fig. 10. Jahn, Beiträge zur botanischen Protistologie, I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, Fig. V, p. 57, Fig. W, p. 59. Krzemieniewski (1926, *loc. cit.*), Pl. V, Figs. 57–60; (1927) var. *frutescens* Pl. VI, Figs. 27–35.

3. **Chondromyces cylindricus** Krzemieniewski. (Acta Soc. Bot. Pol., *7*, 1930, 260.)

Etymology: Greek *kylindrikos*, cylindrical.

This organism was at first thought to be a variety of *Chondromyces aurantiacus*. It is separated from it on the basis of size, shape and pigmentation of the cysts.

Fruiting body: Cystophore composed of bundles of cells, develops from a thick, greenish-yellow mass of rods; unbranched or with short branches, colorless to pale orange-yellow; up to 200 microns high. Numerous cysts develop from cystophore and branches; at first borne on slender stipe 20 microns long, later becoming sessile on cystophore. Young cysts orange-yellow, later becoming deeper orange, and finally bright orange-brown when ripe. Shape variable: oval, irregularly rounded; predominantly cylindrical with rounded ends, 16 to 49 by 30 to 90 microns; average 29 by 56 microns.

Spores: Shortened rods 0.8 to 1.1 by 1.8 to 3.3 microns.

Vegetative cells: Long rods, tapered at ends, 0.5 to 0.6 by 6.7 to 11.0 microns.

Habitat: Soils.

Illustrations: Krzemieniewski (*loc. cit.*) Plate XVII, Fig. 18.

4. **Chondromyces apiculatus** Thaxter. (Bot. Gaz., *23*, 1897, 405.)

Etymology: Modern Latin from Latin *apex*, a point: with a small point.

Swarm stage (pseudoplasmodium): Rods 1 by 3 to 20 microns. Does not grow as well on nutrient agar as *Chondromyces crocatus* and produces cysts and cystophores rarely. Cultivated on dung. Kofler states rods are 3 to 5 microns in length.

Fruiting bodies: Cysts of variable form, cylindrical to broadly turnip-shaped, usually with basal and apical appendages, the latter longer and pointed, bright orange, 28 by 35 microns. Cysts united in a single spherical terminal head, about 200 microns in diameter. Cystophore rigid, stiff, seldom branched, to 1 mm high, colorless, longitudinally striate. Cysts germinate at both base and apex.

Source and habitat: Thaxter (1897, *loc. cit.*), on antelope dung from Africa. Thaxter (1904, *loc. cit.*), deer dung, Philippines, Florida. Baur (1906, *loc. cit.*), on rabbit dung near Berlin. Kofler (1913, *loc. cit.*), on rabbit dung near Vienna.

Illustrations: Thaxter (1897, *loc. cit.*) Pl. 30, Figs. 1 to 15. Quehl (1906, *loc. cit.*), Pl. 1, Figs. 13 to 14. Jahn (1911, *loc. cit.*) p. 199, Fig. 5.

5. **Chondromyces pediculatus** Thaxter. (Bot. Gaz., *37*, 1904, 410.)

Etymology: From Latin *pediculus*, a small foot; small footed (stalked).

Swarm stage (pseudoplasmodium): Rods 0.6 to 0.7 by 2 to 4 microns.

Fruiting bodies: Cysts rounded to bell-shaped, truncate at distal end, orange-yellow, when dry orange-red, 35 to 50 microns. Sessile on stalks 40 to 60 microns in length, which are arranged as an umbel on the tip of the cystophore. Cystophore 300 to 700 microns in length, solitary, simple, usually rather slender and somewhat wrinkled.

Source and habitat: Thaxter (*loc. cit.*), on goose dung in South Carolina.

Illustrations: Thaxter (*loc. cit.*) Pl. 26, Figs. 7 to 13.

6. **Chondromyces medius** Krzemieniewski. (Acta Soc. Bot. Pol., *7*, 1930, 263.)

Etymology: Latin *medius*, medial, moderate.

Fruiting body: Glistening, orange-colored cysts attached to cystophore in clusters by means of filamentous stipes about 40 microns long. Deciduous. Mass of rod-shaped cells from which cystophore develops colorless to pink. Cystophore composed of bundles of cells, often branched; appear similar to those of *Chondromyces aurantiacus* var. *frutescens*. Cysts variable in shape; predominant are those rounded or flattened at the apex and tapered toward the base, 24 to 78 by 26 to 93 microns. Average 51 by 55 microns.

Spores: No data.

Habitat: Soil.

Illustrations: Krzemieniewski (*loc. cit.*) Plate XVII, Figs. 20–22.

7. **Chondromyces minor** Krzemieniewski. (Acta Soc. Bot. Pol., 7, 1930, 265.)

Etymology: Latin *minor*, less, little, small.

Fruiting body: Cell masses from which cystophore develops, reddish-violet in color. Cystophore white, simple or branched, up to 120 microns high, 17 to 89 microns thick. Cysts borne in clumps of 2 to 20 at apex of cystophore and branches on delicate colorless stipes. Cysts rose-red becoming copper-red when dry; pear-shaped, tapering toward base and broad at the apex; 20 to 47 by 20 to 65 microns; average 28 by 38 microns. Deciduous. Stipes 3 to 6 by 10 to 25 microns.

Spores: 0.6 to 0.8 by 2.9 to 4.3 microns.

Vegetative cells: 0.6 by 3.8 to 7.2 microns.

Habitat: Soil.

Illustrations: Krzemieniewski (*loc. cit.*) Plate XVII, Figs. 23–24.

8. **Chondromyces catenulatus** Thaxter. (Bot. Gaz., *37*, 1904, 410.)

Etymology: Modern Latin from *catena*, a chain, = occurring in chains.

Swarm stage (pseudoplasmodium): Cultivated only on original substrate. Rods 1 to 1.3 by 4 to 6 microns.

Fruiting bodies: Cysts light yellow-orange, 20 to 50 by 18 microns in rosary-like chains, which may be branched once or twice, sessile on a short compact stalk, cysts separated by shriveled isthmuses. Chains to 300 microns. Cystophore simple 180 to 360 microns, cleft above, and passing over into the chains, rather broad at base and spreading somewhat on substratum. The divisions of the cystophore are pointed, short and slightly swollen.

Source and habitat: Thaxter (*loc. cit.*), on decaying poplar wood, New Hampshire.

Illustrations: Thaxter (*loc. cit.*) Pl. 26, Figs. 1 to 5.

FAMILY V. MYXOCOCCACEAE JAHN.

(Beiträge zur botan. Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 84.)

Diagnosis: The rods become shortened when fruiting occurs (resting cells are formed), and develop into spherical or ellipsoidal spores or microcysts. Upon germination the vegetative cell develops from the spore by a process analogous to budding, pinching off at the point of emergence, leaving the spore wall entirely empty. In three of the genera, definite fruiting bodies are produced. In *Sporocytophaga*, the spores (microcysts) are produced from the vegetative cells without development of fruiting bodies.

Key to the genera of family **Myxococcaceae.**

I. Definite fruiting bodies formed.
  A. Fruiting body not containing or made up of cysts.
    1. Fruiting bodies deliquescent.
      Genus I. *Myxococcus*, p. 1040.
    2. Fruiting bodies firm, not deliquescent.
      Genus II. *Chondrococcus*, p. 1044.
  B. Fruiting body made up of cysts.
    Genus III. *Angiococcus*, p. 1047.
II. No definite fruiting bodies formed.
  Genus IV. *Sporocytophaga*, p. 1048.

Genus I. **Myxococcus** *Thaxter.*

(Bot. Gaz., *17*, 1892, 403.)

Etymology: Greek *myxa*, mucus and *kokkos*, berry; slime sphere.

Diagnosis: Spherical spores in conical or spherical or occasionally ovoid upright fruiting bodies, united by a loose more or less mobile slime.

The type species is *Myxococcus fulvus* (Cohn *emend.* Schroeter) Jahn.

Key to the species of genus **Myxococcus.**

I. Stalk lacking or indicated only by a constriction.
  A. Spores average less than 1.4 microns in diameter.
    1. Fruiting body red or brownish-flesh color.
      1. *Myxococcus fulvus.*
    2. Fruiting body light blood-red.
      2. *Myxococcus cruentus.*
  B. Spores average 2.0 microns in diameter.
    1. Fruiting body yellow to greenish-yellow.
      3. *Myxococcus virescens.*
    2. Fruiting body yellow-orange to orange.
      4. *Myxococcus xanthus.*
II. Well developed stalk supporting spherical spore mass above.
  A. Spores spherical.
    5. *Myxococcus stipitatus.*
  B. Spores oval.
    6. *Myxococcus ovalisporus.*

1. **Myxococcus fulvus** (Cohn *emend.* Schroeter) Jahn. (*Micrococcus fulvus* Cohn?, Beiträge z. Biologie d. Pflanzen, *1*, Heft 3, 1875, 181; Jahn (1924) states that the description of Cohn is too inadequate to determine whether he was dealing with a true species of the genus *Myxococcus*. Cohn described the organism from horse dung, as producing conical, rust-red droplets ½ mm in diameter, the cells bound together by an intercellular slime, cells large, 1.5 microns in diameter; *Micrococcus fulvus* Schroeter, Schizomycetes, in Cohn, Kryptogamenflora v. Schlesien, *3*, 1, 1886, 144. Observed on horse dung and rabbit dung at various localities. Jahn insists that this organism must be the same as *Myxococcus rubescens* Thaxter. *Myxococcus rubescens* Thaxter, Bot. Gaz., *17*, 1892, 403; *Myxococcus ruber* Baur, Arch. f. Protistenkunde, *5*, 1905, 95; *Myxococcus pyriformis* A. L. Smith, Jour. Bot., *39*, 1901, 71; *Myxococcus javanensis* de Kruyff, Cent. f. Bakt, II Abt., *21*, 1908, 386; *Rhodococcus fulvus* Winslow and Winslow, Systematic Relationships of the Coccaceae, 1908, 262; *Myxococcus fulvus* Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 84.)

Etymology: Latin *fulvus*, reddish-yellow.

Swarm stage (pseudoplasmodium): Thaxter states that the rod masses are reddish, rods slender, irregularly curved, 0.4 by 3 to 7 microns. Bauer followed spore germination in hanging drop. Spores 0.8 to 1.3 microns, without structure, in five hours swollen to 1 to 1.5 microns, and no longer as refractive. The membrane is not burst; the cell becomes egg-shaped, then elongate and cylindric. He regards his *Myxococcus ruber* as distinct from Thaxter's *Myxococcus rubescens* in part because of differences in spore germination. The cells become motile after doubling or trebling in length. It is a creeping motion in contact with the substrate; the cells do not "swim." Rate of motion 5 to 10 microns per minute. Rods eventually are 0.5 to 0.7 microns by 4 to 10 microns. Cell division by transverse fission. Spore formation is through shortening and rounding of the cells, the converse of germination. In hanging drop the cells tend to congregate after three days and to transform into spores. Rods sporulate in 3 to 4 hours. The rods continue to congregate, and the spore mass increases, held together by viscous matrix. Vegetative cells are light flesh color.

Gelatin is quickly liquefied, completely in 1 to 2 days, but no fruiting bodies are formed.

Kofler secured good growth on Hasting's milk agar, and determined digestion of casein.

Baur could not secure good growth on any agar medium of known composition. With peptone, sugars, etc., some growth but not normal when peptone present. He carried one strain 3½ months on peptone sugar agar. Good growth on dung agar. Addition of peptone to dung agar not significant in effect, the addition of glucose altered the form of the fruiting bodies.

De Kruyff secured best results with a dung extract agar to which was added ammonium nitrate and potassium phosphate.

Fruiting bodies: Spherical or elongate pear-shape, constricted below, often with definite slimy stalk, flesh red to brownish-red, when dry rust-red to brown, about 300 microns in diameter. Spores 1 to 1.2 microns. Jahn (1924, *loc. cit.*) notes two varieties.

- var. *albus*. (Latin *albus*, white). Constantly white, even when transferred. Fruiting bodies somewhat smaller than the type.
- var. *miniatus*. (Latin *miniatus*, painted with red lead or cinnabar.) Color cinnabar-red, fruiting bodies somewhat larger.

The form described by de Kruyff had spores 1.6 microns in diameter.

Source and habitat: Thaxter (1892, *loc. cit.*), on various decaying substances, lichens, paper, dung, etc. Smith (*loc. cit.*), on rabbit dung from Wales. Baur (*loc. cit.*), on cow and dog dung. De Kruyff (*loc. cit.*), on stable manure in Java. Jahn (1924, *loc. cit.*), very common, on almost all specimens of dung, also on bark, decaying wood, and lichens. Krzemieniewski (1927, *loc. cit.*) very common in Polish soil. Kofler (*loc. cit.*), dung of rabbit, horse, goat, mouse, roe, deer, on stem of clematis and decaying leaves and in bird nest.

Illustrations: Cohn (*loc. cit.*) Pl. 6, Fig. 18. Smith (*loc. cit.*) Fig. 1. Baur (*loc. cit.*) Figs. 1, 2, 3, and Pl. 4, Figs. 1–13, 16. Jahn (1924, *loc. cit.*) Figs. L–M, p. 43, Fig. R, p. 47. Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, Pl. I, Figs. 7–8. Kofler, Sitzber. d. Kais. Akad. Wiss. Wien. Math.-Nat. Klasse, 122 Abt., 1913, 845, Pl. 2, Figs. 10 and 12.

Cultures: Baur (*loc. cit.*) states that he deposited a pure culture in the Zentralstelle für Pilzkulturen.

2. **Myxococcus cruentus** Thaxter. (Thaxter, Bot. Gaz., *23*, 1897, 395; *Chondrococcus cruentus* Krzemieniewski, Acta Soc. Bot. Poloniae, *5*, 1927, 79.)

Etymology: Latin *cruentus*, blood-red.

Swarm stage (pseudoplasmodium): Rods 0.8 by 3 to 8 microns. Was not cultivated.

Fruiting body: Cysts regularly spherical, 90 to 125 microns, blood-red. Slime forms on the surface a more or less definite membrane, in which the spores lie. Spores oval or irregularly oblong about 0.9 to 1 by 1.2 to 1.4 microns. Cysts are densely aggregated.

Source and habitat: Thaxter (*loc. cit.*), on cow dung, Tennessee. Krzemieniewski (1927, *loc. cit.*) rare in Polish soils.

Illustrations: Thaxter (*loc. cit.*) Pl. 31, Figs. 28–29.

3. **Myxococcus virescens** Thaxter. (Bot. Gaz., *17*, 1892, 404.)

Etymology: Latin *virescens*, becoming green.

Swarm stage (pseudoplasmodium): Rod masses greenish-yellow. Rods slender, irregularly curved, 0.4 by 3 to 7 microns. When cultivated in potato agar tends to lose its green color and becomes yellowish. Badian (1930) reports the presence of a dumb-bell-shaped nuclear structure which splits longitudinally in cell division, and shows autogamy preceding and a reduction division during spore formation.

Fruiting body: Spherical or conical, usually less rounded than other species of the genus, yellowish, occasionally greenish, in culture on artificial media, easily becoming white, 150 to 500 microns. The slime deliquesces in continued moisture. Spores large, about 2 microns.

Source and habitat: Thaxter (*loc. cit.*), on hen's and dog's dung, New England. Jahn (1924, *loc. cit.*), not very abundant on dung of rabbit, horse, stag and black cock. Krzemieniewski (1927, *loc. cit.*), common in soil in Poland. Badian (*loc. cit.*), Poland.

Illustrations: Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, Pl. I, Fig. 9. Badian, Acta Soc. Bot. Poloniae, *7*, 1930, 55, Pl. 1, 8 figures.

4. **Myxococcus xanthus** Beebe. (Jour. Bact., *42*, 1941, 193.)

Etymology: Greek *xanthos*, orange, golden.

Fruiting body: Spherical to subspherical, usually sessile but occasionally constricted at the base giving the appearance of a short stalk or foot. Mature fruiting body up to 300 to 400 microns in diameter, often slightly flattened on top or one side. Color varies from light yellowish-orange when young to bright orange when mature; color constant, never tending toward greenish-yellow. No outer cyst wall or

limiting membrane discernible, the spores being imbedded in the slime holding the mass together. Usually single, though two or three fruiting bodies may become joined to form an irregular mass; each is attached to the substrate, however, and never bud one from another.

Spores: Spherical, with thick outer wall or membrane. Highly refractile. Stain very easily with any of the ordinary bacterial or nuclear dyes. 2.0 microns in diameter, seldom larger.

Vegetative cells: Large, flexible, single, Gram-negative rods with rounded ends. No flagella, but move on surface of solid or semi-solid substrate with a crawling or creeping motion. Vary in size from 0.5 to 1.0 by 4 to 10 microns; average 0.75 by 5 microns. More or less distinct cell wall often evident.

Vegetative colony: Characteristics vary with the substrate.

On plain 1.5 per cent agar (no nutrients added): Very thin and transparent, often hardly visible except by transmitted light. Little or no pigmentation. Surface covered with fine, more or less regularly spaced ridges causing a dull macroscopic appearance without gloss or sheen. Margin very thin and quite regular.

On rabbit dung decoction agar: Colony thicker, the surface being broken by veins or ridges radiating from the center. Thick central area often smooth and glossy while margin much the same as that on plain agar. Veins or ridges extend outward from center in loose spiral, always in clock-wise direction. Pigmentation, yellow to pale orange, confined to thicker central portion, extends part way along veins to margin.

On nutrient agar: Growth poor. Colony thick, at first heavily veined, the veins later merging to form an irregular glossy surface. Colony remains small, pigmentation usually fairly heavy; margin thick, irregular to lobate.

Physiology: Grows well on mineral salt-agar to which has been added dulcitol, inulin, cellulose, reprecipitated cellulose or starch; hydrolyzes starch; does not destroy cellulose to any appreciable extent. Best growth on suspension of killed bacterial cells in agar; suspended cells in growth area lysed. Development completely inhibited by arabinose, largely by maltose and mannose.

Source: Isolated from dried cow dung, Ames, Iowa.

Habitat: Decomposed bacterial cells in dung.

Illustrations: Beebe (*loc. cit.*) Figs. 1–28.

5. **Myxococcus stipitatus** Thaxter. (Bot. Gaz., *23*, 1897, 395.)

Etymology: From Latin *stipes*, stalk; stalked.

Swarm stage (pseudoplasmodium): Rods 0.5 to 0.7 by 2 to 7 microns or longer. Grows well on nutrient agar, but does not fruit readily.

Fruiting body: Spore mass nearly spherical, 175 microns in diameter, deliquescent, sessile on a well developed compact stalk, white to yellowish and flesh color. Spores 0.8 to 1.2 by 1.0 to 1.15 microns. Stalk 100 to 200 microns long, 30 to 50 microns wide.

Source and habitat: Thaxter (*loc. cit.*), repeatedly on dung in laboratory cultures at Cambridge, Mass., Maine, Tennessee. Krzemieniewski (1927, *loc. cit.*), common in Polish soils.

Illustrations: Thaxter (*loc. cit.*) Pl. 31, Figs. 30 to 33. Krzemieniewski, Acta Soc. Bot. Poloniae, *4*, 1926, Pl. II, Figs. 13–14.

6. **Myxococcus ovalisporus** Krzemieniewski. (Acta Soc. Bot., Pol., *4*, 1926, 15.)

Etymology: Modern Latin *ovalis*, oval, Greek *sporos*, seed. Oval spored.

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: Produces almost spherical, characteristically shortened, ovoid

spore masses of light milky yellow color. These are often raised on a poorly developed stalk. This stalk always shows some bacterial cells remaining, and in this and color is differeniated from *M. stipitatus*. From the base of the stalk or directly from the substrate one or more small fruiting bodies develop. Spores are oval, sometimes irregularly spherical, 1.3 to 1.9 by 1.0 to 1.4 microns. In culture retains its differences from *Myxococcus stipitatus*. The latter sporulates best at room temperature, but *Myxococcus ovalisporus* in an incubator (presumably at 37°C).

Source and habitat: Develops on rabbit dung (sterilized) on soil in Poland (Krzemieniewski).

Appendix: Rippel and Flehmig (Arch. f. Mikrobiol., *4*, 1933, 229) describe a new type of aerobic cellulose destroying bacteria under the new genus name of *Itersonia*. This genus includes a single species, *Itersonia ferruginea*. This organism shows similarity to those included in *Myxococcus*.

Genus II. **Chondrococcus** *Jahn.*

(Jahn, Beiträge zur botan. Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924; *Dactylocoena* Enderlein, Bakterien-Cyclogenie, Berlin, 1924, 243.)

Synonymy: A segregate from *Myxococcus* Thaxter.

Etymology: Greek *chondros*, grain and *kokkos*, ball (coccus).

Diagnosis: Spores embedded in a viscous slime which hardens. Fruiting bodies divided by joints or constrictions, often branched, usually relatively small.

Seven species are included, of which the first described by Thaxter and best described, *Chondrococcus coralloides* (Thaxter) Jahn, may be designated as the type. The first species listed by Jahn is regarded as doubtful and should not be regarded as the type for there is no evidence that Jahn ever saw the species.

Key to the species of genus **Chondrococcus.**

I. Not parasitic on fish.
  A. Erect, simple or somewhat branched fruiting bodies.
    1. Secondary fruiting bodies not produced.
      a. Fruiting bodies constricted or jointed.
        1. *Chondrococcus coralloides.*
      aa. Fruiting body simple, columnar, club- or cushion-shaped.
        b. Fruiting body thick below, lesser above.
          2. *Chondrococcus cirrhosis.*
        bb. Not as in b.
          c. Spores 1.6 to 2.0 microns in diameter.
            d. Fruiting body cushion-shaped.
              3. *Chondrococcus megalosporus.*
            dd. Fruiting body branched.
              4. *Chondrococcus macrosporus.*
          cc. Fruiting body smaller below, above club-shaped. Spores 1.0 to 1.2 microns in diameter.
            1a. *Chondrococcus coralloides* var. *clavatus.*
    2. Secondary fruiting bodies arise as bud-, finger- or coral-like growths from primary fruiting body.
      5. *Chondrococcus blasticus.*
  B. Recumbent, simple swelling or cyst heap constituting the fruiting body.

1. Cysts 60 to 170 microns, without definite envelope, in swollen brain-like arrangement.

6. *Chondrococcus cerebriformis.*

2. Cysts 30 to 35 microns, numerous, and embedded in a thick slime envelope.

1b. *Chondrococcus coralloides* var. *polycystus.*

II. Parasitic on fish.

7. *Chondrococcus columnaris.*

1. **Chondrococcus coralloides** (Thaxter) Jahn. (*Myxococcus coralloides* Thaxter, Bot. Gaz., *17*, 1892, 404; *Myxococcus digitatus* Quehl, Cent. f. Bakt., II Abt., *16*, 1906, 18 (*pro parte*); *Myxococcus clavatus* Quehl, *ibid.*; *Myxococcus polycystus* Kofler, Sitzberg. d. kais. Wiss., Wien. Mat.-Nat. Klasse, 122 Abt., 1913, 865 (*pro parte*); *Myxococcus exiguus* Kofler, *ibid.*, 867 (*pro parte*); *Chondrococcus polycystus* Krzemieniewski, Act. Soc. Bot. Poloniae, *4*, 1926, 46.)

Etymology: Greek *korallion*, coral, *eidos*, like.

Swarm stage (pseudoplasmodium): Rod masses pale pinkish, thin, rods slender, curved 4 to 7 by 0.4 microns. Readily cultivated on lichens and on potato agar.

Fruiting bodies: Very variable in shape, usually with rounded coral-like processes, recumbent or upright, sometimes with finger-like outgrowths or rounded constrictions, usually small, about 50 microns in diameter, protuberances 20 to 30 microns wide, light rose to flesh color. Spores 1 to 1.2 microns. Jahn concludes that the species segregated by Quehl and by Kofler are of varietal rank only. Krzemieniewski (1926) regards *Chondrococcus polycystus* (Kofler) Krzemieniewski as a distinct species.

Source and habitat: Thaxter (1892), uncommon in America, on lichens. Very common in Europe. Jahn (1924), relatively common. On dung of rabbit, hare, horses, deer, old bark and old lichens. Goat dung from Lapland and Italy. Kofler (1913), dung of field mice, horses, hares, goats, roe and deer. Krzemieniewski (1927), common in Polish soil.

Illustrations: Thaxter (1892, *loc. cit.*) Pl. 24, Figs. 29-33. Quehl (1906, *loc. cit.*) Pl. 1, Figs. 1 and 9. Kofler (1913, *loc. cit.*) Pl. 1, Fig. 4, Pl. 2, Fig. 9. Krzemieniewski (1926, *loc. cit.*) Pl. II, Figs. 15–18. Jahn (1924, *loc. cit.*) Fig. Y, p. 87.

1a. *Chondrococcus corralloides* var. *clavatus* varies from *Chondrococcus coralloides* in having fruiting bodies simple or branched rather than constricted or jointed.

1b. *Chondrococcus corralloides* var. *polycystus* varies from *Chondrococcus coralloides*, in having its fruiting bodies simple swellings or "cyst heaps" rather than branched, and in being recumbent rather than erect.

2. **Chondrococcus cirrhosus** (Thaxter) Jahn. (*Myxococcus cirrhosus* Thaxter, Bot. Gaz., *23*, 1897, 409; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 200.)

Etymology: Modern Latin from Greek *cirrhos*, tawny.

Swarm stage (pseudoplasmodium): Rods 0.8 by 2 to 5 microns.

Fruiting bodies: Elongate, upright, thickened below, slender above, extended to a rounded point, 50 to 100 microns long, 20 microns in diameter at base, light red to flesh-colored. Spores about 1 micron.

Source and habitat: Thaxter (*loc. cit.*), once only on grouse dung, Mass.

Illustrations: Thaxter (*loc. cit.*) Pl. 31, Figs. 25–27.

3. **Chondrococcus megalosporus Jahn. (Beiträge zur botanischen Protistologie.**

I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 86.)

Etymology: Greek *megalos*, large; *sporos*, seed, spore; large spored.

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: About 80 to 160 microns wide, rounded, cushion-shaped, dark flesh color. Spores 2 microns.

Source and habitat: Jahn (*loc. cit.*), on stag dung near Berlin.

Illustrations: Jahn (*loc. cit.*) Fig. Y, i to k, p. 87.

4. **Chondrococcus macrosporus** Krzemieniewski. (Acta Soc. Bot. Poloniae, *4*, 1926). According to Krzemieniewski, not to be confused with Zukal's species, *Myxococcus macrosporus* (Ber. d. deutsch Bot. Gesellsch., *15*, 1897, 542.)

Etymology: Greek *makros*, long, large; *sporos*, seed, spore; large-spored.

Swarm stage (pseudoplasmodium): Not described.

Fruiting bodies: Much like *Chondrococcus coralloides*, differing in color and in size of spores. Spores 1.6 to 2.0 microns. Fruiting body yellow or light brown color, with long branches.

Source and habitat: Krzemieniewski (*loc. cit.*), found it first on leaves, later isolated from soil on rabbit dung.

Illustrations: Krzemieniewski (*loc. cit.*) Pl. II, Fig. 19.

5. **Chondrococcus blasticus** Beebe. (Iowa State Col. Jour. Sci., *15*, 1941, 310.)

Etymology: Greek *blastikos*, budding.

Fruiting body: Primary: Spherical to subspherical, usually sessile but occasionally with a short stalk or foot; pale pink to bright salmon pink; 300 to 600 microns in diameter. No outer wall or limiting membrane evident. Develops on sterilized rabbit dung in from 3 to 6 days at room temperature. Secondary: Arising as bud-like growth from the primary fruiting body. Develops into irregularly shaped, finger-, coral- or bud-like protuberance. Seldom branched; occasionally stalked but usually sessile on primary fruiting body until latter is utilized in formation of several secondary fruiting bodies. Deep pink to salmon pink in color. Variable in size and shape; 50 to 150 by 75 to 225 microns. No outer wall or limiting membrane evident.

Spores: Spherical, thick-walled, highly refractile; 1.2 to 1.4 microns in diameter. Held together in the fruiting body by the mass of slime.

Vegetative cells: Long, slender, flexible rods, straight or curved to bent, ends rounded to slightly tapered, Gram-negative. 0.5 to 0.6 by 3.0 to 5.0 microns. Usually found in groups of 2 to 12 lying parallel on the surface of the slimy colony, the group moving as a unit. Motile by a crawling or creeping motion, no flagella.

Vegetative colony: Thin, colorless, transparent at margin; surface broken by many small ridges or veins. Center smooth, slightly thicker, often showing pale pink color. Fruiting bodies first form at or near center, later distributed irregularly on other parts of colony. Margin composed of active vegetative cells.

Physiology: Good growth on mineral salt agar to which has been added such complex carbohydrates as dulcitol, inulin, cellulose, reprecipitated cellulose or starch; starch hydrolyzed, cellulose not destroyed appreciably. Can utilize agar as both C and N sources. Best growth on suspensions of killed bacterial cells in agar. Growth inhibited partially or entirely by arabinose, mannose and maltose.

Source: Goat dung and soil, Ames, Iowa.

Habitat: Soil. Decomposes organic matter, especially bacterial cells in dung.

Illustrations: Beebe (*loc. cit.*) Pl. II, Figs. 5–6, pl. IV, Fig. 18.

6. **Chondrococcus cerebriformis** (Kofler) Jahn. (*Myxococcus cerebriformis* Kofler, Sitzber. d. kais. Akad. Wiss., Wien. Math.-Nat. Klasse, 122

Abt., 1913, 866; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 86.)

Etymology: Latin *cerebrum*, brain; *formis*, shape.

Swarm stage (pseudoplasmodium): Rods 4 to 12 microns.

Fruiting bodies: About 1 mm long, clumped masses with swollen upper surface, brain-like, violet rose, often lead-gray. Cysts 100 to 170 microns, without slime envelope. Spores 1.1 to 1.6 microns. Jahn (*loc. cit.*) suggests that this may be *Archangium gephyra*.

Source and habitat: Kofler (*loc. cit.*), on hare dung in the vicinity of Vienna.

Illustrations: Kofler (*loc. cit.*) Pl. 2, Figs. 7 and 8.

7. **Chondrococcus columnaris** (Davis) Ordaland Rucker. (*Bacillus columnaris* Davis, Bull. U. S. Bur. Fisheries, *38*, 1923, 261; Ordal and Rucker, Proc. Soc. Exper. Biol. and Med., *56*, 1944, 18; also see Fish and Rucker, Trans. Amer. Fish. Soc., *73*, 1944 in press; *Cytophaga columnaris* Garnjobst, Jour. Bact., *49*, 1945, 113.)

Etymology: From Latin *columnaris*, rising in the form of a pillar.

Vegetative cells: Flexible, weakly refractive, Gram-negative rods, 0.5 to 0.7 by 4 to 8 microns. Creeping motion observed on solid media, and flexing movements in liquids.

Spores (microcysts): 0.7 to 1.2 microns, spherical to ellipsoidal, occurring on both liquid and solid media.

Physiology: Growth best on 0.5 to 0.9 per cent agar with 0.25 to 0.50 per cent Bactotryptone at pH 7.3. Colonies on tryptone agar yellow, flat and irregular. Edge uneven with swarming apparent. Gelatin liquefied rapidly. No indole. No reduction of nitrates. Starch, cellulose and agar not attacked. Sugars not fermented, but glucose oxidized.

Fruiting bodies on agar not deliquescent, and surrounded by a firm membrane. A peculiar type of fruiting body formed in liquid media. Where organisms are in contact with infected tissues or with scales, produce columnar, sometimes branched, fruiting bodies in which typical spores (microcysts) develop in 7 to 10 days.

Source and habitat: First described as cause of bacterial disease of warm water fishes (Davis, *loc. cit.*) and later in fingerlings of the cold water blue black salmon (*Oncorrhynchus nerka*). Transmissible to salmonid fishes.

Genus III. **Angiococcus** *Jahn.*

(Beiträge zur Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 89.)

A segregate from *Myxococcus* Thaxter.

Diagnosis: Fruiting body consisting of numerous round (disk-shaped) cysts, cyst wall thin, spores within.

Etymology: Greek *angion*, vessel and *kokkos*, coccus (ball).

The type species is *Angiococcus disciformis* (Thaxter) Jahn.

Key to the species of genus **Angiococcus.**

A. Cysts yellow to dark orange-yellow; disk-shaped; 35 microns in diameter
1. *Angiococcus disciformis.*

B. Cysts colorless to yellow; round; up to 15 microns in diameter.
2. *Angiococcus cellulosum.*

1. **Angiococcus disciformis** (Thaxter) Jahn. (*Myxococcus disciformis* Thaxter, Bot., Gaz., *37*, 1904, 412; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 89.)

Etymology: Greek *diskos*, a quoit, discus; Latin *formis*, shape.

Swarm stage (pseudoplasmodium): Rods 0.5 to 0.6 by 2 to 3 microns.

Fruiting bodies: Cysts disk-shaped, crowded, sessile, attached by a more or less ragged scar-like insertion, or in masses. Cysts yellowish when young, when old dark orange-yellow, about 35 by 10 microns. Cyst wall distinct, thin, becoming very slightly wrinkled. Spores irregularly spherical, embedded in viscous slime, difficult to see in the ripe cyst.

Source and habitat: Thaxter (*loc. cit.*), dung of muskrat and deer, Massachusetts and New Hampshire. Krzemieniewski (1927, *loc. cit.*), rare in Polish soils.

Illustrations: Thaxter (*loc. cit.*) Pl. 27, Figs. 19–21. Krzemieniewski Acta Soc. Bot. Poloniae, *4*, 1926, Pl. II, Figs. 21–22.

2. **Angiococcus cellulosum** Mishustin. (Microbiology, Moscow, 7, 1938, 427.)

Etymology: Modern Latin *cellulosum*, cellulose.

Fruiting body: Regularly rounded (less frequently extended or angular), 20 to 150 microns in diameter; yellow or pink in color, to drabbish when old. Encysted cells surrounded by a colorless cyst wall or envelope. Usually 1 to 3 short stalks or cystophores up to 10 microns high. Within outer wall are numerous cysts containing resting cells (spores). Cysts have regularly rounded form; unpigmented to yellow; 5 to 15 microns in diameter, average 6 microns. Number of cysts in fruiting body increases with age.

Spores: Cocci (term used is shortened rods) combined into globular aggregations easily broken up. Size not given.

Vegetative cells: 0.4 to 0.5 by 1.5 to 2.0 microns. Cell contents pigmented gray, and of indefinite outline (?).

Vegetative colony: Fairly rapid growth on cellulose with silica gel. Colony has a yellowish cast. Reaches diameter of 1.5 to 2.0 cm after 6 days with center yellowish-pink and margin tinged light pink. Surface moist. Fruiting bodies more numerous at center, but distributed over entire area. Fruiting bodies do not noticeably protrude above the surface of the colony.

Physiology: Cellulose attacked but not completely destroyed. Lower fibers remain intact, but on treatment with hot soda solution they fall spart.

Habitat: Soils.

Genus IV. **Sporocytophaga** *Stanier.*

(Jour. Bact., *40*, 1940, 629.)

Diagnosis: Spherical or ellipsoidal microcysts formed loosely in masses of slime among the vegetative cells. Fruiting bodies absent.

Etymology: Greek *sporos* seed, spore; *kytos* hollow place, cell and *phagein* to eat.

The type species is *Sporocytophaga myxococcoides* (Krzemieniewska) Stanier.

Key to the species of genus **Sporocytophaga.**

I. Microcysts spherical.
  A. Does not utilize starch.
    1. *Sporocytophaga myxococcoides.*
  B. Utilizes starch.
    2. *Sporocytophaga congregata.*

II. Microcysts ellipsoidal.
    3. *Sporocytophaga ellipsospora.*

1. **Sporocytophaga myxococcoides** (Krzemieniewska Stanier. (*Spirochaeta cytophaga* Hutchinson and Clayton, Jour. Agr. Sci., *9*, 1919, 150; *Cytophaga myxococcoides* Krzemieniewska, Arch. Mikrobiol., *4*, 1933, 400; *Cytophaga globulosa* Stapp and Bortels, Cent. f. Bakt., II Abt., *90*, 1934, 47; *Cytophaga hutchinsonii* Imšenecki and Solntzeva, Bull. Acad. Sci. U.S.S.R., Ser. Biol., No. 6, 1936, 1129; not *Cytophaga hutchinsoni* Winogradsky, Ann. Inst. Pasteur, *43*, 1929, 578; Stanier, Jour. Bact., *40*, 1940, 630.)

Etymology: Modern Latin from generic name *Myxococcus*, and *eidos*, like.

Vegetative morphology: Flexible, singly occurring rods, 0.3 to 0.4 micron wide at the center, tapering to both ends. Length 3 to 8 microns according to Krzemieniewska (*loc. cit.*), 2.5 to 5 microns according to Jensen (Proc. Linn. Soc. N. So. Wales, *65*, 1940, 547). May be straight, bent, U-shaped or S-shaped. Show creeping motility (Stapp and Bortels, *loc. cit.*). Stain poorly with ordinary aniline dyes; with Giemsa's stain, the young cells are colored uniformly except for the tips. As the rods shorten and swell to form microcysts, the chromatin becomes concentrated and moves toward the center of the cell, generally in the form of two parallel bands (Krzemieniewska, Acta Soc. Bot. Pol., 7, 1930, 514).

Microcysts: Spherical, 1.3 to 1.6 microns in diameter, covered with a sheath of mucus. According to Krzemieniewska (1930, *loc. cit.*), germination is by emergence of the shortened rod from the sheath, followed by elongation; according to Stapp and Bortels (*loc. cit.*) and Imšenecki and Solntzeva (*loc. cit.*), by a simple elongation of the entire microcyst.

Growth is strictly confined to cellulose. On mineral salts-silica gel plates covered with filter paper, yellow, glistening, slightly mucilaginous patches are produced after a few days. The color gradually assumes a light brownish tinge on aging. The filter paper in these regions is eventually completely dissolved and the patches become translucent.

Ammonia, nitrate, asparagin, aspartic acid and peptone can serve as sources of nitrogen (Jensen, *loc. cit.*).

Strictly aerobic.

Optimum temperature 28 to 30°C.

Source: Isolated from soil.

Habitat: Soil. Decomposes cellulose.

2. **Sporocytophaga congregata** Fuller and Norman. (Jour. Bact., *45*, 1943, 567.)

Etymology: Latin *congrēgo*, to assemble.

Vegetative cells are long, flexuous rods with pointed ends, 0.5 to 0.7 by 5.5 to 8.0 microns. Creeping motility on solid surfaces.

Spores (microcysts): Spherical, 0.7 to 1.1 microns in diameter. Usually occur in localized regions within the colony.

Growth on starch agar is smoky, later turning yellow. Colonies are irregularly round, slightly concave. Edge is smooth and entire at first, later becoming irregular. Marginal and internal swarming may be prominent. The vegetative cells gather into groups and in these regions a large number of spherical spores are found.

Growth on cellulose dextrin agar is pale; colonies are small and concave. Hollowing of the agar is limited to the area of colony growth.

Glucose, galactose, lactose, maltose, sucrose, arabinose, calcium gluconate, starch, cellulose dextrin, pectin, and hemicellulose are utilized. Filter paper is not attacked.

Ammonium, nitrate, and peptone are suitable nitrogen sources.

Indole not formed.

Nitrites not produced from nitrates.

Litmus milk: Growth but no digestion or curd formation.

Highly aerobic.

Optimum temperature 25° to 30°C.

Source: Isolated from soil.

Habitat: Soil. Decomposes organic matter.

3. **Sporocytophaga ellipsospora** (Imšenecki and Solntzeva) Stanier. (*Cytophaga ellipsospora* Imšenecki and Solntzeva, Bull. Acad. Sci. U.S.S.R., Ser. Biol., No. 6, 1936, 1137; Stanier, Bact. Rev., *6*, 1942, 153 and 190.)

Etymology: Greek *ellipsis*, an ellipse, and *sporos*, seed.

Vegetative morphology: Flexible, singly occurring rods, 0.4 micron wide at the center and tapering to both ends. Length 7.5 microns. May be straight, bent, U-shaped, or S-shaped. Show creeping motility.

Microcysts: Oval or somewhat elongated, 0.9 to 1.2 by 1.6 to 1.8 microns Almost always situated in closely-packed aggregates, isolated individual microcysts rare. Germinate by elongation.

Growth is strictly confined to cellulose. On mineral salts-silica gel plates covered with filter paper, orange, glistening, mucilaginous patches are produced. Ultimately the filter paper is completely dissolved and the patches become translucent.

Ammonia, nitrate and peptone can serve as sources of nitrogen.

Strictly aerobic.

Optimum temperature 28° to 30°C.

Source: Isolated from soil.

Habitat: Soil. Decomposes cellulose

ORDER V. SPIROCHAETALES BUCHANAN.*

(Jour. Bact., *3*, 1918, 542.)

Slender, flexuous cell body in the form of a spiral with at least one complete turn, 6 to 500 microns in length. Some forms may show an axial filament, a lateral crista or ridge, or transverse striations; otherwise no significant protoplasmic pattern. Smaller forms may have a lower refractive index than bacteria, and so living organisms can be seen only with dark field illumination. Some forms take aniline dyes with difficulty. Giemsa's stain is uniformly successful. Multiplication by transverse fission. No sexual cycle known. Granules formed by some species in vector hosts. All forms are motile. No organs of locomotion**; motility serpentine or by spinning on the long axis without polarity. Free-living, saprophytic and parasitic.

Key to the families of order **Spirochaetales.**

I. Spirals 30 to 500 microns in length, having definite protoplasmic structures.
Family I. *Spirochaetaceae*, p. 1051.
II. Spirals 4 to 16 microns in length, having no obvious protoplasmic structure.
Family II. *Treponemataceae*, p. 1058.

FAMILY I. SPIROCHAETACEAE SWELLENGREBEL.

(Ann. Inst. Past., *21*, 1907, 581.)

Coarse spiral organisms, 30 to 500 microns in length, having definite protoplasmic structures. Found in stagnant, fresh or salt water and in the intestinal tract of bivalve molluscs (*Lamellibranchiata*).

Key to the genera of family **Spirochaetaceae.**

I. No obvious periplast membrane and no cross-striations.
Genus I. *Spirochaeta*, p. 1051.
II. Periplast membrane present. Cross-striations prominent in stained specimens.
A. Free-living in marine ooze.
Genus II. *Saprospira*, p. 1054.
B. Parasitic on lamellibranch molluscs. Crista prominent.
Genus III. *Cristispira*, p. 1055.

Genus I. Spirochaeta *Ehrenberg.*

(Ehrenberg, Abhandl. Berl. Akad., 1833, 313; *Spirochoeta* Dujardin, Hist. nat. des Zoophytes, 1841, 209; *Spirochaete* Cohn, Beitr. z. Biol. d. Pflanz., *1*, Heft 1, 1872,

* Originally prepared by Prof. D. H. Bergey, Philadelphia, Pa., October, 1922. Revised by Prof. E. G. D. Murray, McGill University, Montreal, P. Q., Canada, December, 1938. Further revision by Dr. G. H. Robinson, Wm. H. Singer Memorial Research Laboratory of the Allegheny General Hospital, Pittsburgh, Pa., September, 1943. Appendices prepared by Mrs. Eleanore Heist Clise, Geneva, N. Y., September, 1943.

** Recent photographs taken with the electron microscope indicate the presence of structures resembling flagella (Mudd, Polevitzky and Anderson, Jour. Bact., *46*, 1943, 15). Whether these can be considered as organs of locomotion awaits decision. At present it seems best to confine descriptions of structure to features seen by use of the oil immersion lens.

180; *Ehrenbergia* Gieszczykiewicz, Bull. Acad. Polonaise d. Sci. et Lettres, Cl. Sci. Math. et Nat., Sér. B, 1939, 24.)

Non-parasitic, with flexible, undulating body and with or without flagelliform tapering ends. Protoplast wound spirally around a well-defined axial filament. No obvious periplast membrane and no cross-striations. Motility by a creeping motion. Primary spiral permanent. Free-living in fresh or sea water slime, especially in the presence of H_2S. Common in sewage and foul waters.

The type species is *Spirochaeta plicatilis* Ehrenberg.

Key to the species of genus **Spirochaeta.**

I. Large spirals with rounded ends.
   1. *Spirochaeta plicatilis.*
   2. *Spirochaeta marina.*
   3. *Spirochaeta eurystrepta.*

II. Smaller spirals with pointed ends.
   4. *Spirochaeta stenostrepta.*
   5. *Spirochaeta daxensis.*

1. **Spirochaeta plicatilis** Ehrenberg. (Ehrenberg, Die Infusionstierchen, 1838, 83; *Spirillum plicatile* Dujardin, Infus., *1*, 1841, 225; *Spirulina plicatilis* Cohn, Nova Acta Acad. Caes. Leop. Carol., *24*, I, 1853, 125; *Spirochaete plicatilis* Cohn, Beitr. z. Biol. d. Pflanz., *1*, Heft 2, 1872, 180; *Spirillum portae* Mantegazza, Giorn. Ist. Lomb., *3*, p. 487, according to DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1006; *Spirochaeta plicatilis plicatilis* Zuelzer, Arch. f. Protistenk., *24*, 1912, 17; *Ehrenbergia plicatilis* Gieszczykiewicz, Bull. Acad. Polonaise d. Sci. et Lettres, Cl. Sci. Math. et Nat., Sér. B, 1939, 24.) From Latin, folded.

Cylindrical: 0.5 to 0.75 by 100 to 500 microns, with blunt ends.

Spiral amplitude: 2.0 microns, regular. Spiral depth: 1.5 microns, regular. Waves, several, large, inconstant, irregular.

Axial filament distinct in stained specimens, consisting of chitin or cutin-like substance. Flexible, elastic.

Division transverse.

Stains violet by Giemsa's stain and gray by iron-hemotoxylin.

Cytoplasmic spirals stain with eosin, rubin, etc. Contain volutin granules.

Trypsin digestion: Axial filament resistant.

Bile salts (10 per cent): Becomes shadowy, pale, but is not dissolved.

Saponin (10 per cent): Lives 30 minutes. Later becomes shadowy, but is not dissolved.

Grows best under low oxygen tension.

Optimum temperature 20° to 25°C.

Habitat: Free-living in fresh or salt water.

2. **Spirochaeta marina** Zuelzer. (*Spirochaeta plicatilis marina* Zuelzer, Arch. f. Protistenk., *24*, 1912, 17; Zuelzer, *ibid.*, 51.) From Latin, of the sea.

Probably a subspecies or variant of *Spirochaeta plicatilis.*

Cylindrical, 0.5 by 100 to 200 microns with blunt ends.

Axial filament present. Flexible, elastic.

Division transverse.

Contains smaller and more irregularly distributed volutin granules than *Spirochaeta plicatilis.* Cytoplasmic spirals stain.

Grows best at low oxygen tension.

Optimum temperature 20°C.

Habitat: Sea water.

3. **Spirochaeta eurystrepta** Zuelzer. (*Spirochaeta plicatilis eurystrepta* Zuelzer, Arch. f. Protistenk., *24*, 1912, 17;

Zuelzer, *ibid.*, 51.) From Greek, broadly twisted.

Probably a subspecies or variant of *Spirochaeta plicatilis.*

Cylindrical: 0.5 micron in thickness and up to 300 microns in length.

Spiral amplitude: More shallow than spirals of *Spirochaeta plicatilis* with blunt ends.

Axial filament present. Flexible, elastic.

Division transverse.

Fewer volutin granules than in *Spirochaeta plicatilis.* Cytoplasmic spirals stain.

Optimum temperature 20°C.

Habitat: Swamp water and in grossly polluted water containing H_2S.

4. **Spirochaeta stenostrepta** Zuelzer. (Zuelzer, Arch. f. Protistenkunde, *24*, 1912, 16; *Treponema stenostrepta* Enderlein, Bakterien-Cyclogenie, 1925, 253.) From Greek, narrowly twisted.

Cylindrical: 0.25 micron in thickness and 20 to 60, occasionally up to 200, microns in length, with pointed ends.

Spiral amplitude very narrow with steep windings.

Axial filament present. Flexible, elastic.

Division transverse.

Fewer volutin granules than in *Spirochaeta plicatilis.*

Cytoplasmic spirals stain.

Optimum temperature 20°C.

Habitat: Water containing H_2S.

5. **Spirochaeta daxensis** Cantacuzène. (Compt. rend. Soc. Biol., Paris, *68*, 1910, 75.) Named for Dax, a watering place in France.

Large spirals: 0.5 to 2.5 by 30 to 100 microns, possessing a longitudinal chromatin filament, and tapering at the ends.

They are flattened and exhibit a double series of curls, smaller waves being superimposed on larger undulations.

Optimum temperature 44° to 52°C.

Source: Found in water of hot spring of Dax (52° to 56°C).

Habitat: Hot springs.

Appendix: The following species may belong in this genus. Descriptions are usually inadequate.

Spirochaeta agilis Adelmann. (Cent. f. Bakt., I Abt., Orig., *88*, 1922, 413.) From mud from the harbor at Kiel. Original culture had a weak odor of hydrogen sulfide.

Spirochaeta aurantia Vinzent. (Compt. rend. Soc. Biol., Paris, *95*, 1926, 1472.) From drain water. Forms small yellowish-orange colonies on agar after 5 to 8 days. Shows involution forms. This species definitely does not belong in the genus *Spirochaeta*, although it is placed here for the present. Its description suggests that it may belong among the vibrios.

Spirochaeta flexibilis Nägler. (Cent. f. Bakt., I Abt., Orig., *50*, 1909, 445.) From the mud of a lake.

Spirochaeta fulgurans Dobell. (Arch. f. Protistenk., *26*, 1912, 117.) From water of the river Granta at Cambridge. May be a synonym of *Spirochaeta stenostrepta.*

Spirochaeta gigantea Warming. (Warming, Videnskabl. Meddel. Naturh. Foren., Copenhagen, 1875, 70; *Spirillum giganteum* Trevisan, I generi e le specie delle Batteriacee, 1889, 24; not *Spirillum giganteum* Migula, Syst. d. Bakt., *2*, 1900, 1025.) Large, 3 microns in diameter. Inadequately described and possibly not a spirochaete.

Spirochaeta graminea Zuelzer. (Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1670.) From an infusion of herbs. Size 0.25 by 100 microns. From rivers and marshes where it digests cellulose.

Spirochaeta graminea marina Zuelzer. (Cent. f. Bakt., I Abt., Orig., *96*, 1925, 426.) From sea water.

Spirochaeta icterogenes marina Zuelzer.

(Cent. f. Bakt., I Abt., Orig., *96*, 1925, 426.) From sea water.

Spirochaeta minima Dobell. (Dobell, Arch. f. Protistenk., *26*, 1912, 117; not *Spirochaeta minima* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 187 (*Treponema minimum* Beaurepaire-Aragão and Vianna, Mem. Inst. Oswaldo Cruz, *5*, 1913, 211).) One of the smallest known *Spirochaeta*, 0.5 by 2.0 to 2.5 microns. From water of the river Granta at Cambridge. Similar to *Spirochaeta fulgurans*.

Spirochaeta vivax (Dobell) Zuelzer. (*Treponema vivax* Dobell, Arch. f. Protistenk., *26*, 1912, 117; Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1669.) From fresh water of the river Granta at Cambridge.

Spirochaete kochii Trevisan. (Spirochaete des Wollsteiner See, Koch, in Cohn, Beitr. z. Biol. d. Pflanzen, *2*, Heft 3, 1877, 420; Trevisan, Batter. Ital., 1879, 26; *Spirillum kochii* Trevisan, I generi e le specie delle Batteriacee, 1889, 24.) From water.

Spirochaete schroeteri Cohn. (Jahresber. d. Schles. Gesellch. f. 1883, 198; quoted from Schroeter, in Cohn, Kryptog. Flora v. Schlesien, *3*, 1, 1889, 168; *Spirillum schroeteri* Cohn, quoted from DeToni and Trevisan, in Saccardo, Sylloge Fungorum, *8*, 1889, 1007.) Similar to *Spirochaete cohnii*. From cellar walls.

Genus II. Saprospira *Gross.*

(Mittheil. Zool. Stat. zu Neapel, *20*, 1911, 190.)

Spiral protoplasm without evident axial filament. Spirals rather shallow. Transverse markings or septa (?) seen in unstained and stained specimens. Periplast membrane distinct. Motility active and rotating. Free-living in marine ooze.

The type species is *Saprospira grandis* Gross.

1. **Saprospira grandis** Gross. (Mitteil. Zool. Station zu Neapel, *20*, 1911, 190.) From Latin, great.

Cylindrical, 1.2 by 80 microns in length, with obtuse ends.

Spiral amplitude is 24 microns.

Waves large, inconstant, shallow, irregular, 3 to 5 in number, sometimes almost straight.

Axial filament absent.

Cross-striations present.

Membrane distinct.

Division transverse.

Flexible, elastic.

Crista absent.

Terminal spiral filament absent.

Highly motile end portion absent.

Trypsin digestion.

Source: Found in intestinal tract of the oyster.

Habitat: Free-living in foraminiferous sand.

2. **Saprospira puncta** Dimitroff. (Jour. Bact., *12*, 1926, 146.) From Latin, pitted.

Large spirals: 1.0 by 86 microns with pointed ends.

The spiral amplitude is 4 to 8 microns.

The average number of turns is 3.

Axial filament absent.

Cross-striations present.

Membrane distinct.

Division transverse.

Source: Found in oysters.

3. **Saprospira lepta** Dimitroff. (Jour. Bact., *12*, 1926, 144.) From Latin, small.

Large spirals: 0.5 by 70.0 microns, with pointed ends.

The spiral amplitude ranges from 5 to 13 microns.

The spiral width varies from 1.6 to 4.8 microns.

The average number of turns is 6.

Axial filament absent.

Cross-striations present.

Membrane distinct.

Division transverse.

Source: Found in oysters in Baltimore, Maryland.

Appendix: The following species have been placed in this genus.

Saprospira flexuosa Dobell. (Arch. f. Protistenk., *26*, 1912, 117.) Isolated once from water of the river Granta at Cambridge.

Saprospira nana Gross. (Mittheil. Zool. Sta. zu Neapel, *20*, 1911, 188.) From foraminiferous sand.

Genus III. Cristispira *Gross.*

(Mittheil. Zool. Stat. zu Neapel, *20*, 1910, 41.)

Flexuous cell bodies in coarse spirals, 28 to 120 microns in length. Characterized by a crista or thin membrane of varying prominence on one side of the body extending the entire length of the organism. Cross-striations. Actively motile. Found in the intestinal tract of molluscs.

The type species is *Cristispira balbianii* (Certes) Gross.

1. **Cristispira balbianii** (Certes) Gross. (*Trypanosoma balbianii* Certes, Bull. Soc. Zool. de France, *7*, 1882, 347; *Spirochaeta balbianii* Swellengrebel, Ann. Inst. Past., *21*, 1907, 562; *Spirochaete balbianii* Borrel and Cernovodeanu, Compt. rend. Soc. Biol., Paris, *62*, 1907, 1102; Gross, Cent. f. Bakt., I Abt., Orig., *65*, 1912, 90.)

Cylindrical: 1.0 to 3.0 by 40 to 120 microns, with obtuse ends.

Spiral amplitude is 8 microns. Spiral depth is 1.6 microns. Waves 2 to 5, sometimes more, large, irregular, shallow.

Axial filament absent.

Cross-striations present.

Membrane distinct.

Flexible, elastic.

Crista present, a ridge-like membrane making one to two complete turns.

Terminal spiral filament absent. Highly motile end portion absent.

Stains: Cell membrane behaves like chitin or cutin substance. Stains violet by Giemsa's solution, and light gray by iron-hemotoxylin.

Trypsin digestion: Membrane resistant, crista and striations disappear.

Bile salt (10 per cent): Crista quickly dissolves.

Saponin (10 per cent): Crista becomes fibrillar, then indistinct.

Source: From the crystalline style of oysters.

Habitat: Parasitic in alimentary tract of shell-fish.

2. **Cristispira anodontae** (Keysselitz) Gross. (*Spirochaeta anodontae* Keysselitz, Arb. a. d. kaiserl. Gesundheitsamte, *23*, 1906, 566; Gross, Cent. f. Bakt., I Abt., Orig., *65*, 1912, 900.) From M.L., mussels.

0.8 to 1.2 by 44 to 88 microns with sharply pointed ends; flattened and possessing an undulating membrane. The periplast is fibrillar in appearance and there is a dark granule at each end of the undulating membrane. The chromatin material is distributed in the form of globules or elongated bands.

Large spirals: The average width of the spiral is 2 microns. The average wave length is 8 microns.

The number of complete turns ranges from 5 to 11.

Habitat: Found in the crystalline style of fresh water mussels, *Anodonta cygnea* and *A. mutabilis*, also in intestinal tract of oysters.

3. **Cristispira pinnae** (Gonder) Bergey et al. (*Spirochaete pinnae* Gonder, Cent. f. Bakt., I Abt., Orig., *47*, 1908, 491; *Spirochaeta pinnae* Schellack, Arb. a. d.

kaiserl. Gesundheitsamte, *30*, 1909, 379; Bergey et al., Manual, 1st ed., 1923, 423.) From Latin, of a mussel.

Spirals: 0.5 to 3.0 by 10 to 60 microns, round in section with blunt ends, the one being slightly more pointed than the other.

They have a ridge or comb running along one side but no terminal filaments.

Cross-striations distinct.

The chromatin granules are grouped in fours.

An undulating membrane can be demonstrated.

Source: Found in the intestinal canal of the scallop (*Pecten jacobaeus*).

Habitat: From the crystalline style of molluscs.

Appendix: Additional species which appear to belong in this genus are:

Cristispira acuminata (Schellack) Ford. (*Spirochaeta acuminata* Schellack, Arb. kais. Gesundheitsamte, *30*, 1909, 379; not *Spirochaeta acuminata* Castellani, Brit. Med. Jour., *2*, 1905, 1330; Ford, Textb. of Bact., 1927, 939.) From the crystalline style of a mollusc, *Tapes laeta*.

Cristispira cardii-papillosi (Schellack) Ford. (*Spirochaeta cardii-papillosi* Schellack, Arb. kais. Gesundheitsamte, *30*, 1909, 379; Ford, Textb. of Bact., 1927, 939.) From the crystalline style of a mollusc, *Cardium papillosum*.

Cristispira chamae (Schellack) Noguchi. (*Spirochaeta chamae* Schellack, Arb. kais. Gesundheitsamte, *30*, 1909, 379; Noguchi, Jour. Exp. Med., *27*, 1918, 583.) From the crystalline styles of molluscs, *Chama spp.*

Cristispira gastrochaenae (Schellack) Ford. (*Spirochaeta gastrochaenae* Schellack, Arb. kais. Gesundheitsamte, *30*, 1909, 379; Ford, Textb. of Bact., 1927, 940.) From a shellfish, *Gastrochaena dubia*. Constant length 29 microns.

Cristispira helgolandica Collier. (Cent. f. Bakt., I Abt., Orig., *86*, 1921, 132.) Found three times in the body fluid of an echinoderm, *Asterias rubens*, in the North sea. Average length 68 microns. Named for the place where the investigation was made (Helgoland).

Cristispira interrogationis Gross. (Mittheil. Zool. Station zu Neapel, *20*, 1910, 41.) From the intestinal canal of the scallop, *Pecten jacobaeus*.

Cristispira limae (Schellack) Ford. (*Spirochaeta limae* Schellack, Arb. kais. Gesundheitsamte, *30*, 1909, 379; Ford, Textb. of Bact., 1927, 939.) From the crystalline styles of molluscs, *Lima spp.* Similar to *Cristispira balbianii*.

Cristispira mactrae (Prowazek) Ford. (*Spirochaeta mactrae* Prowazek, Arch. f. Schiffs- u. Tropenhyg., *14*, 1910, 297; Ford, Textb. of Bact., 1927, 940.) From the digestive tract of a shellfish, *Mactra sulcataria*.

Cristispira mina Dimitroff. (Jour. Bact., *12*, 1926, 159.) Found in oysters.

Cristispira modiolae (Schellack) Noguchi. (*Spirochaeta modiolae* Schellack, Arb. kais. Gesundheitsamte, *30*, 1909, 379; Noguchi, Jour. Exp. Med., *27*, 1918, 583.) Found in mussels and oysters.

Cristispira ostreae (Schellack) Noguchi. (*Spirochaeta ostreae* Schellack, Arb. kais. Gesundheitsamte, *30*, 1909, 379; Noguchi, Jour. Exp. Med., *27*, 1918, 583.) From the crystalline style of the oyster, *Ostrea edulis*. Identical with *Cristispira anodontae* Gross.

Cristispira pachelabrae de Mello. (Compt. rend. Soc. Biol., Paris, *84*, 1921, 241.) From the digestive tract of a shellfish, *Pachelabra moestra*.

Cristispira parvula Dobell. (Arch. f. Protistenk., *26*, 1912, 117.) From the crystalline style of a mollusc, *Venus (Meretrix) castra*, in Ceylon. The smallest *Cristispira* known—0.4 to 0.5 by 20 to 45 microns.

Cristispira pectinis Gross. (Mittheil. Zool. Sta. zu Neapel, *20*, 1910, 41.) From the digestive tract of a scallop, *Pecten jacobaeus*. Identical with *Cristispira balbianii* Gross.

Cristispira polydorae Mesnil and Caul-

lery. (Compt. rend. Soc. Biol., Paris, *79*, 1916, 1118; *Cristispirella polydorae* Hollande, Compt. rend. Acad. Sci. Paris, *172*, 1921, 1696). From a marine annelid, *Polydora flava*.

Cristispira pusilla (Schellack) Ford. (*Spirochaeta pusilla* Schellack, Arb. kais. Gesundheitsamte, *30*, 1909, 379; Ford, Textb. of Bact., 1927, 940.) From the digestive tract of a mussel, *Anodonta mutabilis*.

Cristispira saxicavae (Schellack) Ford. (*Spirochaeta saxicavae* Schellack, Arb. kais. Gesundheitsamte, *30*, 1909, 379; Ford, Textb. of Bact., 1927, 940.) From the crystalline style of a mollusc, *Saxicava arctica*.

Cristispira spiculifera (Schellack) Dimitroff. (*Spirochaeta spiculifera* Schellack, Arb. kais. Gesundheitsamte, *30*, 1909, 379; Dimitroff, Jour. Bact., *12*, 1926, 157.) Found in mussels.

Cristispira tapetos (Schellack) Gross. (*Spirochaeta tapetos* Schellack, Arb. kais. Gesundheitsamte, *30*, 1909, 379; Gross, Cent. f. Bakt., I Abt., Orig., *65*, 1912, 84.) From the crystalline style of a mollusc, *Tapes decussata*.

Cristispira tenua Dimitroff. (Jour. Bact., *12*, 1926, 160.) Found in oysters.

Cristispira veneris Dobell. (Quart. Jour. Microsc. Sci., London, *54*, 1910–1911, 507 and *ibid.*, *56*, 1911, Part 3.) From a clam, *Venus* (*Meretrix*) *castra*, in Ceylon. Identical with *Cristispira balbianii* Gross.

Cristispirella caviae Hollande. (Compt. rend. Acad. Sci., Paris, *172*, 1921, 1693.) From the intestine of a guinea pig. Probably a protozoan. Evidently the same as *Heliconema* (see appendix to *Borrelia*). Both *Cristispirilla polydorae* and *Cristispirella caviae* have characteristics at variance with accepted ideas of spirochaetes.

Spirochaeta solenis Fantham. (Ann. Trop. Med. and Parasitol., *5*, 1911, 479.) A parasite of a mollusc, *Solen ensis*.

FAMILY II. TREPONEMATACEAE SCHAUDINN.

(Deutsche med. Wochnschr., *31*, 1905, 1728.)

Coarse or slender spirals, 4 to 16 microns in length; longer forms due to incomplete or delayed division. Protoplasm with no obvious structural features. Some may show terminal filaments. Spirals regular or irregular, flexible or comparatively rigid. Some visible only with dark field illumination. Parasitic on vertebrates with few exceptions. Some pathogenic. Many can be cultivated.

Key to the genera of family **Treponemataceae.**

I. Stains easily with ordinary aniline dyes.

Genus I. *Borrelia*, p. 1058.

II. Stain with difficulty except with Giemsa's stain and silver impregnation.

A. Strict anaerobes.

Genus II. *Treponema*, p. 1071.

B. Aerobes.

Genus III. *Leptospira*, p. 1076.

Genus I. **Borrelia*** *Swellengrebel.*

(Swellengrebel, Ann. Inst. Past., *21*, 1907, 582; *Spiroschaudinnia* Sambon, in Manson, Tropical Diseases, August, 1907, 833; *Cacospira* Enderlein, Sitzber. Ges. Naturf. Freunde, Berlin, 1917, 309; *Entomospira* Enderlein, *ibid.*; *Spironema* Bergey et al., Manual, 1st ed., 1923, 424; not *Spironema* Vuillemin, Compt. rend. Acad. Sci. Paris, *140*, 1905, 1567; *Spirochaeta* Gieszczykiewicz, Bull. Acad. Polonaise d. Sci. et Lettres, Cl. Sci. Math. et Nat., Sér. B, 1939, 24.)

Length 8 to 16 microns. Coarse, shallow, irregular, with a few obtuse angled spirals. Generally taper terminally into fine filaments. Stain easily with ordinary aniline dyes. Refractive index approximately the same as that of true bacteria. Parasitic upon many forms of animal life. Some are pathogenic for man, other mammals and birds. Generally hematophytes are found on mucous membranes. Some are transmitted by the bites of arthropods.

The type species is *Borrelia anserina* (Sakharoff) Bergey et al.

1. **Borrelia anserina** (Sakharoff) Bergey et al. (*Spirochaeta anserina* Sakharoff, Ann. Inst. Past., *5*, 1891, 564; *Spirillum anserum* (sic) Sternberg, Man. of Bact., 1893, 499; *Spirillum anserinum* Macé, Traité Pratique de Bact., 4th ed., 1901, 1060; *Spirochaete anserina* Macé, *ibid.*; *Spiroschaudinnia anserina* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 403; *Spironema anserina* Noguchi, Jour. Exp. Med., *27*, 1918, 584; Bergey et al., Manual, 2nd ed., 1925, 435; *Treponema anserina* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 456.) From Latin, pertaining to geese.

Synonyms: *Spirochaeta marchouxi* Nuttall, Epidemiol. Soc., London, *24*, 1904, 12 (Spirille de la poule, Marchoux and Salimbeni, Ann. Inst. Past., *17*, 1903, 569; *Spirochaeta gallinarum* Stephens and Christopher, Practical Study of Malaria and Other Blood Parasites, Liverpool, 1905; *Borrelia gallinarum* Swellengrebel, Ann. Inst. Past., *21*, 1907, 623; *Spirochaete gallinarum* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 623; *Spironema gallinarum* Gross, Cent. f. Bakt., I Abt., Orig., *65*, 1912, 92; *Spiroschaudinnia marchouxi* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 403; *Spironema marchouxi* Ford,

---

* Further revision of the genus by Prof. E. G. D. Murray, McGill Univ., Montreal, P. Q., Canada, April, 1947. Reviewed by Dr. Gordon E. Davis, Rocky Mountain Laboratory, U.S.P.H.S, Hamilton, Montana.

Textb. of Bact., 1927, 955; *Spirochaeta gallinae* Ford, *idem*; *Treponema gallinarum* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 461; *Treponema marchouxi* Gay et al., Agents of Disease and Host Resistance, 1935, 1077). The cause of septicaemia in chickens.

Spirochaeta granulosa penetrans Balfour, Jour. Trop. Med. and Hyg., *10*, 1907, 153 (*Spiroschaudinnia granulosa* Balfour, Jour. Trop. Veter., Calcutta, *5*, 1910, 309; *Spironema granulosa* Ford, Textb. of Bact., 1927, 957). From spirochetosis of fowls in Sudan.

Spirochaeta nicollei Brumpt, Bull. Soc. Path. Exot., *2*, 1909, 285 and/or Précis de Parasitol., Paris, 1st ed., 1910 (Galli-Valerio, Cent. f. Bakt., I Abt., Orig., *50*, 1909, 189 and *61*, 1912, 529; *Spironema nicollei* Ford, Textb. of Bact., 1927, 958; *Treponema nicollei* Gay et al., Agents of disease and Host Resistance, 1935, 1077). From spirochetosis of geese in Tunisia.

Spirochaeta neveuxi Brumpt, Bull. Soc. Path. Exot., *2*, 1909, 285 (*Spiroschaudinnia neveuxii* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 404; *Spironema neveuxi* Ford, Textb. of Bact., 1927, 958; *Treponema neveuxi* Gay et al., Agents of Disease and Host Resistance, 1935, 1077). The cause of fowl spirochetosis in Senegal.

Spirochaeta gallinarum var. *hereditaria* Neumann and Mayer, in Lehmann, Med. Atlanten, *11*, 1914, 276. A North African strain of fowl spirochetosis.

Borrelia pullorum Redowitz, Amer. Jour. Med. Technol., *2*, 1936, 91. From diseased chickens.

Spirochaeta anatis Parrot, Bull. Soc. Path. Exot., *13*, 1920, 647. Pathogenic for domestic ducks in Algeria.

Morphology: 0.25 to 0.3 by 8 to 20 microns, averaging about 1 spiral per micron.

Actively motile, with lashing movements.

Stains readily with aniline dyes and Giemsa's stain.

Cultivation: Can be cultivated in Noguchi's ascitic fluid-rabbit kidney medium.

Immunology: Antigenically distinct from species found in mammals.

Arthropod vectors: Transmitted by the bites of ticks (*Argas persicus*, *A. miniatus*, *A. reflexus* and *Ornithodoros moubata*.)

Pathogenic for birds but not for mammals.

Source: From blood of infected geese, ducks, fowls and vector ticks.

Habitat: The cause of spirochetosis of fowls.

2. **Borrelia recurrentis** (Lebert) Bergey et al. (Obermeier, Berlin. klin. Wochschr., 1873, 152; *Protomycetum recurrentis* Lebert, Ziemssen's Handbuch, *2*, 1874, 267; *Spirochaete obermeieri* Cohn, Beitr. z. Biol. d. Pflanzen, *1*, Heft 3, 1875, 196; *Spirillum obermeieri* Zopf, Die Spaltpilze, 3 Aufl., 1885, 71; *Spirochaeta obermeieri* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., *1*, 1a, 1895, 35; *Spirochaete recurrentis* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 621; *Spirochaeta recurrentis* Castellani and Chalmers, Man. Trop. Med., 1st ed., 1910, 305; *Spironema recurrentis* Gross, Cent. f. Bakt., I Abt., Orig., *65*, 1912, 85; *Spiroschaudinnia recurrentis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 398; *Spironema obermeieri* Park and Williams, Pathogenic Microorganisms, 6th ed., 1917, 513; *Cacospira recurrentis* Enderlein, Sitzungsber. d. Gesellsch. naturf. Freunde, 1917, 313; *Treponema recurrentis* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 508; *Treponema obermeieri* Brumpt, *ibid.*; *Cacospira obermeieri* Enderlein, Bakterien-Cyclogenie, 1925, 254; Bergey et al., Manual, 2nd ed., 1925, 433; *Spirillum recurrentis* Ford, Textb. of Bact., 1927, 948; *Spiroschaudinnia obermeieri* Ford, *ibid.*) From Latin, recurring.

Cylindrical or slightly flattened, 0.35 to 0.5 by 8 to 16 microns, with pointed ends.

Spiral amplitude 1.5 microns.

Spirals large, wavy, inconstant, about 5 in number.

Terminal finely spiral filaments present.

Highly motile end portion absent.

Motility: By active cork-screw motion without polarity. Lashing movements common in drawn blood.

Stains with common aniline dyes. Gram-negative. Violet with Giemsa's stain.

Bile salts (10 per cent): Disintegration complete.

Saponin (10 per cent): Immobilized in 30 minutes, then broken up in a few hours. In some a skeletal structure remains.

Cultivation: Can be cultured in ascitic or hydrocoel fluid to which a piece of sterile rabbit kidney is added. Optimum reaction pH 7.2 to 7.4.

Immunology: Serum does not agglutinate *Borrelia duttoni.*

Accidental and experimental transmission by conjunctival sac and skin abrasions.

Disease in experimental animals (small rodents after monkey passage) mild.

Arthropod vector: Louse (*Pediculus humanus*) which exhibits normal transmission from the 16th to the 28th day. Found in the bed-bug (*Cimex lectularius*) and ticks, but not transmitted by them. No evidence of hereditary transmission in the louse.

Habitat: The cause of European relapsing fever. Transmissible to man, monkeys, mice and rats.

3. **Borrelia duttonii** (Novy and Knapp) Bergey et al. (Dutton and Todd, British Med. Jour., *2*, 1905, 1259; *Spirillum duttoni* Novy and Knapp, Jour. Infect. Dis., *3*, March 18, 1906, 296; *Spirochaeta duttoni* Breinl, Lancet, *1*, June 16, 1906, 1690; *Spirochaete duttoni* Lehmann and Neumann, Bakt. Diag., 4 Aufl., *2*, 1907, 623; *Spironema duttoni* Gross, Cent. f. Bakt., I Abt., Orig., *65*, 1912, 94; *Spirochaeta Microspironema duttoni* Duboscq and Lebailly, Compt. rend. Acad. Sci., *154*, 1912, 662; *Spiroschaudinnia duttoni* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 399; *Treponema duttoni* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 497; *Cacospira duttoni* Enderlein, Bakterien-Cyclogenie, 1925, 254; Bergey et al., Manual, 2nd ed., 1925, 434.) Named for Dutton, who discovered this organism.

Morphology: Similar to *Borrelia recurrentis.*

Cultivation: Growth occurs under anaerobic conditions in serum water, hydrocoel or ascitic fluid to which a piece of sterile rabbit kidney is added.

Immunology: This organism is antigenically distinct from other causes of relapsing fever.

Pathogenic for mice and rats. Disease in small rodents and many other experimental animals very severe.

Arthropod vector: This species is transmitted to man through the bite of the tick (*Ornithodoros moubata*) by fecal contamination of the bite. In the tick the organism goes through some granulation or fragmentation phenomenon, the nature of which is not understood. Hereditary transmission to at least the third generation of the tick. Not transmitted by the louse.

Habitat: The cause of Central and South African relapsing fever.

4. **Borrelia kochii** (Novy) Bergey et al. (*Spirochaeta kochi* Novy, Proc. Path. Soc. Philadel., N. S. *10*, 1907, 1; *Spirochaeta rossi* Nuttall, Jour. Roy. Inst. Pub. Health, London, *16*, 1908, 385; *Spiroschaudinnia rossii* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 400; *Spironema kochii* Noguchi, Jour. Exp. Med., *27*, 1918, 584; *Treponema kochi* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 497; *Treponema rossi* Brumpt, *ibid.*; Bergey et al., Manual, 2nd ed., 1925, 434; *Borrelia rossi* Steinhaus, Insect Microbiology, 1946, 452.)

Named for Koch, who first observed spirochetes in East African relapsing fever.

Morphology: Similar to that of *Borrelia recurrentis*.

Cultivation: Same as for *Borrelia recurrentis*.

Immunology: Antigenically distinct from both *Borrelia recurrentis* and *B. duttonii*.

Pathogenic for mice and rats.

Arthropod vector: No record.

Habitat: The cause of African relapsing fever.

5. **Borrelia novyi** (Schellack) Bergey et al. (Spirochaete from relapsing fever, Norris, Pappenheimer and Flournoy, Jour. Inf. Dis., *3*, 1906, 266; *Spirochaeta novyi* Schellack, Arb. kaiserl. Gesundheitsamte, *27*, 1907, 199 and 364; *Spironema novyi* Gross, Archiv f. Protistenk., *24*, 1912, 115; *Spiroschaudinnia novyi* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 400; *Treponema novyi* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 508; *Cacospira novyi* Enderlein, Bakterien-Cyclogenie, 1925, 254; Bergey et al., Manual, 2nd ed., 1925, 434.) Named for Novy, the American bacteriologist.

Morphology: Similar to that of *Borrelia recurrentis*.

Cultivation: Same as for *Borrelia recurrentis*.

Immunology: Antigenically distinct from other relapsing fever organisms.

Pathogenic for monkeys, white rats and white mice.

Arthropod vector: Unknown.

Habitat: Recovered from a patient in Bellevue Hospital, New York. Origin of infection unknown.

6. **Borrelia berbera** (Sergent and Foley) Bergey et al. (*Spirochaeta berbera* Sergent and Foley, Ann. Inst. Past., *24*, 1910, 337; *Spiroschaudinnia berbera* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 402; *Spironema berbera* Noguchi, Jour. Exp. Med., *27*, 1918, 584; *Spirochaeta berbera* Kolle and Hetsch, Exper. Bakt. u. Infekt., 6 Aufl., *1*, 1922, 811; *Treponema berberum* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 496; Bergey et al., Manual, 2nd ed., 1925, 435.) Named for the Berbers, a tribe of Northern Africa.

Morphology: More tenuous than other relapsing fever organisms, 0.2 to 0.3 by 12 to 24 microns.

Cultivation: No record of its cultivation.

Immunology: Antigenically distinct from *Borrelia recurrentis*.

Arthropod vector: Possibly carried by the louse (*Pediculus vestimenti*).

Source: Found in cases of relapsing fever in Algiers, Tunis and Tripoli.

Habitat: Cause of relapsing fever in North Africa. Is virulent for monkeys. Produces non-fatal infections in rats and mice.

7. **Borrelia carteri** (Mackie) Bergey et al. (*Spirochaeta carteri* Mackie, Ann. Trop. Med. and Parasitol., *1*, 1907, 157 and Indian Med. Gazette, *44*, 1908, 370; *Spirillum carteri* Mackie, Lancet, *2*, 1907, 832, according to Ford, Textb. of Bact., 1927, 950; *Spiroschaudinnia carteri* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 401; *Spironema carteri* Noguchi, Jour. Exp. Med., *27*, 1918, 584; *Treponema carteri* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 497; Bergey et al., Manual, 2nd ed., 1925, 435.) Named for Carter, who in 1879 described this organism in the blood of patients with Indian relapsing fever.

Morphology: Similar to *Borrelia berbera*.

Cultivation: Not recorded.

Immunology: Probably a distinct species. A succession of distinct serological types occurs with the relapses in a single infection (Cunningham et al., Far Eastern Association of Tropical Medicine, Tokyo, 1925; Indian Journal of Medical

Research, *22*, 1934–1935, 105 and 595; *ibid.*, *24*, 1937, 571 and 581).

Arthropod vector: Carried by either *Pediculus vestimenti* or *Cimex rotundatus* or by both.

Habitat: The cause of Indian relapsing fever. Transmissible to monkeys, rabbits, rats and mice.

8. **Borrelia theileri** (Laveran) Bergey et al. (*Spirochaeta theileri* Laveran, Compt. rend. Acad. Sci., Paris, *136*, 1903, 939; *Spiroschaudinnia theileri* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 404; *Spironema theileri* Noguchi, Jour. Exp. Med., *27*, 1918, 584; Bergey et al., Manual, 2nd ed., 1925, 435; *Spirillum theileri* and *Spirochaete theileri* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928; *Treponema theileri* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 461.) Named for Theiler, who discovered this organism in 1902 in Transvaal, South Africa.

Morphology: 0.25 to 0.3 micron by 20 to 30 microns with pointed ends.

Cultivation: No record.

Immunology: Is distinct from the species infecting man.

Arthropod vector: Transmitted by the tick (*Rhipicephalus decoloratus*).

Source: Blood of cattle.

Habitat: Blood of cattle and other mammals in South Africa.

9. **Borrelia glossinae** (Novy and Knapp) Bergey et al. (*Spirillum glossinae* Novy and Knapp, Jour. Inf. Dis., *3*, 1906, 385; *Spirochaeta glossinae* Castellani and Chalmers, Man. Trop. Med., 1st ed., 1910, 310; *Spiroschaudinnia glossinae* Castellani and Chalmers, *ibid.*, 3rd ed., 1919, 454; *Spironema glossinae* Bergey et al., Manual, 1st ed., 1923, 425; Bergey et al., Manual, 2nd ed., 1925, 435; *Entomospira glossinae* Enderlein, Bakterien-Cyclogenie, 1925, 254; *Treponema glossinae* Ford, Textb. of Bact., 1927, 988.) Named for the genus of insects, *Glossina*.

Morphology: 0.2 by 8.0 microns, occurring singly, sometimes in pairs. Generally 4 spirals. Shorter, narrower and has more turns than has *Borrelia recurrentis*.

Habitat: Found in the stomach contents of the tse-tse fly (*Glossina palpalis*).

10. **Borrelia buccale** (Steinberg) Brumpt. (*Spirochaeta buccalis* Steinberg, 1862, according to Hoffmann and Prowazek, Cent. f. Bakt., I Abt., Orig., *41*, 1906, 819; *Spirochaete cohnii* Winter, Die Pilze, 1879, 61; (?) *Microspira buccalis* Lewis, The Lancet, 1884, quoted from Schroeter, in Cohn, Kryptog. Flora v. Schlesien, *3*, 1, 1889, 169; *Spirochaete buccalis*, quoted from Schroeter, *ibid.*, 168; *Spirillum cohnii* Trevisan, I generi e le specie delle Batteriacee, 1889, 24; *Spirillum buccale* Macé, Traité Pratique de Bact., 4th ed., 1901, 1062; *Spirochaeta inaequalis* Gerber, Cent. f. Bakt., I Abt., Orig., *56*, 1910, 508; *Spirochaeta undulata* Gerber, *idem*; *Treponema buccale* Dobell, Arch. f. Protistenk., *26*, 1912, 117; *Spironema buccale* Gross, Cent. f. Bakt., I Abt., Orig., *65*, 1912, 84; *Spiroschaudinnia buccalis* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 450; Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 495; *Treponema inaequale* Brumpt, *ibid.*; *Treponema undulatum* Brumpt, *ibid.*, 514.) From Latin *buccalis*, buccal.

Morphology: 0.4 to 0.9 by 7 to 20 microns. The largest of the mouth spirochetes.

Motility: Active, serpentine, rotating and flexuous.

Staining: Stains with aniline dyes and is violet with Giemsa's stain.

Cultivation: Has not been obtained in pure culture and probably does not grow in any medium tried to date.

Habitat: In normal mouths and invades formed lesions of the respiratory mucous membrane.

11. **Borrelia vincentii** (Blanchard) Bergey et al. (*Spirochaeta vincenti* Blanchard, Arch. f. Protistenk., *10*, 1906, 129; *Spirochaeta schaudinni* Prowazek, Arb. kaiserl. Gesundheitsamte, *22*, 1907, 23; *Spirochaete plaut-vincenti* Lehmann and Neumann, Bakt. Diag., 5 Aufl., *2*, 1912, 579; *Spiroschaudinnia vincenti* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 402; *Spiroschaudinnia schaudinni* Castellani and Chalmers, *idem*; *Spironema vincenti* Park and Williams, Pathogenic Microorganisms, 6th ed., 1917, 506; *Treponema vincenti* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 514; *Treponema schaudinni* Brumpt, *idem*; Bergey et al., Manual, 2nd ed., 1925, 435.) Named for Vincent, the French bacteriologist.

Morphology: 0.3 by 8 to 12 microns, 3 to 8 irregular shallow spirals. Stains easily with the common aniline dyes and is Gram-negative.

Motility: Has a rapid progressive and vibratory motion.

Cultivation: Can be cultivated under anaerobic conditions. Cultures may show long forms with only a writhing motion.

Not pathogenic for laboratory animals.

Habitat: Found on normal respiratory mucous membrane and is associated with a fusiform bacillus (*Fusobacterium plauti-vincenti*) in Vincent's angina.

12. **Borrelia refringens** (Schaudinn and Hoffmann) Bergey et al. (*Spirochaeta refringens* Schaudinn and Hoffmann, Arbeiten kaiserl. Gesundheitsamte, *22*, 1905, 528; *Spirochaeta refringens* Hoffmann and Prowazek, Cent. f. Bakt., I Abt., Orig., *41*, 1906, 742; *Spironema refringens* Gross, Arch. f. Protistenk., *24*, 1912, 115; *Spiroschaudinnia refringens* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 459; *Treponema refringens* Castellani and Chalmers, *ibid.*, 461; Bergey et al., Manual, 2nd ed., 1925, 436.) From Latin, refractive.

Morphology: 0.5 to 0.75 by 6 to 20 microns. Spirals are coarse and shallow. Spirals are generally smoothly rounded and regular, tapering towards the end into a fine projection. Stains easily by common dyes. In stained specimens the spirals appear irregular.

Motility: Active serpentine and rotating motion with marked flexion.

Cultivation: Uncertain.

Pathogenicity: None.

Source: Found with *Treponema pallidum* in some cases of syphilis as originally described by Schaudinn.

Habitat: Genital mucous membranes and necrotic lesions of the genitalia of man.

13. **Borrelia hyos** (King and Drake) Bergey et al. (Hog cholera virus, King and Baeslack, Jour. Inf. Dis., *12*, 1913, 39; *Spirochaeta suis* King, Baeslack and Hoffmann, Jour. Inf. Dis., *12*, 1913, 235; not *Spirochaeta suis* Bosanquet, Spirochetes, Saunders, 1911; *Spirochaeta hyos* King and Drake, Jour. Inf. Dis., *16*, 1915, 54; *Spironema hyos* Bergey et al., Manual, 1st ed., 1923, 426; Bergey et al., Manual, 2nd ed., 1925, 436; *Spironema suis* Ford, Textb. of Bact., 1927, 959.) From Greek, hog.

Morphology: 1 micron by 5 to 7 microns. Distinctly shorter and thicker than other members of the genus.

Motility: Active spinning motion, spirals fixed.

Cultivation: Grows under anaerobic conditions in the presence of tissue.

Habitat: Found in the blood, intestinal ulcers and other lesions of hogs suffering from hog cholera.

14. **Borrelia hermsi** (Davis) Steinhaus. (*Spirochaeta hermsi* Davis, Amer. Assoc. Adv. Sci., Pub. No. 18, 1942, 46; Steinhaus, Insect Microbiology, 1946, 453.)

Investigations by Davis (*loc. cit.*) indicate that each species of *Ornithodoros* that is a relapsing fever vector carries a spirochete that is tick-host specific and that this host-specific relationship offers a more accurate approach to the differentiation of relapsing fever spirochetes

than any of the several criteria previously used.

This was shown to be the case for *Borrelia hermsi* and *Borrelia parkeri*. For this reason no attempt is made to describe the morphology and other characters of the relapsing fever spirochetes of North and South America.

Borrelia hermsi is transmitted by *Ornithodoros hermsi*.

A cause of relapsing fever in the Western part of the U. S. A.

15. **Borrelia parkeri** (Davis) Steinhaus. (*Spirochaeta parkeri* Davis, *loc. cit.*; Steinhaus, *loc. cit.*)

Transmitted by *Ornithnodoros parkeri*.

A cause of relapsing fever in the Western part of the U. S. A.

16. **Borrelia turicatae** (Brumpt) Steinhaus. (*Spirochaeta turicatae* Brumpt, Comp. rend. Soc. Biol., Paris, *113*, 1933, 1369; Steinhaus, *loc. cit.*)

Transmitted by *Ornithodoros turicata*.

A cause of relapsing fever in Mexico, Texas and nearby areas.

17. **Borrelia venezuelensis** Brumpt. (*Treponema venezuelensis* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1921, 492; Brumpt, *ibid.*, 495; *Spirochaeta venezuelensis* Pettit, Contributions à l'Étude des Spirochétidés, Vanves, *2*,1928, 295.)

Transmitted by *Ornithodoros rudis* (*O. venezuelensis*).

A cause of South American relapsing fever.

Brumpt (Précis de Parasitologie, 3rd ed., Paris, 1936) regards this species as identical with *Borrelia neotropicalis* (Bates, Dunn and St. John) Steinhaus. (*Treponema neotropicalis* Bates, Dunn and St. John, Amer. Jour. Trop. Med., *1*, 1921, 183; *Spirochaeta neotropicalis* St. John and Bates, Amer. Jour. Trop. Med., *2*, 1922, 251; Steinhaus, *loc. cit.*) Transmitted by *Ornithodoros venezuelensis*. A cause of relapsing fever in **Panama.**

Appendix: Many of the species included in this appendix are so inadequately described that it is not certain that they belong in this group.

Borrelia phagedenis (Noguchi) Bergey et al. (*Spirochaeta phagedenis* Noguchi, Jour. Exp. Med., *16*, 1912, 261; *Spiroschaudinnia phagedenis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 403; *Treponema phagedenis* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 511; *Spironema phagedenis* Bergey et al., Manual, 1st ed., 1923, 426; Bergey et al., Manual, 2nd ed., 1925, 435.) From phagedenous ulcer.

Heliconema pyrphoron Scholer. (Cent. f. Bakt., I Abt., Orig., *138*, 1937, 342.) From human blood. Pathogenic.

Heliconema vincenti Sanarelli. (Ann. Inst. Past., *41*, 1927, 701.) From the intestine of a guinea pig. Shows stages between spirochetes and fusiform bacilli. (See Hindle, Med. Res. Council Syst. of Bact., *8*, 1931, 130.)

Microspironema merlangi Duboscq and Lebailly. (Compt. rend. Acad. Sci. Paris, *154*, 1912, 662.) From the whiting, *Merlangus merlangus*. May be a synonym of *Spirochaeta gadi*.

Spirillum gondii Nicolle. (Nicolle, Compt. rend. Soc. Biol., Paris, *63*, 1907, 213; *Spirochaeta gondi* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1680.) Found in the blood of a rodent, *Ctenodactylus gondi*. Not pathogenic. Associated with a piroplasma. Probably not a spirochete.

Spirillum latapiei Laveran. (Laveran, Bull. Soc. Path. Exot., *1*, 1908, 148; *Spirochaeta latapici* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1683; *Spironema latapici* (sic) Ford, Textb. of Bact., 1927, 964.) From the blood of a shark.

Spirillum pitheci Thiroux and Dufougeré. (Thiroux and Dufourgeré, Compt. rend. Acad. Sci. Paris, *150*, 1910, 132; *Spirochaeta pitheci* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1676; *Spironema pitheci* Ford,

Textb. of Bact., 1927, 961.) From the blood of an African monkey, *Cercopithecus patas*. Pathogenic for monkeys, rats and field mice. Closely related to *Borrelia duttonii*.

Spirochaeta aboriginalis Cleland. (Cleland, Jour. Trop. Med., *12*, 1909, 143; *Spiroschaudinnia aboriginalis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 402; *Treponema aboriginalis* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 496.) Found in cases of granuloma inguinale in West Australia. Probably saprophytic.

Spirochaeta acuminata Castellani. (Castellani, Brit. Med. Jour., *2*, 1905, 1330; *Spirochaeta tenuis acuminata* Castellani, *idem* and/or Arch. f. Schiffs- u. Tropenhyg., *12*, 1908, 311; *Spiroschaudinnia acuminata* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 449; *Treponema acuminatum* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 496.) From ulcerated lesions of yaws.

Spirochaeta acuta Kritchewski and Séguin. (Rev. de Stomatol., *22*, 1920, 613.) From the oral cavity.

Spirochaeta aeglefini Henry. (Jour. Path. and Bact., *18*, 1913, 222.) From haddock.

Spirochaeta aegyptica Gonder. (Gonder, in Prowazek, Handb. d. path. Protoz., *6*, 1914, 671; *Spironema aegyptica* Noguchi, Jour. Exp. Med., *27*, 1918, 584; *Treponema egypticum* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 500; *Borrelia aegypticum* Steinhaus, Insect Microbiology, 1946, 452.) Observed in cases of relapsing fever in Sudan. Probably a synonym of *Borrelia recurrentis*.

Spirochaeta ambigua Séguin and Vinzent. (Séguin and Vinzent, Compt. rend. Soc. Biol., Paris, *121*, 1936, 408; *Treponema ambigua* Prévot, Man. Class. et Determ. d. Bactéries Anaérobies, Paris, 1940, 208.) From the oral cavity and the lungs. Pathogenic. Strict anaerobe.

Spirochaeta amphibiae Yakimoff and Miller. (Bull. Soc. Path. Exot., *18*, 1925, 306.) From the intestines of frogs, *Rana temporaria*.

Spirochaeta argentinensis Kuhn and Steiner. (Kuhn and Steiner, Med. Klin., *13*, 1917, 1007; *Spirochaeta polysclerotica* Arzt and Kerl, according to Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 134; *Treponema* (?) *argentinensis* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 478.) From the livers of guinea pigs and rabbits inoculated with blood from patients having multiple sclerosis. Pathogenic for man, monkeys, dogs, rabbits and guinea pigs. Named for the Latin name of the town of Strasbourg (*Argentoratum*).

Spirochaeta balanitidis Hoffmann and Prowazek. (Hoffmann and Prowazek, Cent. f. Bakt., I Abt., Orig., *41*, 1906, 741; *Spiroschaudinnia balanitidis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 404; *Spironema balanitidis* Park and Williams, Pathogenic Microorganisms, 6th ed., 1917, 505; *Treponema balanitidis* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 496.) From a case of balanitis.

Spirochaeta bovis-caffris Nuttall. (Nuttall, Parasitology, *3*, 1910, 108; *Spironema bovis-caffris* Ford, Textb. of Bact., 1927, 960.) From the blood of a buffalo.

Spirochaeta bronchialis Castellani. (Castellani, Ceylon Medical Reports, 1907; *Spiroschaudinnia bronchialis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 402; *Treponema bronchiale* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 496.) Found in cases of bronchitis in Ceylon. A mixture of several species of mouth spirochaetes is apparently described under this designation.

Spirochaeta bucco-pharyngei Macfie. (Macfie, Ann. Trop. Med. and Parasitol., *10*, 1916, 329; *Treponema bucco-pharyngei* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 497.) From the throat of a native of the Gold Coast. May be identical with *Spirochaeta dentium* or *S. buccalis*.

Spirochaeta bufonis Dobell. (Dobell, Quart. Jour. Microsc. Sci., *52*, 1908, 121; *Spiroschaudinnia bufonis* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 454; *Spironema bufonis* Ford, Textb. of Bact., 1927, 986; *Treponema bufonis* Ford, *ibid.*) From the intestines of a toad, *Bufo vulgaris*.

Spirochaeta caesirae retortiformis Hellmann. (Arch. f. Protistenk., *29*, 1913, 22.) From the urinary sac of a tunicate, *Caesira retortiformis*.

Spirochaeta caesirae septentrionalis Hellmann. (Arch. f. Protistenk., *29*, 1913, 22.) From the urinary sac of a tunicate, *Caesira septentrionalis*.

Spirochaeta canina Bosselut. (Bull. Soc. Path. Exot., *18*, 1925, 702.) From the blood of a dog.

Spirochaeta canis Macfie. (Ann. Trop. Med. and Parasitol., *10*, 1916, 305.) From dog feces.

Spirochaeta cobayae Knowles and Basu (Knowles and Basu, Indian Jour. Med. Res., *22*, 1935, 449; *Treponema cobayae* Topley and Wilson, Princip. Bact. and Immun., 2nd ed., 1936, 725; *Borrelia cobayae* Steinhaus, Insect Microbiology, 1946, 454.) From the blood of guinea pigs. Blood parasite belonging to the relapsing fever group. Pathogenic for guinea pigs, rabbits and white rats.

Spirochaeta comandoni Séguin and Vinzent. (Séguin and Vinzent, Compt. rend. Soc. Biol., Paris, *121*, 1936, 408; *Treponema comandoni* Prévot, Man. Class. et Determ. d. Bactéries Anaérobies, Paris, 1940, 208.) From the oral cavity. Rather common. Non-pathogenic. Strict anaerobe.

Spirochaeta crocidurae Leger. (Leger, Bull. Soc. Path. Exot., *10*, 1917, 280; *Treponema crocidurae* McFarland, Pathogenic Bacteria and Protozoa, 2nd ed., 1933, 136.) From a shrew-mouse, *Crocidura stampflii*, in Senegal. Transmitted by *Ornithodoros erraticus*.

Spirochaeta ctenocephali Patton. (Patton, Ann. Trop. Med. and Parasitol., *6*, 1912, 357; *Treponema ctenocephali* Ford, Textb. of Bact., 1927, 989.) Parasitic in the digestive tract of the larvae of the Indian cat-flea, *Ctenocephalus felis*.

Spirochaeta cubensis Hoffman. (Sanidad y Beneficienca Boletin oficial, Havana, *28*, 1923, 76.) From the feces of *Hyla septentrionalis*.

Spirochaeta culicis Jaffé. (Jaffé, Arch. f. Protistenk., *9*, 1907, 100; *Spironema culicis* Gross, Cent. f. Bakt., I Abt., Orig., *65*, 1912, 87; *Entomospira culicis* Enderlein, Sitzungsber. Ges. Naturf. Freunde, Berlin, 1917, 313; *Spiroschaudinnia culicis* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 454; *Spirillum culicis* Pringault, Compt. rend. Soc. Biol., Paris, *84*, 1921, 209; *Treponema culicis* Ford, Textb. of Bact., 1927, 989.) Found in the intestines and Malpighian tubules of mosquito larvae, *Culex sp.*

Spirochaeta didelphis Vianna, de Figueiredo and Cruz. (Brasil-Medico, *26*, 1912, 912.) From the blood of an opossum, *Didelphis aurita*.

Spirochaeta equi (Novy and Knapp) Castellani and Chalmers. (*Spirillum equi* Novy and Knapp, Jour. Inf. Dis., *3*, 9106, 294; Castellani and Chalmers, Man. Trop. Med., 1st ed., 1910, 309; *Spiroschaudinnia equi* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 404; *Spironema equi* Noguchi, Jour. Exp. Med., *27*, 1918, 584; *Treponema equi* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 461.) From the blood of a horse. May be identical with *Borrelia theileri*.

Spirochaeta equina. (Dodd ?, Jour. Comp. Pathol. and Therap., *19*, 1906, 318; quoted from Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 111.)

Spirochaeta eurygyrata Werner. (Werner, Cent. f. Bakt., I Abt., Orig., *52*, 1909, 241; *Spironema eurgyratum* (sic) Noguchi, Jour. Exp. Med., *27*, 1918, 584; *Spiroschaudinnia eurygyrata* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 451; *Spirillum eurygyrata* Castellani and Chalmers, *ibid.*; *Borrelia eury-*

gyrata Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 495; *Treponema eurygyratum* Brumpt, *ibid.*, 50.) From the intestinal contents of man.

Spirochaeta exanthematotyphi Futaki. (Futaki, Brit. Med. Jour., Oct. 13, 1917; *Treponema exanthematotyphi* Savini, Compt. rend. Soc. Biol., Paris, *88*, 1923, 958.) Found in the kidneys and urine of cases of exanthematous typhus. Non-pathogenic.

Spirochaeta febris Chester. (Afanassiew, Cent. f. Bakt., I Abt., *25*, 1899, 405; Chester, Man. Determ. Bact., 1901, 347.) From a case of recurrent fever.

Spirochaeta gadi Neumann. (Neumann, Ztschr. f. Hyg., *64*, 1909, 79; *Microspironema gadi* Duboscq and Lebailly, Compt. rend. Acad. Sci. Paris, *154*, 1912, 662; *Treponema gadi* Duboscq and Lebailly, Arch. zool. expér. et génér., *10*, 1912, 331; *Spironema gadi* Ford, Textb. of Bact., 1927, 964.) From the blood of a sea fish, *Gadus minutus*.

Spirochaeta gallica Couvy and Dujarric de la Rivière. (Couvy and Dujarric de la Rivière, Compt. rend. Soc. Biol., Paris, *81*, 1918, 22; *Treponema gallicum* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 500.) From the blood of trench fever patients.

Spirochaeta gangraenae carcinomatosae Hoffmann. (Berl. klin. Wochnschr., *42*, 1905, 880.) From malignant tumors.

Spirochaeta gangraenosa nosocomialis Róna. (Róna, Verhandl. d. deutsch. dermat. Gesellsch., *9*, 1907, 471; *Treponema gangraenosa nosocomialis* Noguchi, Jour. Exp. Med., *16*, 1912, 261.) From ulcers of the genital region.

Spirochaeta haemophilus Trosier and Sifferlen. (Ann. Inst. Past., *58*, 1937, 233.) From a child with intestinal trouble and continuous fever.

Spirochaeta hispanica de Buen. (De Buen, Ann. Parasitol., *4*, 1926, 185; *Treponema hispanicum* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 481; *Spirochaeta marocanum* Nicolle and Anderson, Compt. rend. Acad. Sci. Paris, *187*, 1928, 747; *Spirochaeta hispanicum* var. *marocanum* Nicolle, Anderson and Colas-Belcour, Arch. Inst. Past. Tunis, *18*, 1929, 343; *Treponema hispanicum* var. *marocanum* Gay et al., Agents of Disease and Host Resistance, 1935, 1074; *Borrelia hispanicum* Steinhaus, Insect Microbiology, 1946, 453.) The cause of Spanish and Moroccan relapsing fever. Transmitted by *Ornithodoros marocanus*. Not agglutinated by serum of *Borrelia recurrentis*. Pathogenic for man and laboratory animals.

Spirochaeta intestinalis Macfie and Carter. (Macfie and Carter, Ann. Trop. Med. and Parasitol., *11*, 1917, 79; *Treponema intestinale* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 505.) From human feces.

Spirochaeta jonesii Dutton, Todd and Tobey. (Dutton, Todd and Tobey, Jour. Med. Res., *15* (N.S. *10*), 1906, 491; *Spironema jonesii* Ford, Textb. of Bact., 1927, 964.) From the blood of an African mudfish, *Clarias angolensis*.

Spirochaeta lagopodis Fantham. (Fantham, Proc. Zool. Society, London, 1910, 692; *Spironema lagopodis* Noguchi, according to Pettit, *loc. cit.*) From the blood of the grouse, *Lagopus scoticus*.

Spirochaeta leucotermitis Hollande. (Arch. zool. expér. et gén., *61*, 1922, 23.) From an insect, *Leucotermes lucifugus*.

Spirochaeta lovati Fantham. (Proc. Zool. Society, London, 1910.) From the intestinal contents of the grouse, *Lagopus scoticus*.

Spirochaeta lowenthali Besson. (Besson, p. 736, according to Ford, Textb. of Bact., 1927, 1001.) From malignant tumors.

Spirochaeta lutrae Prowazek. (Prowazek, Arb. kaiserl. Gesundheitsamte, *26*, 1907, 31; *Spiroschaudinnia lutrae* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 404; *Spironema lutrae* Ford, Textb. of Bact., 1927, 961.) From the blood of an otter, *Lutra sp.*

Spirochaeta lymphaticus Proescher and White. (Proescher and White, Jour. Amer. Med. Assoc., *49*, 1907, 1988;

Treponema lymphaticum Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 506.) From cases of lymphatic leukemia. Pathogenic for guinea pigs, rats and monkeys.

Spirochaeta macaci Castellani and Chalmers. (Castellani and Chalmers, 1908, see Castellani and Chalmers, Man. Trop. Med., 1st ed., 1910, 310; *Spiroschaudinnia macaci* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 403; *Spironema macaci* Ford, Textb. of Bact., 1927, 960.) From monkeys in Ceylon. Closely related to or possibly identical with *Borrelia carteri*.

Spirochaeta marmotae Carpano. (Ann. d'Igien. sper., *23*, 1913, 215.) From a rodent, *Arctomys marmota*.

Spirochaeta melanogenes canis Lukeš. (Deutsch. Tierärztl. Wochnschr., 1923, 137; see Ann. Inst. Past., *38*, 1924, 523.) From the intestines of a dog. The cause of a dog plague.

Spirochaeta melophagi Porter. (Quart. Jour. Microsc. Sci., London, *55*, 1910, 189.) From the intestine, ovaries, and pupa of *Melophagus ovinus*.

Spirochaeta metritis de Andrade. (Compt. rend. Soc. Biol., Paris, *86*, 1922, 1048.) From a uterine excretion.

Spirochaeta microgyrata gaylordi Calkins. (Calkins, Jour. Inf. Dis., *4*, 1907, 173; *Spirochaeta microgyrata* var. *gaylordi* Calkins, *ibid.*, 171; *Spironema microgyrata* var. *gaylordi* Ford, Textb. of Bact., 1927, 1001.) From breast tumors of mice.

Spirochaeta naganophila Savini. (Compt. rend. Soc. Biol., Paris, *88*, 1923, 956.) From the blood of mice. No description given.

Spirochaeta noelleri Zuelzer. (1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1684.) From the intestine of the larvae of *Simulium noelleri*.

Spirochaeta noguchii Strong. (Strong, United Fruit Co. Med. Dept. 14th Ann. Rept., 1925; *Treponema noguchii* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 483.) From a type of skin ulcer in South America.

Spirochaeta normandi Nicolle, Anderson and Colas-Belcour. (Compt. rend. Acad. Sci. Paris, *185*, 1927, 334.) From *Ornithodoros normandi*, the natural agent of transmission. Pathogenic for white mice.

Spirochaeta normandi var. *carthaginensis*. (Quoted from Hindle, Med. Res. Council Syst. of Bact., *8*, 1931, 169.) From ticks in Tunis.

Spirochaeta nosocomialis Hoffmann and Gonder. (Hoffmann and Gonder, 1914, according to Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 508; *Treponema nosocomiale* Brumpt, *ibid.*) Probably a synonym of *Borrelia vincentii*.

Spirochaeta obtusa Castellani. (Castellani, Brit. Med. Jour., *2*, 1905, 1330; *Spirochaeta tenuis obtusa* Castellani, 1908, according to Ford, Textb. of Bact., 1927, 973; *Spiroschaudinnia obtusa* Castellani, Arch. f. Schiffs- u. Tropenhyg., *12*, 1908, 311 (see Castellani and Chalmers, Man.. Trop. Med., 3rd ed., 1919 449); *Treponema obtusum* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 508; *Treponema tenue obtusum* Brumpt, *ibid.*) From ulcerated lesions of yaws.

Spirochaeta ovis (Novy and Knapp) Bergey et al. (*Spirillum ovis* Novy and Knapp, Jour. Inf. Dis., *3*, 1906, 294; *Spirochaeta ovina* Blanchard, Semaine Médicale, *26*, 1906, 1; *Spiroschaudinnia ovina* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 404; *Spironema ovis* Ford, Textb. of Bact., 1927, 960; *Treponema ovis* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 461; *Treponema ovinum* Noguchi, *ibid.*, 480; Bergey et al., Manual, 5th ed., 1939, 960.) From the blood of sheep. May be identical with *Borrelia theileri*.

Spirochaeta pelamidis Neumann. (Neumann, Ztschr. f. Hyg., *64*, 1909, 80; *Spironema pelamidis* Ford, Textb. of Bact., 1927, 964.) From the blood of a fish, *Pelamys sarda*. Resembles *Spirochaeta gadi*.

Spirochaeta perforans Cavalié and Mandoul. (Compt. rend. Soc. Biol., Paris,

85, 1921, 1068.) From cases of pyorrhea alveolaris. Associated with fusiform bacilli. Probably synonymous with *Borrelia vincentii*.

Spirochaeta periplanetae Laveran and Franchini. (Bull. Soc. Path. Exot., *13*, 1920, 332.) From the digestive tract of the cockroach, *Periplaneta orientalis*.

Spirochaeta persica Dschunkowsky. (Dschunkowsky, Deutsch. med. Wochnschr., *39*, 1913, 419; *Treponema persicum* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 509; *Borrelia persica* Steinhaus, Insect Microbiology, 1946, 452.) From a case of relapsing fever (Mianeh fever) in Persia. Transmitted by *Ornithodoros tholozani* and *O. latiorensis*. Serum not agglutinated by *Borrelia recurrentis*. Disease in man fairly severe and in gerbilles and monkeys very mild.

Spirochaeta pollachii Henry. (*Spirochaeta gadi pollachii* Henry, Jour. Path. and Bact., *14*, 1910, 463; Henry, *ibid.*, *17*, 1912, 160; *Treponema fallax* Duboscq and Lebailly, Arch. Zool. Expér. et Gén., *10*, 1912, 331; *Spirochaeta fallax* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1671; *Spironema pollachii* Ford, Textb. of Bact., 1927, 965.) From the blood of the pollack, *Gadus pollachius*.

Spirochaeta pseudobuccalis Zuelzer. (Cent. f. Bakt., I Abt., Orig., *85*, 1921, *154.)

Spirochaeta pseudorecurrentis Zuelzer. (Cent. f. Bakt., I Abt., Orig., *85*, 1921, *154.)

Spirochaeta pyorrhoeica Kolle. (Med. Klin., *13*, 1917, 59.) Commonly found in pus from pyorrhea alveolaris.

Spirochaeta raillieti Mathis and Leger. (Compt. rend. Soc. Biol., Paris, *70*, 1911, 212.) From the blood of a rabbit. Not pathogenic.

Spirochaeta ranarum Yakimoff and Miller. (Bull. Soc. Path. Exot., *18*, 1925, 306.) From the intestines of frogs, *Rana temporaria*.

Spirochaeta recta Gerber. (Gerber, Cent. f. Bakt., I Abt., Orig., *56*, 1910, 513; *Treponema rectum* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 511.) May be a synonym of *Borrelia vincentii*.

Spirochaeta regaudi Ball and Roquet. (Ball and Roquet, 1911, according to Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928; *Spirella regaudi* Ball and Roquet, 1911, according to Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 517; also see Edkins, Parasitology, *15*, 1923, 296.) From the stomachs of cats and dogs. Possibly belongs among the spirilla (Noguchi); is in the same group as *Cristispirella* and *Heliconema*.

Spirochaeta sinensis Pons. (Compt. rend. Soc. Biol., Paris, *89*, 1923, 1028.) From the blood of a fever patient in China. Pathogenic for rabbits and monkeys.

Spirochaeta sogdianum Nicolle and Anderson. (Nicolle and Anderson, Compt. rend. Acad. Sci. Paris, *187*, 1928, 746; *Borrelia sogdianum* Steinhaus, Insect Microbiology, 1946, 453.) Not pathogenic for guinea pigs or fowls. Probably synonymous with *Borrelia recurrentis*.

Spirochaeta sporogenes psoriasis Rasck. (Individual publications, Christiania, 1920–1921, 4.)

Spirochaeta sporogona rheumatismi Rasck. (Individual publications, Christiania, 1920–1921, 4.) From the blood in cases of acute arthritis.

Spirochaeta staphylina Ghidini and Archetti. (Riv. Biol. Coloniale, *2*, 1939, 131.) From the intestine of a termite, *Reticulitermes lucifugus*, Italy.

Spirochaeta stenogyrata Werner., (Werner, Cent. f. Bakt., I Abt., Orig., *52*, 1909, 241; *Treponema stenogyratum* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 514.) From human feces.

Spirochaeta suilla Dodd. (Jour. Compt. Path. and Therap., *19*, 1906, 216.) From cutaneous lesions of pigs. Pathogenic for pigs.

Spirochaeta temporariae Yakimoff and Miller. (Bull. Soc. Path. Exot., *18*,

1925, 306.) From the intestines of frogs, *Rana temporaria*.

Spirochaeta tenuis Gerber. (Gerber, Cent. f. Bakt., I Abt., Orig., *56*, 1910, 508; *Treponema tenue* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 514.) May be identical with *Spirochaeta dentium* or with *Borrelia vincentii*.

Spirochaeta termitis (Leidy) Dobell. (*Vibrio termitis* Leidy, Jour. Acad. Nat. Sci., Phila., 2nd Ser., *8*, 1881, 441; *Spirochaeta minei* Prowazek, Arch. f. Schiffs- u. Tropenhyg., *14*, 1910, 297; Dobell, Spolia ceylanica, *3*, 1910, 78; *Treponema minei* Dobell, *ibid.; ? Spirochaete grassii* Döflein, Prob. der Protistenk., *2*, 1911, 17; *Spirochaeta grassii* Döflein, Die Natur der Spirochäten, Jena, 1911; *Treponema termitis* Dobell, Arch. f. Protistenk., *26*, 1912, 117; *Entomospira grassii* Enderlein, Sitzungsber. Ges. Naturf. Freunde, Berlin, 1917, 313; *Cristispira termitis* Hollande, Arch. Zool. Expér. et Gén., *61*, 1923, N. and R., 25; *Treponema grassi* Ford, Textb. of Bact., 1927, 988.) From the intestines of *Termes lucifugus* and *Calotermes spp.*

Spirochaeta tropidonoti Dobell. (Dobell, Spolia ceylanica, *7*, 1911, 65; *Spironema tropidonoti* Ford, Textb. of Bact., 1927, 962.) Isolated once from the blood of a snake, *Tropidonotus stolatus*, in Ceylon.

Spirochaeta urethrae Macfie. (Macfie, Ann. Trop. Med. and Parasitol., *10*, 1916, 305; *Spiroschaudinnia urethrae* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 451; *Treponema urethrae* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 514.) From the urine of Gold Coast natives. Causes acute arthritis.

Spirochaeta usbekistanica Pickoul. (Russ. Jour. Trop. Med., *6*, 1928, 612.) From cases of relapsing fever in Bokhara.

Spirochaeta vespertilionis (Novy and Knapp) Castellani and Chalmers. (*Spirillum vespertilionis* Novy and Knapp, Jour. Inf. Dis., *3*, 1906, 294; Castellani and Chalmers, Man. Trop. Med., 1st ed., 1910, 309; *Spiroschaudinnia vespertilionis* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 454; *Spironema vespertilionis* Ford, Textb. of Bact., 1927, 961.) From the blood of a bat, *Vespertilio kuhlii*.

Spirochaeta vincenti var. *bronchialis* Delamare. (Compt. rend. Soc. Biol., Paris, *90*, 1924, 611.)

Spirochaeta zlatogorovi Yakimoff. (Bull. Soc. Path. Exot., *14*, 1921, 532.) From feces.

Spirochaete exanthematica Lewascheff. (Cent. f. Bakt., I Abt., *18*, 1895, 133.) From the blood in cases of typhus fever.

Spirochaete forans Reiter. (Reiter, Deutsch. med. Wochnschr., No. 50, 1916, 10; see Cent. f. Bakt., I Abt., Orig., *79*, 1917, 176; *Treponema forans* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 500; *Spirochaeta forans* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 164.) From the blood in a case of articular rheumatism. Not pathogenic for guinea pigs or mice.

Spirochaete gracilis Veszpremi. (Veszpremi, Cent. f. Bakt., I Abt., Orig., *44*, 1907, 332; not *Spirochaeta gracilis* Levaditi and Stanesco, Compt. rend. Soc. Biol., Paris, *67*, 1909, 188 (*Treponema levaditii* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 501; *Treponema gracile* Brumpt, *idem*); *Treponema gracile* Ford, Textb. of Bact., 1927, 978.) From a gangrenous phlegmon of the mouth. Found in association with fusiform bacilli and therefore may be identical with *Borrelia vincentii* or *Spirochaeta dentium* or *Treponema macrodentium*.

Spirochaete repacis. (Quoted from Lehmann and Neumann, Bakt. Diag., 6 Aufl., *2*, 1920, 809.) From the oral cavity.

Spironema caviae Ford. (Spirochaete (?), Macfie, Ann. Trop. Med. and Parasitol., *8*, 1914, 447; Ford, Textb. of Bact., 1927, 961.) From the blood of a guinea pig at Lagos.

Spironema vesperuginis (Gonder) Ford. (*Spirochaeta vesperuginis* Gonder, Arb. kais. Gesundheitsamte, *27*, 1908, 406; Ford, Textb. of Bact., 1927, 961.) From the blood of a bat, *Vesperugo kuhlii*.

Spiroschaudinnia caviae Sangiorgi.

(Sangiorgi, Pathologica Rivista, *5*, 1913, 428; *Spirochaeta caviae* Hindle, Med. Res. Council Syst. of Bact., *8*, 1931, 174.) From the blood of a guinea pig.

Spiroschaudinnia mitis Castellani and Chalmers. (Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 451; *Treponema mite* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 506.) From urine in mild cases of camp jaundice. Probably not pathogenic.

Treponema lineola (Donné) Brumpt. (*Vibrio lineola* Donné, Recherches Microsc. Nature d. Mucus des Organs Genitourinaires, Paris, 1837; Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 505.) From secretions of the genitalia.

Genus II. Treponema *Schaudinn.*

(*Spironema* Vuillemin, Compt. rend. Acad. Sci. Paris, *140*, 1905, 1567; not *Spironema* Bergey et al., Manual, 1st ed., 1923, 424; Schaudinn, Deutsche med. Wochnschr., *31*, 1905, 1728; *Microspironema* Stiles and Pfender, Amer. Med., *10*, 1905, 936.)

Length 3 to 18 microns. Longer forms due to incomplete division. Protoplasm in acute, regular or irregular spirals. Terminal filament may be present. Some species stain only with Giemsa's stain. Weakly refractive by dark field illumination in living preparations. Cultivated under strictly anaerobic conditions. Pathogenic and parasitic for man and animals. Generally produce local lesions in tissues.

The type species is *Treponema pallidum* (Schaudinn and Hoffmann) Schaudinn.

1. **Treponema pallidum** (Schaudinn and Hoffmann) Schaudinn. (*Spirochaete pallida* Schaudinn and Hoffmann, Arb. kaiserl. Gesundheitsamte, *22*, 1905, 528; Schaudinn, Deutsche med. Wochnschr., *31*, 1905, 1728; *Spironema pallidum* Vuillemin, Compt. rend. Acad. Sci. Paris, *140*, 1905, 1567; *Microspironema pallidum* Stiles and Pfender, Amer. Med., *10*, 1905, 936; *Trypanosoma luis* Krzystalowicz and Siedlecki, 1905, see abst. in Bull. Inst. Past., *4*, 1906, 204; *Spirochaeta pallida* Hoffmann and Prowazek, Cent. f. Bakt., I Abt., Orig., *41*, 1906, 741.) From Latin, pale.

Morphology: Very fine protoplasmic spirals 0.25 to 0.3 by 6 to 14 microns.

Spiral amplitude: 1.0 micron, regular, fixed.

Spiral depth: 0.5 to 1.0 micron.

Terminal spiral filament present.

Weakly refractive in living state by dark field illumination. May appear as a series of bright dots or string of radiant beads with poor dark field illumination.

Staining: Stain with difficulty except with Giemsa's stain by which they appear pink or rose. Appear black with silver impregnation methods.

Motility: Sluggish, drifting motion, stiffly flexible, rarely rotating.

Trypsin digestion: Resistant for many days.

Bile salts (10 per cent): Disintegration complete.

Saponin (10 per cent): Broken up in time.

Cultivation: With difficulty under strict anaerobiosis in ascitic fluid with addition of fresh rabbit kidney.

Habitat: The cause of syphilis in man. Can be transmitted experimentally to anthropoid apes and rabbits.

2. **Treponema pertenue** Castellani. (Castellani, Jour. Trop. Med., *8*, 1905, 253; *Spirochaeta pertenuis* Castellani, Jour. Ceylon Branch Brit. Med. Assoc., June, 1905; *Spirochaeta pallidula* Castellani, Brit. Jour. Med., *2*, Nov., 1905, 1330; *Spirochaete pertenuis* Lehmann and Neumann, Bakt. Diag., 5 Aufl., *2*, 1912, 677; *Spironema pertenue* Gross, Archiv f. Protistenk., *24*, 1912, 115; *Treponema pallidulum* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 508.) From Latin, very fine.

Morphologically indistinguishable from *Treponema pallidum*.

Cultivable under anaerobic conditions in the same medium used for *Treponema pallidum*.

Habitat: The cause of yaws—tropica frambesia. Patients with the disease give a positive Wassermann test. Prbobably transmitted by contact.

3. **Treponema microdentium** Noguchi. (Jour. Exp. Med., *15*, 1912, 81.) From Greek *mikros*, small and Latin, teeth.

The organism is less than 0.25 micron in thickness in the middle and tapers toward each extremity, which is pointed. The length varies with age but may reach 8 microns and show an average of 14 curves. Sometimes a long, thin flagella-like projection is observed at each extremity.

Growth occurs under anaerobic conditions in serum water medium containing fresh tissue. The serum is slightly coagulated and gives off a strong, fetid odor.

Habitat: Normal oral cavity.

4. **Treponema mucosum** Noguchi. (Jour. Exp. Med., *16*, 1912, 194; *Spirochaeta mucosa* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 190.) From Latin, mucous.

Spirals: 0.25 to 0.3 by 8 to 12 microns. The number of curves varies from 6 to 8. Both extremities are sharply pointed and often possess a minute curved projection, 8 to 10 microns long.

Cultivable under anaerobic conditions, forming mucin.

The cultures give off a strong, putrid odor.

Takes the red in Giemsa's stain.

Strict anaerobe.

Source: From pus in a case of pyorrhoea.

Habitat: Found in pyorrhea alveolaris. It possesses pyogenic properties.

5. **Treponema calligyrum** Noguchi. (Noguchi, Jour. Exp. Med., *17*, 1913, 96; *Spirochaeta calligyra* Zuelzer, 1925, in Prowazek, Hand. d. path. Protoz., *3*, 1931, 1673.) From M. L., with beautiful circles.

Morphology: 0.35 to 0.4 by 6 to 14 microns, average 9 to 12 microns. Spirals are regular and deep but more rounded than those of *Treponema pallidum*. The organism is of uniform width until near the extremities which end in sharp points with delicate projections.

Motility: Active, chiefly rotating.

Stains reddish-violet with Giemsa's stain.

Cultivation: Grows under anaerobic conditions.

Not pathogenic for monkeys or rabbits.

Source: From smegma.

Habitat: Lesions and membranes of the pudenda.

6. **Treponema genitalis** Noguchi. (*Treponema minutum* Noguchi, Jour. Exp. Med., *27*, 1918, 671; not *Treponema minutum* Dobell, Arch. f. Protistenk., *26*, 1912, 151; not *Treponema minutum* Castellani, 1916; Noguchi, Laboratory Diagnosis of Syphilis, New York, 1923, 260; *Spirochaeta minutum* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1673; *Spirochaeta genitalis* Séguin and Vinzent, Ann. Inst. Past., *61*, 1938, 255.) From Latin, genital.

Morphology: 0.25 to 0.3 by 3 to 14 microns. Spirals round, regular and shallow. Smaller than *Treponema pallidum* and spirals are closer together.

Motility: Active.

Culture: Grows anaerobically and requires fresh tissue.

Non-pathogenic.

Habitat: Found on male and female genitalia.

7. **Treponema carateum** Brumpt. (Treponema de un caso de pinta, Saenz, Grau Triana and Alfonso, Arch. de Med. Int., Havana, *4*, 1938, 3; Brumpt, Compt. Rend. Soc. Biol., Paris, *130*, 1939, 942; *Treponema herrejoni* León y Blanco, Rev. de Med. Trop. y Parasitol., Habana, *6*, 1940, 5; *Treponema pictor* Pardo-Castello, Rev. de Med. Trop. y Parasitol.

Habana, *6*, 1940, 117; *Treponema pintae* Curbelo, Elementos de Bacteriología Médica, 1941, 34.) From carate, spotted sickness.

Description taken from León y Blanco (*loc. cit.*).

Cylindrical: 0.25 to 0.30 by 7.8 to 36.8 microns, average length 17.8 microns. With sharp-pointed ends.

Spiral amplitude: 1 micron, regular.

Spiral depth: 0.8 to 1.0 micron.

Number of waves, 6 to 27, according to length. Ten to twelve (Brumpt, *loc. cit.*).

Actively motile. At times undulating or creeping movements are shown.

Staining reactions: Readily takes silver impregnations, Giemsa's stain, carbol-fuchsin and gentian violet.

Saponin (10 per cent): Disintegrates in six hours at room temperature. Same result with sodium taurocholate (10 per cent) and with bile.

Distilled water: Produces swelling.

Loses motility on heating for 15 minutes at 50°C or for 3 hours at 41°C.

Wassermann, Kahn and Meinicke reactions positive.

Has not yet been cultivated artificially. Experimental transmission unsuccessful so far.

Source: From the border of cutaneous lesions of persons having pinta (spotted sickness).

Habitat: The cause of pinta (or carate). Common in Mexico and Colombia. Also found in other northern countries of South America, in Central America and the West Indies. Rare in Cuba. Possibly found in other tropical regions of the world.

8. **Treponema cuniculi** Noguchi. (*Spirochaeta paraluis cuniculi* Jakobsthal, Dermatol. Wchnschr., *71*, 1920, 569; Noguchi, Jour. Amer. Med. Assoc., *77*, 1921, 2052; also see Noguchi, Jour. Exp. Med., *35*, 1922, 395; *Treponema pallidum* var. *cuniculi* Klarenbeek, Cent. f. Bakt., I Abt., Orig., *87*, 1921, 203; *Spirochaeta cuniculi* Seraditi, Marie and Isaien, Compt. rend. Soc. Biol., Paris, *85*, 1921, 51; *Spirochaeta pallida* var. *cuniculi* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1765; *Spirochaeta paraluis* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 91; *Spirochaeta paraluis-cuniculi* Hindle, Med. Res. Council Syst. of Bact., *8*, 1931, 187.) From Latin, rabbit.

Description from Noguchi (*loc. cit.*).

Closely resembles *Treponema pallidum*, but longer.

Width 0.25 micron; length 10 to 16 microns; long specimens up to 30 microns frequent.

Spirals 8 to 12 in number, regular, deep.

Spiral amplitude 1 to 1.2 microns.

Spiral depth 0.6 to 1.0 micron.

Delicate terminal filament at one, sometimes both, ends.

Often forms entangled masses of long threads; occurs sometimes in a stellate arrangement.

Staining properties same as for *Treponema pallidum*. Both readily stained by ordinary basic analine dyes when fixed in a buffered formaldehyde solution.

Wassermann reaction negative.

Pathogenesis: Disease transmissible to healthy rabbits, producing papular lesions in the genitoperineal region. Not pathogenic for monkeys, mice or guinea pigs.

Source: From lesions in the genitoperineal region of five rabbits.

Habitat: The cause of rabbit spirochetosis.

Appendix: Many of the species in this appendix are so inadequately described that it is not certain that they belong in this group.

Microspironema legeri Duboscq and Lebailly. (Duboscq and Lebailly, Compt. rend. Acad. Sci. Paris, *154*, 1912, 662; *Treponema legeri* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1683.) From a fish, *Box boops*.

Spirochaeta microgyrata Loewenthal. (Loewenthal, Berl. klin. Wochnschr., *43*, 1906, 283; *Spironema microgyrata* Nogu-

chi, Jour. Exp. Med., *27*, 1918, 584; *Spiroschaudinnia microgyrata* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 454; *Treponema microgyratum* Brumpt, Nouveau Traité de Médecine, *4*, 1922, 506.) From cancerous ulcers of man, dogs, and mice. Regarded by Hoffmann and Prowazek (Cent. f. Bakt., I Abt., Orig., *41*, 1906, 819) as identical with *Spirochaeta dentium*.

Spirochaeta parotitidis Lehmann. (In Lehmann and Neumann, Bakt. Diag., 7 Aufl., *2*, 1927, 580.) Pathogenic, producing a disease similar to mumps in experimental animals (cats) and causing parotitis and orchitis in apes.

Spirochaeta penortha Beveridge. (Austral. Jour. Expt. Biol. and Med. Sci., *14*, 1936, 307.) This organism is also called *Treponema podovis* according to Shahan, in Keeping Livestock Healthy, U. S. D. A. Yearbook of Agriculture, Part 6, 1942, 830.) Present as an accessory factor in foot-rot of sheep. Also see *Actinomyces nodosus*.

Spirochaeta phlebotomi Pringault. (Compt. rend. Soc. Biol., Paris, *84*, 1921, 209.) From the sand fly, *Phlebotomus perniciosus*.

Spirochaeta pseudopallida Mulzer. (Mulzer, Berl. klin. Wchnschr., *42*, 1905, 1144; *Spiroschaudinnia pseudopallida* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 449; *Treponema pseudopallidum* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 511.) Found in ulcerating carcinomata.

Spirochaeta skoliodonta Hoffmann. (Hoffmann, Cent. f. Bakt., I Abt., Orig., *86*, 1920, 137; *Spirochaeta acuta* Kritchevsky and Séguin, 1920, according to Séguin and Vinzent, Ann. Inst. Past., *67*, 1941, 62; *Treponema skoliodontum* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 481.) From the peritoneal exudate of a guinea pig. One of the smallest known spirochetes. From the oral cavity.

Spirochaeta subtilis Castellani. (Castellani, 1907; *Spiroschaudinnia subtilis* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 450; *Treponema subtile* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 514; *Spironema subtilis* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928.) From the oral mucosa and from intestinal contents. May be a synonym of *Spirochaeta dentium*.

Spirochaeta urethralis Castellani. (Castellani, 1915; *Treponema urethrale* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 1944.) From a purulent urethral discharge.

Spirochaeta vaccinae Bonhoff. (Bonhoff, Berl. klin. Wochnschr., *42*, 1905, 1142; *Treponema vaccinae* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 515.) From vaccinia.

Spirochaeta vaginalis Macfie. (Macfie, Ann. Trop. Med. and Parasitol., *10*, 1916, 315; *Treponema vaginalis* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 514.) From a case of vaginitis in a Gold Coast native.

Spirochaete hartmanni Gonder. (Gonder, Cent. f. Bakt., I Abt., Orig., *47*, 1908, 491; *Spironema hartmanni* Gross, Cent. f. Bakt., I Abt., Orig., *65*, 1912, 88; *Spirochaeta hartmanni* Noguchi, Jour. Exp. Med., *34*, 1921, 297; *Treponema hartmanni* Ford, Textb. of Bact., 1927, 990.) From the digestive tract of molluscs, *Pinna spp.*

Spirochaete polyspira Wolff. (Wolff, Cent. f. Bakt., II Abt., *18*, 1907, 448; *Treponema polyspirum* Wolff, *ibid.*; *Spirochaeta polyspira* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 14.) From rotten potatoes.

Treponema carpanoi Yakimoff and Rastjapin. (Arch. f. Protistenk., *71*, 1930, 543.) From stomatitis of horses.

Treponema cotti Duboscq and Lebailly. (Duboscq and Lebailly, Arch. Zool. Expér. et Gén., *10*, 1912, 331; *Microspironema cotti* Duboscq and Lebailly, Compt. rend. Acad. Sci., Paris, *154*, 1912, 662.) From the marine bullhead, *Cottus bubalis*.

Treponema dentium (Miller) Dobell. (Spirochaete im Zahnschleim, Cohn, Beitr. z. Biol. d. Pflanzen, *1*, Heft 2, 1872,

180; *Spirochaete denticola* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 390; *Spirochaete dentium* Miller, Microorganisms of the Human Mouth, Philadelphia, 1890, 80; *Spirillum dentium* Sternberg, Manual of Bact., 1893, 694; *Spirochaeta dentium* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., *1*, 1a, 1895, 35; *Spirochaeta denticola* Arndt, according to Hoffmann and Prowazek, Cent. f. Bakt., I Abt., Orig., *41*, 1906, 819; Dobell, Arch. f. Protistenk., *26*, 1912, 117; *Spironema dentium* Gross, Cent. f. Bakt., I Abt., Orig., *65*, 1912, 88; *Spirochaeta dentinum* McFarland, Pathogenic Bacteria and Protozoa, 7th ed., 1912, 546; *Treponema microdentium* Noguchi, Jour. Exp. Med., *15*, 1912, 81; *Spirochaeta orthodonta* Hoffmann, Deutsch. med. Wochnschr., *46*, 1920, 257; *Spirochaeta microdentium* Heim, Lehr. d. Bakt., 6 and 7 Aufl., 1922, 477; *Treponema denticola* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 497; *Treponema orthodontum* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 481; *Treponema dentium-stenogyratum* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 240.) The smallest of the mouth spirochaetes. Non-pathogenic. This term probably includes several morphologically similar species which have not as yet been sufficiently characterized.

Treponema drosophilae Chatton. (Compt. rend. Soc. Biol., *73*, 1912, 212.) From *Drosophila confusa*. Six to thirty microns in length, tapers at both ends, four spirals, movement helicodal.

Treponema gallicolum Lebailly. (Compt. rend. Soc. Biol., Paris, *75*, 1913, 389.) From the caecum of the hen, *Gallus sp.*

Treponema hilli Duboscq and Grassé. (Compt. rend. Soc. Biol., Paris, *94*, 1926, 34; Arch. Zool. Expér. et Gén., *66*, 1927, 484.) From the surface of the body of a flagellate, *Devescovina hilli*, and in the intestine of a termite, *Glyptotermes iridipennis*. A very small organism.

Treponema intermedium Dobell. (Mittelformen, Lühe, Handb. d. Tropenkrankh., *3*, 1906; see Hoffmann and Prowazek, Cent. f. Bakt., I Abt., Orig., *41*, 1906, 819; Dobell, Arch. f. Protistenk., *26*, 1912, 117; *Treponema macrodentium* Noguchi, Jour. Exp. Med., *15*, 1912, 81; *Spirochaeta media oris* Hoffmann, Deutsch. med. Wochnschr., *46*, 1920, 257; *Treponema medium* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 505; *Spirochaeta intermedia* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 146; *Spirochaeta macrodentium* Pettit, *ibid.*, 182; *Spirochaeta media* and *Spironema media* Pettit, *ibid.*, 240.) The middle-sized spirochete of the mouth.

Treponema lari Lebailly. (Compt. rend. Soc. Biol., Paris, *75*, 1913, 389.) Found in the caecum of birds, also in the guinea-pig. Named for one of the birds, *Larus ridibundus*.

Treponema minutum Dobell. (*Treponema sp.* Dobell, Quart. Jour. Microsc. Sci., *52*, 1908, 121; Dobell, Arch. f. Protistenk., *26*, 1912, 151; not *Treponema minutum* Castellani, 1916; not *Treponema minutum* Noguchi, Jour. Exp. Med., *27*, 1918, 671; *Spirochaeta minutum* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1682.) From the large intestines of toads, *Bufo vulgaris*.

Treponema parvum Dobell. (Dobell, Arch. f. Protistenk., *26*, 1912, 117; *Spirochaeta parvum* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1685.) From the intestine of the cockroach, *Stylopyga* (*Blatta*, *Periplaneta*) *orientalis*. Very small organism.

Treponema pavonis Duboscq and Lebailly. (Arch. Zool. Expér. et Gén., *10*, 1912, 331.) From the intestine of the blenny, *Blennius pavo*.

Treponema perexile Duboscq and Lebailly. (Duboscq and Lebailly, Arch. Zool. Expér. et Gén., *10*, 1912, 331; *Spirochaeta perexilis* Hindle, Med. Res. Council Syst. of Bact., *8*, 1931, 180.) From the blood of a marine fish, *Lepadogaster bimaculatus*.

Treponema podovis Ludovic and Blaizot. (Compt. rend. Acad. Sci. Paris, *187*,

1928, 911.) Pathogenic. Cause of a disease in sheep.

Treponema querquedulae Lebailly. (Compt. rend. Soc. Biol., Paris, *75*, 1913, 389.) From caeca of birds. Named for the teal, *Querquedula querquedula*.

Treponema rhinopharyngeum Brumpt. (*Treponema minutum* Castellani, 1916; *Spiroschaudinnia minuta* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 1881; Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 514.) From man in cases of rhinopharyngitis. Probably a synonym of *Spirochaeta gracilis*.

Treponema rigidum Zinsser and Hopkins. (Jour. Bact., *1*, 1916, 489.) From the tissues in five different strains of rabbit syphilis. Probably a synonym of *Treponema cuniculi*.

Treponema spermiformis Duboscq and Grassé. (Arch. Zool. Expér et Gén., *66*, 1927, 483.) From the rectum of a termite, *Glyptotermes iridipennis*.

Treponema squatarolae Lebailly. (Compt. rend. Soc. Biol., Paris, *75*, 1913, 389.) From the caecum of a bird, *Squatarola squatarola*.

Treponema stylopygae Dobell. (Dobell, Arch. f. Protistenk., *26*, 1912, 117; *Spirochaeta stylopygae* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1685.) From the intestines of the cockroach, *Stylopyga orientalis*.

Treponema tricalle Cohn. (Cohn, 1872, quoted from Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 414.)

Treponema triglae Duboscq and Lebailly. (Arch. Zool. Expér et Gén., *10*, 1912, 331.) From the rectum of a fish, *Trigla lucerna*.

Treponema tropiduri Neiva, Marques da Cunha and Travassus. (Mem. do Inst. Oswaldo Cruz, *6*, 1914, 180.) From the blood of a South American lizard, *Tropidurus torquatus*.

The following species are listed in the index of Castellani and Chalmers, Manual of Tropical Medicine, 2nd ed., 1913, 1718–1719, but are not mentioned in the text (pp. 136–141): *Treponema bovidae*, *T. camelidae*, *T. canidae*, *T. felidae*, *T. hippopotami*, *T. reptilia*, *T. rhinoceri*, *T. selachii*, *T. suidae*, *T. ungulata* and *T. ursidae*.

Genus III. Leptospira *Noguchi.*

(Jour. Exp. Med., *25*, 1917, 753.)

Finely coiled organisms 6 to 20 microns in length. Spirals 0.3 micron in depth and 0.4 to 0.5 micron in amplitude. In liquid medium one or both ends are bent into a semicircular hook each involving $\frac{1}{10}$ to $\frac{1}{8}$ of the organism. Spinning movements in liquid and vermiform in semisolid agar, forward or backward. Seen in living preparations only with dark field. Stain with difficulty except with Giemsa's stain and silver impregnation. Require oxygen for growth.

The type species is *Leptospira icterohaemorrhagiae* (Inada and Ido) Noguchi.

1. **Leptospira icterohaemorrhagiae** (Inada and Ido) Noguchi. (*Spirochaeta icterohaemorrhagiae* Inada and Ido, Tokyo Ijishinski, 1915; Inada, Ido, Hoki, Kaneko and Ito, Jour. Exp. Med., *23*, 1916, 377; *Spirochaeta icterogenes* Uhlenhuth and Fromme, Med. Klin., *11*, 1915, 1202; *Spirochaeta nodosa* Huebner and Reiter, Deutsch. med. Wochnschr., *41*, 1915, 1275; Noguchi, Jour. Exp. Med., *25*, 1917, 755; *Spiroschaudinnia icterohaemorrhagiae* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 447; *Treponema icterogenes* Gonder and Gross, Arch. f. Protistenk., *39*, 1919, 62; *Spirochaete ictero-haemorrhagica* (sic) Lehmann and Neumann, Bakt. Diag., 6 Aufl., *2*, 1920, 810; *Treponema ictero-hemorragiae* (sic) Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 501; *Treponema nodosum*

Brumpt, *ibid.*, 508; *Leptospira icterogenes* Ford, Textb. of Bact., 1927, 994; *Leptospira nodosa* Ford, *ibid.*, 993.) From Greek *icterus*, jaundice and *hemorrhagiae*, bleeding.

Morphology: 0.25 to 0.3 by 6 to 9 microns and occasionally 20 to 25 microns.

Spiral amplitude: 0.4 to 0.5 micron, regular, rigid.

Spiral depth: 0.3 micron, regular.

Waves: One or more gentle waves throughout entire length. When in liquid media, one or both ends may be semicircularly hooked, while in semisolid media the organism appears serpentine, waved or bent. Very active flexibility.

Terminal filament and flagella absent.

Body stains reddish by Giemsa's stain.

Bile salts (10 per cent): Easily dissolved.

Saponin (10 per cent): Completely resistant.

Cultured easily in medium containing 10 per cent rabbit serum, 0.2 per cent agar, slight amount of hemoglobin in salt or Ringer's solution. Does not grow in surface colonies.

Temperature range: 25° to 37°C. Remains alive longer at 25°C.

Pathogenic for guinea pigs and deermice.

Habitat: The cause of infectious jaundice in man (Weil's disease). Found in the kidneys, urine and blood of wild rats. No insect vector known. Found free-living in water and slime (in mines).

2. **Leptospira hebdomadis** (Ido et al.) Noguchi. (*Spirochaeta nanukayami* Ido, Hoki, Ito and Wani, Nippon Gakkai Zasshi, *5*, 1917, No. 5; *Spirochaeta hebdomadis* Ido, Ito and Wani, Jour. Exp. Med., *28*, 1918, 435; *Spiroschaudinnia hebdomadis* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 448; Noguchi, Jour. Exp. Med., *30*, 1919, 17; *Treponema hebdomadis* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 501.) From Latin, seven days.

Morphologically indistinguishable from *Leptospira icteroheamorrhagiae* but can be distinguished serologically.

In man causes less jaundice than *Leptospira icterohaemorrhagiae* and is never fatal.

Identical with Type B, *Leptospira autumnalis*.

Slightly pathogenic for young guinea pigs.

Is carried by the field vole (*Microtus montibelli*).

Habitat: Cause of seven-day fever or gikiyami in Japan.

3. **Leptospira biflexa** (Wolbach and Binger) Noguchi. (*Spirochaeta biflexa* Wolbach and Binger, Jour. Med. Res., *30*, 1914, 23; Noguchi, Jour. Exp. Med., *27*, 1918, 585; *Spirochaeta pseudo-icterogenes* (*aquatilis*) Uhlenhuth and Zuelzer, Cent. f. Bakt., I Abt., Orig., *85*, 1921,* 141; *Spirochaeta pseudoicterogenes* Uhlenhuth and Zuelzer, Klin. Wochnschr., *1*, 1922, 2124; *Spirochaeta pseudo-icterohemorrhagiae* Vinzent, Compt. rend. Soc. Biol., Paris, *95*, 1926, 1472; *Leptospira pseudoicterogenes* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 461.) From Latin, doubly bent.

Size: 0.2 to 0.25 by 5 to 7 microns with tapering ends. Spiral amplitude 0.2 to 0.25 micron. Will pass through an L5 candle filter.

Waves: 22 to 30 in number.

Stains: Best results with Giemsa's stain.

Culture: Can grow in distilled water plus 0.1 per cent potassium nitrate. Rabbit serum in distilled water is best medium.

Optimum temperature 20°C.

Antigenically distinct from *Leptospira icterohaemorrhagiae*.

Not pathogenic.

Source: From tap water, ponds and pools in Berlin.

Habitat: Fresh water.

4. **Leptospira canicola** Okell et al. (Okell, Dalling and Pugh, Vet. Jour., *81*, 1925, 3.) From Latin, dog-dweller.

Morphologically indistinguishable from *Leptospira icterohaemorrhagiae*.

Cultivation: Same as *Leptospira icterohaemorrhagiae*.

Immunology: Some cross-reaction with *Leptospira icterohaemorrhagiae*, but specific in higher dilutions of immune serum.

Source: From blood of dogs.

Habitat: A natural parasite of dogs. Causes a chronic disease of old dogs characterized by uremia, not jaundice. Fatal in 80 per cent of those infected. No intermediate host known. Probably transmitted by direct contact; possibly by healthy carriers.

Appendix: The species listed below are inadequately described and may be identical with those described in full.

Leptospira aqueductum (sic) Ford. (*Spirochaeta pseudoicterogenes aquaeductuum* Uhlenhuth and Zuelzer, Cent. f. Bakt., I Abt., Orig., *85*, 1921, *150; Ford, Textb. of Bact., 1927, 998.) From fresh water of aqueducts. Probably a synonym of *Leptospira biflexa*.

Leptospira asthenoalgiae Carbo-Noboa. (Bull. Inst. Past., *22*, 1924, 898.) From blood, urine and organs of persons having dengue.

Leptospira autumnalis Topley and Wilson. (Akiyami Type A, Koshina, Shiwozawa and Kitayama, Japan. Med. Wld., *4*, 1924, 268; see also Jour. Exp. Med., *42*, 1925, 873; Topley and Wilson, Princip. Bact. and Immun., 1st ed., *2*, 1931, 1202; *Spirochaeta autumnalis A*, quoted from Hindle, Med. Res. Council Syst. of Bact., *8*, 1931, 312; *Spirochaeta autumnalis* Hindle, *ibid.*) The cause of akiyami or harvest sickness in Japan. May be identical with *Leptospira icterohaemorrhagiae*.

Leptospira bataviae. (1925, quoted from Gispen and Schüffner, Cent. f. Bakt., I Abt., Orig., *144*, 1939, 427.) From a case of fever in the Dutch East Indies. Probably a synonym of *Leptospira hebdomadis*.

Leptospira biliohemoglobinuriae (Blanchard and Lefrou) Noguchi. (*Spirochaeta bilio-hemoglobinuriae* Blanchard and Lefrou, Compt. rend. Acad. Sci., Paris, *175*, 1922, 602; Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 490.) From cases of blackwater fever.

Leptospira bonariensis Savino and Rennella. (Rev. Inst. Bact. "Dr. Carlos G. Malbram", *12*, 1944, 182.) From gray rats.

Leptospira bovis Noguchi. (New York State Med. Jour., *22*, 1922, 426.) From the gastric mucosa of the ox.

Leptospira couvyi Gomes de Faria. (Compt. rend. Soc. Biol., Paris, *90*, 1924, 55; *Spirochaeta couvyi* Hindle, Med. Res. Council Syst. of Bact., *8*, 1931, 317.) From the blood of persons having dengue.

Leptospira dentale Perrín. (Rev. Mex. de Biol., *2*, 1922, 171.) Found in the pus of bucco-maxillary gangrene.

Leptospira grippo-typhosa Topley and Wilson. (Topley and Wilson, Princip. Bact. and Immun., 2nd ed., 1936, 728; *Spirochaeta dmitrovi* Rimpau, Schlossberger and Kathe, Cent. f. Bakt., I Abt., Orig., *141*, 1938, 320.) The cause of swamp fever in Europe. Probably synonymous with *Leptospira hebdomadis*. Also see Baschenin, Cent. f. Bakt., I Abt., Orig., *113*, 1929, 438 and 450; Dinger and Verschaffelt, Ann. Inst. Past., *45*, 1930, 396.

Leptospira haemoglobinuriae Schüffner. (Geneesk. Tijdschr. Ned. Indië, *58*, 1918, 352; *Spirochaeta haemoglobinuriae* Hindle, Med. Res. Council Syst. of Bact., *8*, 1931, 314.) From the blood of a Javanese patient suffering from an attack of blackwater fever.

Leptospira icterohemoglobinuriae Schüffner. (Schüffner, Geneesk. Tijdschr. v. Ned. Indië, *58*, 1918, 352, according to Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928; *Spirochaeta icterohemoglobinuriae* Schüffner, Mededeel. Burgerl. Geneesk. Dienst in Nederl. Indië, *58*, 1918, 7 (according to Blanchard and Lefrou, Compt. rend. Acad. Sci., Paris, *175*, 1922, 602); *Treponema icterohemoglobinuriae* Brumpt,

Nouveau Traité de Médecine, Paris, *4*, 1922, 501.) From the blood in a case of blackwater fever.

Leptospira interrogans (Stimson) Noguchi. (*Spirochaeta interrogans* Stimson, U. S. Public Health Rept., Part I, *22*, 1907, 541; *Leptospira icteroides* Noguchi, Jour. Exp. Med., *29*, 1919, 581; *Treponema interrogans* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 505; *Treponema icteroides* Brumpt, *ibid.*; *Spirochaeta icteroides* Lehmann and Neumann, Bakt. Diag., 7 Aufl., *2*, 1927, 576; Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 454.) Noguchi (1928) regards this species as identical with *Leptospira icterohaemorrhagiae.*

Leptospira pettiti (Fiessinger) Hindle. (*Spirochaete pettiti* Fiessinger, Ann. de Méd., *5*, 1918, 156; *Treponema pettiti* Brumpt, Nouveau Traité de Médecine, Paris, *4*, 1922, 510; Hindle, Med. Res. Council Syst. of Bact., *8*, 1931, 316; *Spirochaeta pettiti* Hindle, *idem*; not *Spirochaeta pettiti* Row, Jour. Trop. Med. and Hyg., 1922, 364.) From urine. Morphologically indistinguishable from *Leptospira icterohaemorrhagiae.*

Leptospira pyrogenes Vervoort. (Vervoort, Geneesk. Tijdschr. v. Ned. Indië, *63*, 1923, 800; *Spirochaeta febrilis* Vervoort, Rep. Far East. Assoc. Trop. Med., London, 1923, 683; *Spirochaeta pyrogenes* Hindle, Med. Res. Council Syst. of Bact., *8*, 1931, 314.) From the blood of persons suffering from dengue-like fevers in Sumatra. Pathogenic.

Leptospira saxkoebing Petersen. (Acta Path. et Microbiol. Scand., *21*, 1944, 165.) A new serological type.

Leptospira salina Ford. (*Spirochaeta pseudoicterogenes salina* Uhlenhuth and Zuelzer, Cent. f. Bakt., I Abt., Orig., *85*, 1921, *150; Ford, Textb. of Bact., 1927, 998.) From salt water.

Leptospira trimerodonta (Hoffmann) Noguchi. (*Spirochaeta trimerodonta* Hoffmann, Deutsch. med. Wochnschr., *46*, 1920, 257; *Leptospira dentium* Hoffmann, *ibid.*, 625; *Leptospira buccalis* Fontana, according to Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 232; Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 461.) From the oral cavity. May be synonymous with *Leptospira icterohaemorrhagiae.*

Spirochaeta anthropopitheci Wilbert and Delorme. (Ann. Inst. Past., *41*, 1927, 1147.) Pathogenic for chimpanzees in French Guinea. Probably identical with *Leptospira icterohaemorrhagiae.*

Spirochaeta elusa Wolbach and Binger. (Wolbach and Binger, Jour. Med. Res., *30*, 1914, 9; *Treponema elusum* Bergey et al., Manual, 1st ed., 1923, 428.) From pond water. Not pathogenic. For a description of this species, see Bergey et al., Manual, 5th ed., 1939, 957.

Spirochaeta ictero-uraemia canis Klarenbeek. (Tijdschr. Diergeneesk., *55*, 1928, 227.) From the kidneys of dogs. Pathogenic for guinea pigs. May be synonymous with *Leptospira icterohaemorrhagiae* or *L. canicola.*

Spirochaeta pseudohebdomadis Zuelzer. (1925, in Prowazek, Handb. d. path. Protoz., *3*, 1931, 1671.) Probably identical with *Leptospira hebdomadis.*

Spirochaeta trimeres Hoffmann. (Deutsch. med. Wochnschr., *46*, 1920, 257.) From the oral cavity. May be synonymous with *Leptospira trimerodonta.*

SUPPLEMENT NO. 1.

ORDER RICKETTSIALES

April, 1947.

ORDER RICKETTSIALES GIESZCZYKIEWICZ.

(Bull. Intern. Acad. Polon. Sci., Classe Math. Nat., B(1), 1939, 9–30.)

Small, rod-shaped, coccoid, spherical and irregularly-shaped microorganisms which stain lightly with aniline dyes. Gram-negative. Usually not filterable. Cultivated outside the body, if at all, only in living tissue, embryonated eggs or rarely in media containing body fluids. Parasitic organisms intimately associated with tissue cells and erythrocytes, chiefly in vertebrates and often in arthropods which act as vectors. The intracellular parasites of *Protozoa* may also belong here. May cause diseases in man or animals, or both.

Key to the families of order **Rickettsiales.**

I. Intracellular parasites, or parasites intimately associated with tissue cells. Do not occur in erythrocytes. Frequently cause diseases of vertebrates transmitted by arthropod vectors.
  Family I. *Rickettsiaceae*, p. 1083.

II. Facultative intracellular or extracellular parasites found characteristically in or on the erythrocytes of vertebrates. May be transmitted by arthropod vectors.
  Family II. *Bartonellaceae*, p. 1100.

III. Intracellular parasites found in vertebrate tissues and not transmitted by arthropod vectors.
  Family III. *Chlamydozoaceae*, p. 1114.

*FAMILY I. RICKETTSIACEAE PINKERTON.

(Pinkerton, Parasitology, *28*, 1936, 186; *Rickettsiales* Buchanan and Buchanan, Bacteriology, 4th ed., New York, 1938, 49.)

Small, often pleomorphic, rod-shaped, ovoid, coccoid and coccus-shaped bacterium-like organisms, intimately associated with arthropod tissues, usually in an intracellular position. Stain lightly with aniline dyes. Gram-negative. Have not been cultivated to date in cell-free media. May be parasitic to man and other animals causing diseases (typhus and related ills) that are transmitted by arthropod vectors (lice, fleas, ticks, mites and probably other ectoparasites).

Key to the genera of family **Rickettsiaceae.**†

I. Cells rod-shaped, ellipsoidal and coccoid.
  A. Non-filterable.
    Genus I. *Rickettsia*, p. 1084.
  B. Filterable.
    Genus II. *Coxiella*, p. 1092.

II. Cells spherical, occasionally elongated.
    Genus III. *Cowdria*, p. 1094.

---

* Prepared by Dr. Ida A. Bengtson (retired), National Institute of Health, Bethesda, Maryland, November, 1946. Through the courtesy of Dr. Edward A. Steinhaus much use was made of material from his book, Insect Microbiology, Ithaca, 1946, 763 pp. before it was generally available.

† Includes only those rickettsiae which have been rather completely studied. For additional rickettsiae, see appendix.

Genus I. **Rickettsia** *da Rocha-Lima.*

(Berl. klin. Wchnschr., *53*, 1916, 567–569.) Named for Howard Taylor Ricketts who lost his life studying typhus fever.

Small, often pleomorphic, rod-shaped to coccoid organisms occurring intracytoplasmically in lice, fleas, ticks and mites, or sometimes intranuclearly. Stain lightly with aniline dyes. Gram-negative. Non-filterable. Have not been cultivated in cell-free media. Parasites of man and animals which are the etiological agents of epidemic typhus, murine or endemic typhus, Rocky Mountain spotted fever, tsutsugamushi disease, rickettsialpox and other diseases.

For reasons that are discussed elsewhere (Bengtson, Jour. Bact., *53*, 1947, 325) the genus *Dermocentroxenus* has been united with the genus *Rickettsia*.

The type species is *Rickettsia prowazekii* da Rocha-Lima.*

Key to the species of genus **Rickettsia.**

I. Louse-borne.
   1. *Rickettsia prowazekii.*

II. Flea-borne.
   2. *Rickettsia typhi.*

III. Tick-borne.
   3. *Rickettsia rickettsii.*
   4. *Rickettsia conorii.*

IV. Mite-borne.
   5. *Rickettsia tsutsugamushi.*
   6. *Rickettsia akari.*

1. **Rickettsia prowazekii** da Rocha-Lima. (da Rocha-Lima, Berl. klin. Wchnschr., *53*, 1916, 567; *Rickettsia exanthematotyphi* Kodama, Kitasato Arch. Exper. Med., *9*, 1932, 360; *Rickettsia prowazeki* var. *prowazeki* Pinkerton, Parasitology, *28*, 1936, 186; *Rickettsia prowazeki* sub-species *prowazeki* Philip, Amer. Jour. Hyg., *37*, 1943, 307.) Named for S. von Prowazek who lost his life studying typhus fever.

Minute coccoid, ellipsoidal and ovoid forms to short rods, sometimes long rods and occasionally filamentous forms, often in pairs and occasionally in chains. In infected lice the minute coccoid and paired coccoid forms predominate over the short and long rods and the filamentous forms which are up to 40 microns in length. Single elements 0.25 by 0.4 to 0.3 by 0.45 micron. Pairs range from 0.25 by 0.7 to 0.3 by 1.1 microns. In yolk sacs the organisms vary in size from minute coccoid forms in heavily infected tissue to rod forms resembling small bacteria in lightly infected tissue. Within the same smear of infected mammalian cells and in chick embryo tissue the organisms are quite uniform in size and morphology. Occur intracytoplasmically in vascular endothelial cells and in serosal cells. Non-motile.

* The Editors of the MANUAL follow Recommendation XL of the International Botanical Code (see p. 59) in regard to the endings used for specific names. This calls for the use of the *ii* ending for epithets taken from the name of a man ending in a consonant (except names ending in *er*). Some students of the *Rickettsiaceae* follow the International Rules of Zoological Nomenclature which use *ii* only in case the name used was employed and declined in Latin. Zoologists use the single *i* for modern patronymics based on all other names of men.

The organisms are colored purplish with the Giemsa stain, the two individuals of a pair being connected by a zone of faintly blue stained material. They are colored blue with Castañeda stain (Jour. Inf. Dis., *47*, 1930, 416) and bright red against a blue background with Machiavello stain (Rev. Chilena de Hig. y Med. Prev., *1*, 1937, 101). Gram-negative.

Cultivation: In plasma tissue cultures of mammalian cells, in the louse intestine, in modified Maitland media with and without agar, on chorio-allantoic membrane and yolk sac of chick embryo, the latter being currently the medium of choice.

Optimum temperature 32°C in plasma tissue culture, 35°C in chick embryo cells.

Immunology: Immunity prolonged but may not be complete in man. Indistinguishable from endemic (murine) typhus in cross immunity tests in guinea pigs, but distinguishable from Rocky Mountain spotted fever and other rickettsial diseases in such tests. Neutralizing antibodies are found in the serum of recovered guinea pigs and convalescent humans up to 2 to 3 weeks after defervescence. Killed vaccines produced from infected lice and from infected yolk sacs afford a high degree of protection against the disease. Hyperimmune antisera for therapeutic use have been produced in rabbits by injection with infected yolk sac suspensions and in horses and donkeys with infected mouse lung suspensions.

Serology: Strains from various parts of the world are closely related as determined by complement fixation; are distinguishable from other rickettsiae by agglutination, complement fixation and precipitin tests; have a common antigenic factor (alkali stable polysaccharide) with *Proteus* OX19; and have a soluble antigen in yolk culture.

Lethal effect: Heavily infected yolk sac cultures injected intravenously or intraperitoneally are fatal to white mice in a few hours.

Resistance to chemical and physical agents: Readily inactivated by heat and chemical agents. A temperature of 50°C kills the organism in 15 to 30 minutes, and 0.5 per cent phenol and 0.1 per cent formalin kill the organism.

Pathogenicity: Pathogenic for man, apes, monkeys, guinea pigs, cotton rats, gerbilles, the louse (*Pediculus humanus*). Inapparent infections occur in white mice, white rats and rabbits. A characteristic febrile reaction with no mortality and without testicular swelling occurs in the guinea pig. Passage in guinea pigs is accomplished by transfer of blood or brain from infected animals. Causes a febrile disease with exanthema and high mortality in man.

Source: Seen in the blood of typhus patients and in smears of epithelial cells of the intestinal tract of lice fed on typhus patients.

Habitat: The body louse (*Pediculus humanus* var. *corporis*), head louse (*Pediculus humanus* var. *capitis*) and *Pedicinus longiceps*. The etiological agent of epidemic typhus (European typhus, classical typhus, typhus exanthematicus).

2. ***Rickettsia typhi** (Wolbach and Todd) Philip. (*Dermacentroxenus*

---

* Some may regard the binomial *Rickettsia typhi* as invalid because of its previous use by do Amaral and Monteiro for the organism causing eastern Rocky Mountain spotted fever. However, because the binomial *Dermacentroxenus typhi* Wolbach and Todd clearly has priority and because the binomial proposed by do Amaral and Monteiro has never come into general use, *Rickettsia typhi* Philip has been accepted for use in the MANUAL. If Philip's binomial had been rejected, then it would have been necessary to accept *Rickettsia manchuriae* Kodama et al. as this appears to have priority over the more generally used *Rickettsia mooseri* Monteiro.—Editors.

typhi Wolbach and Todd (not Tood), Ann. Inst. Past., *34*, 1920, 158; minute intracellular bodies, Mooser, Jour. Inf. Dis., *43*, 1928, 261; *Rickettsia manchuriae* Kodama, Takahashi and Kono, Saikingaku-Zasshi (Jap.), No. 426, 427, Aug. and Sept., 1931; see Kodama, Kono and Takahashi bibliography, Kitasato Arch. Exper. Med., *9*, 1932, 95; *Rickettsia mooseri* Monteiro, Mem. Inst. Butantan, *6*, 1931, 97 (pub. July, 1932), see do Amaral and Monteiro, bibliography, *ibid.*, *7*, 1932, 367; *Rickettsia exanthematofebri* Kodama, Kitasato Arch. Exp. Med., *9*, 1932, 360; *Rickettsia muricola* Monteiro and Fonseca, Brazil Med., *46*, 1932, 1032; *Rickettsia murina* and *Rickettsia fletcheri* Megaw, Trans. Roy. Soc. Trop. Med. Hyg., *29*, 1935, 105; *Rickettsia prowazeki* var. *mooseri* Pinkerton, Parasitology, *28*, 1936, 185; *Rickettsia prowazeki* sub-species *typhi* Philip, Amer. Jour. Hyg., *37*, 1943, 304; *Rickettsia typhi* Philip, *idem*; not *Rickettsia typhi* do Amaral and Monteiro, Rev. Sud. Amér. de Méd. et Chirug., *4*, 1933, 806.) From M. L. *typhus*, typhus.

Resembles *Rickettsia prowazekii* in morphological and staining properties. Non-motile. Gram-negative.

Cultivation: May be cultivated in plasma tissue culture of mammalian cells, in modified Maitland media with and without agar, in fleas, in the peritoneal cavity of X-rayed rats, in the lungs of white mice and in white rats following intranasal inoculation, in the lungs of rabbits following intratracheal inoculation, in the chorio-allantoic membrane and the yolk sac of the chick embryo.

Optimum temperature 35°C in chick embryo cells.

Immunology: Prolonged immunity in man and animals following infection. Complete cross immunity between epidemic and endemic typhus in guinea pigs recovered from infections with *Rickettsia prowazekii* and *Rickettsia typhi*. No cross immunity between endemic typhus and Rocky Mountain spotted fever, Q fever or tsutsugamushi disease in guinea pigs.

Serology: Distinguishable from the rickettsiae of spotted fever, Q fever and tsutsugamushi disease by complement fixation, agglutination and precipitin tests, less readily from *R. prowazekii* by these tests. Has common antigenic factor with *Proteus* OX19, and soluble antigen in yolk-sac cultures.

Lethal effect: Heavily infected yolk sac cultures injected intravenously or intraperitoneally fatal to white mice in a few hours.

Pathogenicity: Pathogenic for man, apes, monkeys, rabbits, guinea pigs, white rats, eastern cotton rat, white mice, gerbilles. Other susceptible animals include the woodchuck, house mouse, meadow mouse, white-footed mouse, old-field mouse, cotton mouse, golden mouse, wild rat (*Rattus norvegicus*), wood rat, rice rat, flying squirrel, gray squirrel, fox squirrel, gophers, cotton-tail rabbit, swamp rabbit, chipmunk, skunk, opossum and cat. A characteristic febrile reaction occurs in the guinea pig with testicular swelling without ulceration, after intraperitoneal inoculation. Passage in guinea pigs is accomplished by transfer of testicular washings or blood from infected animals. Cause of a febrile disease with exanthema in man, with low mortality.

Source: Seen by Wolbach and Todd (*loc. cit.*) in the endothelial cells of the capillaries, arterioles and veins in sections of skin from cases of Mexican typhus (tabardillo). Also described by Mooser (*loc. cit.*) in sections and smears of the proliferated tunica vaginalis of guinea pigs reacting to the virus of Mexican typhus.

Habitat: Infected rat fleas (*Xenopsylla cheopis*, *Xenopsylla astia*), infected chicken fleas (*Echidnophaga gallinacea*) found on wild rats, and the rat louse (*Polyplax spinulosus*). Wild rats and field mice act as the reservoir of infection. The etiological agent of en-

demic (murine) typhus which is transmitted to man by the rat flea.

3. **Rickettsia rickettsii** (Wolbach) Brumpt. (*Dermacentroxenus rickettsi* Wolbach, Jour. Med. Res., *41*, 1919–20, 87; *Rickettsia rickettsi* Brumpt, Précis de Parasitologie, 3rd ed., 1922, 757; *Rickettsia brasiliensis* Monteiro, Mem. Inst. Butantan, *6*, 1931, 3; **Rickettsia typhi* do Amaral and Monteiro, Rev. Sud. Amér. de Méd. et Chirurg., *4*, 1933, 806; *Dermacentroxenus rickettsi* var. *brasiliensis* Pinkerton, Parasitology, *28*, 1936, 186.) *Rickettsia dermacentroxenus*, a corruption of *Dermacentroxenus rickettsi*, though widely used, has no genuine taxonomic standing. Named for Howard Taylor Ricketts, who first transmitted the disease from human cases to monkeys and guinea pigs with the production of characteristic symptoms and lesions and fatal effect.

Minute paired organisms surrounded by a narrow clear zone or halo and often lanceolate, resembling in appearance a minute pair of pneumococci. Approximately 0.2 to 0.3 micron by 1 micron. Non-motile.

In smears of mammalian tissues there occur in addition to the lanceolate forms, slender rod-shaped forms stained blue with the Giemsa stain, sometimes exhibiting polar granules, stained purplish or reddish. There are also minute pale blue-staining rounded forms. In the tick there are three forms: (1) Pale blue bacillary forms curved and club-shaped, (2) smaller bluish rods with deeply staining chromatoid granules and (3) more deeply staining, purplish, lanceolate forms. A very minute form may appear in tightly packed masses in the nuclei of the cells. Occurs in the cytoplasm and nucleus in all types of tissue in the tick and in the vascular endothelium, in the serosal cells of the peritoneal cavity, in the smooth muscle cells of arteriolar walls and in the macrophages of mammals.

In yolk sac cultures and in the Maitland media cultures, bacillary forms often occur in pairs. In single smears from infected yolk sacs, the rickettsiae are rather uniform in size and morphology and are definitely larger than *Rickettsia prowazekii* and *Rickettsia typhi*. They also grow more sparsely. Stain blue with the Castañeda stain and bright red against a blue background of tissue with the Machiavello stain.

Cultivation: May be cultivated in plasma tissue culture of mammalian cells, in Maitland media with and without agar, on the chorio-allantoic membrane and in the yolk sac of the chick embryo, and in ticks.

Optimum temperature 32°C in plasma tissue culture, 35°C in chick embryo cells.

Immunology: Prolonged immunity in man and animals after recovery from infection. Killed vaccines produced from infected ticks and from infected yolk sacs afford considerable protection against the disease. Therapeutic antisera have been produced by the injection of rabbits with tick virus and with infected yolk sac. No cross immunity between spotted fever in guinea pigs recovered from infections with *Rickettsia rickettsii* and typhus in guinea pigs recovered from infections with *Rickettsia prowazekii* and *Rickettsia typhi*. Cross immunity between spotted fever in guinea pigs recovered from infections with *Rickettsia rickettsii* and boutonneuse fever in guinea pigs recovered from infections with *Rickettsia conorii*, but spotted fever vaccine does not protect against boutonneuse fever of the Mediterranean area or against infections with the South African strains of *Rickettsia conorii*.

---

* Erroneously applied by do Amaral and Monteiro to the so-called eastern type of Rocky Mountain spotted fever.—Editors.

Serology: Distinguishable from *Rickettsia prowazekii* and *Rickettsia typhi* by complement fixation and agglutination with specific antigens. Distinguishable from *Rickettsia conorii* by complement fixation, though some degree of cross fixation indicates antigenic relationship. Has common antigenic factor with *Proteus* OX19 but not distinguishable from *Rickettsia prowazekii* and *Rickettsia typhi* by Weil-Felix test.

Resistance to chemical and physical agents: Readily inactivated by heat and chemical agents. Destroyed by a temperature of 50°C in 10 minutes, and by 0.5 per cent phenol and 0.1 per cent formalin. Destroyed by desiccation in about 10 hours.

Pathogenicity: Pathogenic for man, monkeys and guinea pigs. Rabbits and white rats are moderately susceptible. Animals susceptible in varying degrees include species of ground squirrels, tree squirrels, chipmunks, cotton-tail rabbits, jack rabbits, snowshoe rabbits, marmots, wood rats, weasels, meadow mice and deer mice. In Brazil the opossum, rabbit, dog and cavy have been found naturally infected and the Brazilian plains dog, capybara, coati and certain bats are also susceptible. Sheep are mildly susceptible.

A febrile reaction occurs in guinea pigs with typical scrotal lesions, involving petechial hemorrhages in the skin, which may become necrotic. Virulent strains kill 80 to 90 per cent of the animals, milder strains kill 20 to 25 per cent. Passage in guinea pigs is accomplished by transfer of blood from infected animals. A febrile reaction accompanied by exanthema occurs in man. Mortality is high in some localities, low in others.

Source: Seen by Ricketts (Jour. Amer. Med. Assoc., *52*, 1909, 379) in the blood of guinea pigs and monkeys experimentally infected with Rocky Mountain spotted fever and in the salivary glands, alimentary sac and ovaries of infected female *Dermacentor* ticks and in their ova.

Habitat: Infected wood tick (*Dermacentor andersoni*) and the dog tick (*Dermacentor variabilis*), also the rabbit tick (*Haemaphysalis leporis-palustris*), *Amblyomma brasiliensis*, *Amblyomma cajennense*, *Amblyomma striatum*, *Amblyomma americanum* and *Ixodes dentatus*. A number of ticks belonging to the genera *Amblyomma*, *Dermacentor*, *Rhipicephalus*, *Ornithodoros* and *Haemaphysalis* have been experimentally infected. The virus is transmissible through the ova of female ticks. The etiological agent of Rocky Mountain spotted fever, Saõ Paulo exanthematic typhus of Brazil, Tobia fever of Colombia and spotted fever of Minas Geraes which are all transmitted to man by the bite of infected ticks.

4. **Rickettsia conorii** Brumpt. (Brumpt, Compt. rend. Soc. Biol., Paris, *110*, 1932, 1199; *Rickettsia megawi* var. *pijperi* do Amaral and Monteiro, Mem. Inst. Butantan, 7, 1932, 361; *Rickettsia blanci* Caminopétros, 1er Cong. Internat. Hyg. Mediterr., Rapports et Compt. rend., *2*, 1932, 202; *Dermacentroxenus rickettsi* var. *pijperi* Mason and Alexander, Onderst. Jour. Vet. Sci. and An. Indust., *13*, 1939, 74; *Dermacentroxenus rickettsi* var. *conori* Mason and Alexander, *ibid.*; *Dermocentroxenus conori* Steinhaus, Insect Microbiology, 1946, 339.) Named for A. Conor who with A. Bruch published in 1910 the first clinical description of boutonneuse fever.

Resembles *Rickettsia rickettsii*. In the tick, diplococcoid and diplobacillary forms predominate, though when the rickettsiae occur in compact masses they are smaller and more coccoid. In tissue cultures the organisms are lanceolate, diplococcoid, and diplobacillary, occurring in the nuclei as well as in the cytoplasm of the cells. Size 0.3 to 0.4 by 1 to 1.75 microns. Non-motile.

Stain purplish with the Giemsa stain,

blue with the Castañeda stain and bright red with a blue background with the Machiavello stain. Gram-negative.

Cultivation: May be cultivated in plasma tissue culture of mammalian cells, in modified Maitland media, and in the yolk sacs of chick embryos.

Immunology: The disease is related immunologically to Rocky Mountain spotted fever with which it cross immunizes, but the spotted fever vaccine does not protect against the Mediterranean and South African strains of boutonneuse fever.

Serology: Distinguishable from *Rickettsia rickettsii* by complement fixation. Has a common antigenic factor with *Proteus* OX19 and OX2.

Pathogenicity: Pathogenic for man and guinea pigs. It is also pathogenic in varying degrees for dogs, horses, spermophiles, monkeys, rabbits, gerbilles and white mice.

Boutonneuse fever is a much less virulent infection for the guinea pig than Rocky Mountain spotted fever. A temperature reaction occurs, accompanied by scrotal swelling but there is no sloughing. There is practically no mortality. Passage in guinea pigs is accomplished by transfer of blood from an infected animal.

In man, localized primary sores (taches noires) and an inflammatory reaction in the regional lymph nodes occur at the site of the tick bite. A febrile reaction with exanthema occurs and mortality is low.

Source: Seen by Caminopétros (Compt. rend. Soc. Biol., Paris, *110*, 1932, 344) in smears from the tunica vaginalis of guinea pigs inoculated with infected dog ticks (*Rhipicephalus sanguineus*).

Habitat: The brown dog tick (*Rhipicephalus sanguineus*) and also the ticks, *Amblyomma hebraeum*, *Haemaphysalis leachi*, *Rhipicephalus appendiculatus* and *Boöphilus decoloratus*. Transmissible through the ova of adult female ticks. The probable animal reservoir is the dog. The etiological agent of boutonneuse fever in man, also known as eruptive, Mediterranean or Marseilles fever and probably Kenya typhus and South African tick bite fever, though the identity of the latter with boutonneuse fever has been questioned.

5. °**Rickettsia tsutsugamushi** (Hayashi) Ogata. (*Theileria tsutsugamushi*

° Some may question the use of this binomial on the ground that Hayashi thought that this species was possibly or probably protozoan in nature when he proposed the name *Theileria tsutsugamushi* (*loc. cit.*) in 1920. However he questions whether *Theileria* is the correct generic name in this paperand accepts the viewpoint that this organism is a rickettsia in a paper published in 1924 entitled, On Rickettsia, Trans. Jap. Path. Soc., *14*, 1924, 198-201. He does not use the binomial *Rickettsia tsutsugamushi* in this paper as indicated by some of his friends in latter papers (Ogata, *loc. cit.*, Kawamura, *loc. cit.*) and apparently first uses it himself in a paper entitled, On Tsutsugamushi Disease, Jap. Path. Soc., *22*, 1932, 686.

Hayashi was not the first to recognize the probable rickettsial nature of the organism of the tsutsugamushi disease (see Blake et al., Amer. Jour. Hyg., *41*, 1945, 257-262) and some even question whether any of the bodies that he found in human lymphocytes from lymph nodes, in mononuclear endothelial phagocytes of the spleen and lymph nodes, and in tissues taken from the region of the mite bite in patients suffering from tsutsugamushi fever were the same as organisms described as *Rickettsia orientalis* by Nagayo et al. (*loc. cit.*).

This position is not supported, however, by Nagayo and his associates who admit that their organisms are identical with some of the organisms described by Hayashi. Mitamura (Trans. Jap. Path. Soc., *21*, 1931, 463) sums this up as follows: "Wir stellen

Hayashi, Jour. Parasit., 7, 1920, 63; **Rickettsia orientalis* Nagayo, Tamiya, Mitamura and Sato, Jikken Igaku Zasshi, *14*, May 20, 1930, 8 pp.; †*Rickettsia tsutsugamushi* Ogata, Cent. f. Bakt., I Abt., *122*, 1931, 249; *Rickettsia akamushi* Kawamura and Imagawa, *ibid.*, *122*, 1931, 258; *Rickettsia orientalis* var. *schüffneri* do Amaral and Monteiro, Mem. Inst. Butantan, 7, 1932, 360; *Rickettsia megawi* do Amaral and Monteiro, *idem; Rickettsia megawi* var. *fletcheri* do Amaral and Monteiro, *ibid.*, 361; *Rickettsia tsutsugamushi-orientalis* Kawamura, Nisshin Igaku, *23*, 1934, 000; *Rickettsia pseudotyphi* Vervoort, see Donatien and Lestoquard, Acta Conv. Tertii Trop. atque malariae morbis, pars I, 1938, 564; *Rickettsia sumatranus* (sic) Kouwenaar and Wolff, Proc. 6th Pacific Sci. Cong. (1939), *5*, 1942, 636; *Dermacentroxenus orientalis* Moshkovsky, Uspekhi Souremennoi Biologii (Russian) (Advances in modern biology), *19*, 1945, 13.) From two Japanese ideographs transliterated *tsutsuga*, something small and dangerous, and *mushi*, a creature now known to be a mite. If the *i* ending is accepted as forming a Latin genitive the modern meaning of the species name *tsutsugamushi*, would be 'of a dangerous mite'.

Small pleomorphic bacterium-like microorganisms, usually thicker than *Rickettsia prowazekii*, *Rickettsia typhi*, *Rickettsia rickettsii* and *Coxiella burnetii* and less sharply defined. Ellipsoidal or rod-shaped, often appearing as a diplococcus or as a short bacillus with bipolar staining resembling the plague bacillus. Diffusely distributed in the cytoplasm of the cell. Size 0.3 to 0.5 by 0.8 to 2

---

nicht in Abrede dass Herr Hayashi bei einem kleinen Teil der von ihn beschriebenen Körperchen unsere *Rickettsia orientalis* vor sich gehabt hat". Hayashi vigorously defends his own observations in the same discussion and the following year after making comparative studies of strains of *Rickettsia orientalis* and his own *Rickettsia tsutsugamushi* reaches the following conclusion (*loc. cit.*) "*Rickettsia tsutsugamushi* and *Rickettsia orientalis* refer to one and the same species of microorganisms and there seems to be no way in which one can be recognized as differing from the other." Under these conditions the only valid name appears to be *Rickettsia tsutsugamushi*.—Editors.

* These authors publish practically the same preliminary paper in three other places as follows: Compt. rend. Soc. Biol., Paris, *104*, June 14, 1930, 637–641; Jap. Jour. Exper. Med., *8*, Aug. 20, 1930, 309–318 and Trans. Jap. Path. Soc., *20*, 1930, 556–566. The complete report on this work did not appear until the following year: Jap. Jour. Exper. Med., *9*, March 20, 1931, 87–150.—Editors.

† This binomial apparently first appears in the literature in a review article by Kawamura (Handbuch der path. Microorganismen, Kolle and Wassermann, 3 Aufl., *8*, 1930, 1398) where it is used incidentally and is attributed to Hayashi, 1923. The fact that Hayashi did not use *Rickettsia tsutsugamushi* before 1931 is confirmed by Mitamura (Trans. Jap. Path. Soc., *21*, 1931, 463) who states in a footnote: Kawamura und Ogata geben an, dass Hayashi 1923 für den Erreger den Namen *Rickettsia tsutsugamushi* vorgeschlagen hat. Eine solche Angabe Hayashi, is nicht nur uns, sondern auch dem Autor, wie er uns persönlich erzählt, unbekannt." Ogata apparently first used *Rickettsia tsutsugamushi* in the title of a paper that he presented in 1930 to the 8th Cong. Far East Assoc. Trop. Med. which, however, appeared in the Transactions of the Congress, *2*, June, 1932, 167–171. Meanwhile, the same paper with an added discussion of the nomenclature appeared in the Cent. f. Bakt., I Abt., Orig., *122*, Oct. 1, 1931, 249–253 and it is this paper that is usually regarded as establishing the use of *Rickettsia tsutsugamushi* for this species.—Editors.

microns. Non-motile. Colored purplish with the Giemsa stain, and red against a blue background with the Machiavello stain. Stains well with azur III and methylene blue. Gram-negative.

Cultivation: In plasma tissue culture of mammalian cells; on the chorio-allantoic membrane and in the yolk sac of the chick embryo; in rabbit testes and in the endothelial cells overlying Descemet's membrane of the rabbit eye.

Immunology: Immunity conferred by infection appears less complete than in typhus and Rocky Mountain spotted fever. Strains from several different areas have been found to cross immunize in guinea pigs, but the true relationship of the disease occurring in different localities remains to be determined. Reciprocal cross-immunity between mite strains and human strains has been demonstrated in rabbits, hamsters and mice.

Serology: Antigens from different strains vary in sensitivity when tested by complement fixation with immune sera. There are probably a number of different types on the basis of complement fixation with immune sera. Has a common antigenic factor with *Proteus* OX-K.

Resistance to chemical and physical agents: Readily inactivated by heat and chemical agents. Destroyed by a temperature of 50°C for 10 minutes, and by 0.1 per cent formalin and 0.5 per cent phenol.

Pathogenicity: Pathogenic for man, monkeys, gibbons, guinea pigs, hamsters, rats, voles, mice, gerbilles, rabbits (by intraocular injection) and chick embryo. There is wide variation in the virulence of different strains for laboratory animals, infection being established with great difficulty with some, while others may cause a high mortality.

A febrile reaction occurs in guinea pigs. Passage in guinea pigs and mice is accomplished by inoculation of infected spleen or blood from an infected animal, passage in rabbits by intraocular inoculation of blood, lymph node or organ emulsions of infected animals. Ascites, enlarged spleen often with a fibrinous deposit are characteristic.

In man an eschar with adenopathy develops at the site of the mite bite. In scrub typhus the eschar is not present. A febrile reaction with exanthema occurs and mortality is variable.

In rabbits infection of Descemet's membrane follows intraocular injection of infected material.

Source: Seen by Hayashi in smears and sections of the lesion (eschar) at the site of the mite bite and in smears and sections of the adjacent lymph nodes from cases of the disease; also seen by Nagayo et al. (*loc. cit.*) in the endothelial cells overlying Descemet's membrane in rabbits inoculated intraocularly with infectious material.

Habitat: The mites (*Trombicula akamushi*, *Trombicula deliensis* syn. *T. walchi*, *Trombicula fletcheri* and probably several others). Infective through the ova of the adult female. Only the larvae feed on rodents or man. Reservoir hosts are probably certain wild rodents, including house and field rats, mice and voles and probably some birds. The etiological agent of tsutsugamushi disease and scrub typhus (for numerous other designations of the disease see Farner and Katsampes, U. S. Naval Med. Bull., *43*, 1944, 800).

NOTE: *Rickettsia nipponica* Sellards. (Sellards, Amer. Jour. Trop. Med., *3*, 1923, 545; *Rickettsoides nipponica* da Rocha-Lima, in Kolle and Wasserman, Handb. d. path. Mikroorganismen, 3 Aufl., *8*, 1930, 1350.) This problematical organism was thought by its author to be the cause of tsutsugamushi disease. Because it was cultivatible by the methods used by Sellards, it is not now regarded as identical with *Rickettsia tsutsugamushi* Ogata. *Rickettsoides nipponica* is the type species (monotypy) of the

genus *Rickettsoides* da Rocha-Lima (*loc. cit.*).

6. **Rickettsia akari** Huebner, Jellison and Pomerantz. (Pub. Health Rept., *61*, 1946, 1682.) From *Acarus*, a genus of mites.

Minute diplobacilli, occurring intracellularly and extracellularly, and bipolarly stained rods. Resemble typical rickettsiae morphologically. Non-motile.

Stain well by Machiavello's method, the organisms appearing bright red against a blue background. Stain poorly with methylene blue. Gram-negative. Occur intracytoplasmically and have been seen intranuclearly in yolk sac cells.

Cultivation: In the yolk sac of the chick embryo. No growth on artificial culture media.

Immunology: Guinea pigs recovered from rickettsialpox are immune to infection with strains isolated from infected mites.

Serology: Antigens prepared from infected yolk sacs are highly specific except for cross reactions with Rocky Mountain spotted fever antigens. Sera from convalescent patients fixed complement with the homologous antigen and usually with Rocky Mountain spotted fever antigens though at a lower titer. Does not have a common antigenic factor with *Proteus* strains except that low titers were obtained in a few recovered cases in agglutination tests with *Proteus* OX19.

Pathogenicity: Pathogenic for man with focal initial erythematous lesion and adenopathy, followed by fever and appearance of macular rash. No mortality. Experimental infections have been produced in white mice and guinea pigs by the inoculation of infected blood (irregularly), and of infected liver and spleen suspensions, infected brain, infected lymph nodes, tunica washings of infected animals and by infected yolk sacs. Symptoms in mice include inactivity, accelerated respiration, ruffled fur, with occasional deaths; in guinea pigs, fever and marked scrotal reactions. Infected embryos are killed in 4 to 7 days. It has not been found pathogenic for monkeys, distinguishing it from *Rickettsia conorii*. It is also probably more pathogenic for white mice than *Rickettsia conorii*.

Source: Blood of a human case of rickettsialpox in New York City.

Habitat: Blood of human cases and an ectoparasite of rodents, the mite (*Allodermanyssus sanguineus* Hirst). The etiological agent of human rickettsialpox.

Genus II. **Coxiella** *Philip.*

(Subgenus *Coxiella* Philip, Amer. Jour. Hyg., *37*, 1943, 306; *Coxiella* Philip, Pub. Health Repts., U. S. P. H. S., *63*, Jan. 9, 1948, 58; not Bengtson, *gen. nov.* as stated in first printing Manual, 6th ed., Jan. 26, 1948, 1092.)

Small, pleomorphic, rod-shaped and coccoid organisms, occurring intracellularly in the cytoplasm and extracellularly in infected ticks. Stain lightly with aniline dyes. Gram-negative. They are filterable. Have not been cultivated in cell-free media. Parasites of man and animals which include the etiological agent of Q fever.

The type species is *Coxiella burnetii* (Derrick) Bengtson.

1. **Coxiella burnetii** (Derrick) Bengtson *comb. nov.* (*Rickettsia burneti* Derrick, Med. Jour. Australia, *1*, 1939, 14; *Rickettsia diaporica* Cox, Pub. Health Rep., *54*, 1939, 1826; *Rickettsia burneti* var. *americana*, Anon., Brit. Med. Jour., *2*, 1941, 588; *Rickettsia* (*Coxiella*) *burneti* Philip, Amer. Jour. Hyg., *37*, 1943, 306.) Named for F. M. Burnet who discovered the organism in Australia.

Small bacterium-like, pleomorphic organisms varying in size from coccoid forms to well marked rods. Occur as cytoplasmic micro-colonies with diffuse or compact distribution of the organisms through the cytoplasm. Also seen extracellularly, where they appear as small lanceolate rods, diplobacilli and occasionally segmented filamentous forms. Chains of 3 to 6 elements often seen. Quite uniform in size and morphology in infected yolk sacs and in mouse spleen with exceedingly minute forms in heavily infected material. Small lanceolate rods, 0.25 by 0.4 to 0.5 micron, bipolar forms 0.25 by 1.0 micron, diplobacilli 0.25 by 1.5 microns. Non-motile.

With Giemsa's stain they appear reddish-purple, with Machiavello's stain bright red against a blue background. Gram-negative.

Cultivation: May be cultivated in plasma tissue cultures, in modified Maitland media and in the yolk sac of chick embryos.

Immunology: There is complete cross immunity between Australian and American strains of Q fever in guinea pigs. Strains from other parts of the world also cross immunize.

Serology: American and Australian strains are identical by agglutination and agglutinin absorption. Strains from various countries are serologically related as shown by complement fixation. Q fever is distinguishable from other rickettsial diseases by complement fixation tests. No common antigenic factor with any *Proteus* strain has been demonstrated.

Filterability: The infectious agent of Q fever readily passes Berkefeld N filters which are impermeable to ordinary bacteria and W filters which are impermeable to typhus and spotted fever rickettsiae.

Resistance to chemical and physical agents: Comparatively resistant to heat, drying and chemical agents. Survives at least 109 days in cell-free media without loss of titer, resistant to 60°C for 1 hour and to 0.5 per cent formalin and 1 per cent phenol when tested in fertile eggs.

Pathogenicity: Pathogenic for man, guinea pig and the white mouse. The monkey, dog, white rat and rabbit are mildly susceptible. Certain bush animals in Australia, particularly the bandicoot, are susceptible and these animals have been found naturally infected. Other rodents and marsupials are mildly susceptible. Calves have been experimentally infected and cows have been found recovered from naturally acquired infections.

A febrile reaction occurs in guinea pigs but mortality is low except with heavily infected yolk sac which causes a high mortality. On subcutaneous or intradermal inoculation a marked inflammatory thickening of the skin occurs at the site of inoculation. On autopsy the spleen is enlarged from 2 to 12 times by weight and is engorged with blood. Transfer in guinea pigs and mice is accomplished by transfer of infected liver and spleen. A febrile reaction often accompanied by pneumonitis occurs in man, but mortality is low.

Source: First seen in smears from mice inoculated intraperitoneally with infectious material by Burnet and Freeman (Med. Jour. Australia, *2*, 1937 (2), 281).

Habitat: The wood tick (*Dermacentor andersoni*) and the ticks, *Dermacentor occidentalis*, *Amblyomma americanum*, *Haemaphysalis leporis-palustris*, *Ixodes dentatus* and *Haemaphysalis humerosa*. Several other species of ticks have been shown to transmit experimentally the virus of Q fever. It has been found to survive in the ova of the female ticks (*Dermacentor andersoni* and *Haemaphysalis humerosa*). The bandicoot (*Isodon macrurus*) is probably the natural reservoir of the disease in Australia. The etiological agent of Q (Queensland) fever in man.

Genus III. Cowdria *Bengtson, gen. nov.*

Named for E. V. Cowdry who first described the organism in heartwater of three ruminants, sheep, goats and cattle.

Small pleomorphic, spherical or ellipsoidal, occasionally rod-shaped organisms, occurring intracellularly in ticks. Gram-negative. Have not been cultivated in cell-free media. Parasites which are the etiological agent of heartwater of cattle, sheep and goats.

The type species is *Cowdria ruminantium* (Cowdry) Bengtson.

1. **Cowdria ruminantium** (Cowdry) Bengtson, *comb. nov.* (*Rickettsia ruminantium* Cowdry, Jour. Exp. Med., *42*, 1925, 231; *Rickettsia* (*Cowdria*) *ruminantium* Moshkovsky, Uspekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), *19*, 1945, 18.) From M. L. *Ruminantia*, the cud-chewing mammals.

Differ morphologically from typical rickettsiae, showing usually spherical and ellipsoidal forms; occasionally bacillary forms. Irregular pleomorphic forms occur. Grow in the cytoplasm of cells, sometimes in densely packed masses. Size of cocci from 0.2 to 0.5 micron in diameter in the endothelial cells of animals, 0.2 to 0.3 micron in diameter in ticks. Bacillary forms 0.2 to 0.3 by 0.4 to 0.5 micron and pairs 0.2 by 0.8 micron in ticks. Non-motile.

Stain blue with the Giemsa stain and can also be stained by methylene blue and other basic aniline dyes. Gram-negative.

Cultivation not reported.

Immunology: Immunity incomplete after recovery from the infection. The organisms are found in the tissues long after recovery. There is some evidence of a variety of strains.

Pathogenicity: Pathogenic for goats, sheep and cattle. Transmissible to goats by inoculation of infected blood intrajugularly. The most characteristic lesion is the hydropericardium of infected animals. The only small animal shown to be susceptible is the ferret.

Source: Seen in the endothelial cells of renal glomeruli and in the endothelial cells of the cerebral cortex of animals suffering from heartwater and in the tick, *Amblyomma hebraeum*.

Habitat: The bont tick (*Amblyomma hebraeum*) and also *Amblyomma variegatum*. When the tick is infected in the larval state, it can transmit the infection to the nymphal and adult stages, but the disease is not transmissible through the ova of the adult female tick. The etiological agent of heartwater in sheep, goats and cattle in South Africa.

Appendix I: Further studies of the organism of trench fever are required before the relationship of *Rickettsia quintana* to the other more firmly established species of rickettsiae can be determined. Therefore, it is placed in this appendix.

1. *Rickettsia quintana* Schminke. (Schminke, Münch. med. Wchnschr., *64*, July 17, 1917, 961; *Rickettsia wolhynica* Jungmann and Kuczynski, Ztschr. klin. Med., *85*, 1918, 261; *Fossilis quintana* suggested as a possible subspecies "if necessary" by Megaw, Trop. Dis. Bull., *40*, 1943, 828.)

Probable synonym: *Rickettsia pediculi* Munk and da Rocha-Lima, Münch. med. Wchnschr., *64*, 1917, 1423.

Coccoid or ellipsoidal organisms, often occurring in pairs, more plump and staining more deeply with the Giemsa stain than *Rickettsia prowazekii*. Da Rocha-Lima gives their size as 0.2 to 0.4 micron by 0.3 to 0.5 micron. In lice appear as short rods, frequently in pairs and often bipolarly stained. Non-motile.

Stain reddish-violet with the Giemsa stain. Gram-negative. Occur extra-

cellularly in the region of the epithelial lining of the gut of the louse.

Cultivation: Has not been cultivated in tissue culture or any cell-free medium, though *Rickettsia pediculi*, considered by some identical with *Rickettsia quintana*, has been cultivated on human and horse blood agar.

Pathogenicity: Pathogenic for man, causing recurrent fever. No strain has been definitely established in laboratory animals.

Immunology: Partial immunity is produced after an attack of the disease. The disease is characterized by relapses which may occur as long as two years after the initial attack.

Distinctive characteristics: The organism resists a temperature of 60°C moist heat for 30 minutes or a dry heat at 80°C for 20 minutes. It resists desiccation in sunlight for 4 months. It is filterable under certain conditions but not when in plasma or serum. It is present in filtrates of infected vaccine sediments and excrements of infected lice.

Source: Seen in lice fed on trench fever patients by Töpfer (Münch. med. Wchnschr., *61*, 1916, 1495).

Habitat: The epithelial lining of the gut of the body louse (*Pediculus humanus* var. *corporis*) where they occur extracellularly, and *Pediculus capitis*. The virus is not transmissible through the ova. May be the etiological agent of trench fever (Wolhynian fever, shin bone fever, five-day fever).

Appendix II: Additional named species are included in Chapter V, *Rickettsiae*, in Steinhaus, Insect Microbiology. Ithaca, 1946, 304–328. Some differ morphologically and tinctorially from typical rickettsiae, some are not associated with an arthropod vector, some have been incompletely studied and described, some have been cultivated in cell-free media. Pending the completion of further studies involving possible cultivation in fertile eggs, the determination of biological properties, and adequate comparative immunological and serological studies, no attempt is made to classify these organisms. The descriptions are condensed from those given by Steinhaus:

Ehrlichia (*Rickettsia*) *kurlovi* Moshkovsky. (Compt. rend. Soc. Biol., Paris, *126*, 1937, 379; *Ehrlichia kurlovi* Moshkovsky, Uspekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), *19*, 1945, 12.) Found in the monocytes of guinea pigs. Described by Kurloff in 1889 as inclusions in the mononuclear cells of guinea pigs and other animals. These became known as Kurloff bodies. However, the parasitism of these bodies is questionable.

Rickettsia avium Carpano. (Riv. Pat. Comp., Jan.–Feb., 1936, 1.) Minute bodies in the leucocytes and tissue cells of a bullfinch (*Pyrrhula europea*) brought to Egypt from Germany. Donatien and Lestoquard (Arch. Inst. Pasteur Algérie, *15*, 1937, 142) suggested that this organism might have been that of psittacosis.

Rickettsia bovis Donatien and Lestoquard. (Donatien and Lestoquard, Bull. Soc. Path. Exot., *29*, 1936, 1057; *Ehrlichia bovis* Moshkovsky, Uspekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), *19*, 1945, 18.) Concerned in a disease of cattle which is transmitted by an unidentified tick of the genus *Hyalomma*. The organism occurs in circular or round-angled polygonal masses which consist of a large number of tightly pressed, minute spherical granulations. These masses are situated in the cytoplasm of various monocytes. The organism causes a relatively light febrile disease in cattle, and an inapparent infection in sheep and fever in monkeys.

Rickettsia canis Donatien and Lestoquard. (Donatien and Lestoquard, Bull. Soc. Path. Exot., *28*, 1935, 418; *Ehrlichia* (*Rickettsia*) *canis* Moshkovsky, Compt.

rend. Soc. Biol., Paris, *126*, 1937, 382; *Ehrlichia canis* Moshkovsky, Uspekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), *19*, 1945, 18.) Moshkovsky selects this species as the type species of the subgenus *Ehrlichia* Moshkovsky (*loc. cit.*). Found in dogs used for experimental purposes in Algeria. Appears to be transmitted naturally by the dog tick (*Rhipicephalus sanguineus*). All active stages of the tick transmit the organism and it passes intraovarially from the female to the larvae of the next generation. The organisms are generally spherical in shape and can be seen in the circulating monocytes. The infection causes a serious and often fatal illness in dogs. Small laboratory animals are not susceptible to the disease.

Rickettsia conjunctivae, *Rickettsia conjunctivae bovis* and *Rickettsia conjunctivae galli*, see Family III, *Chlamydozoaceae*.

Rickettsia ctenocephali Sikora. (Arch. Schiffs- u. Tropenhyg., *22*, 1918, 442.) Found in cat fleas (presumably *Ctenocephalides felis*) on the surface of the organs in the body cavity and in the coelomic fluid. Two forms were found which might be two species, one resembling *Rickettsia pediculi* and the other *Rickettsia melophagi*. Hertig and Wolbach (Jour. Med. Res., *44*, 1924, 329) found *Rickettsia ctenocephali* to vary in size and shape from minute cocci to rather large, swollen, curved rods, staining reddish with the Giemsa stain.

Rickettsia culicis Brumpt. (Ann. Parasitol. Hum. et Comp., *16*, 1938, 153.) Found in the stomach epithelium of mosquitoes (*Culex fatigans*) 12 days after they had been fed on a patient carrying *Microfilaria bancrofti*. Thought to be pathogenic for the mosquito and possibly for man. Occurs in the form of small granules and more often as small bipolar rods. Stains with haemalum, erythrosine-orange and toluidine blue. Gram-negative.

Rickettsia dermacentrophila Steinhaus. (Pub. Health Repts., *57*, 1942, 1375.) Found in all stages of the wood tick (*Dermacentor andersoni*). In the epithelial cells of the intestinal diverticula and other tissues of the tick, usually extracellularly but sometimes intracellularly. Not seen in the nuclei of cells. Gram-negative and staining red with the Machiavello stain, and bluish-purple with the Giemsa stain. Stains less deeply with ordinary bacterial stains than most bacteria. Resembles *Rickettsia rickettsii* morphologically but is slightly larger. Not pathogenic for laboratory animals or for some of the natural hosts of *Dermacentor andersoni*.

Rickettsia hirundinis Cowdry. (Jour. Exp. Med., *37*, 1923, 431.) An organism observed by Arkwright, Atkin and Bacot (Parasitology, *13*, 1921, 27) in the tissues of *Cimex hirundinis* which is probably the same organism to which Cowdry referred as *Rickettsia hirundinis*. Considered by Steinhaus as a *nomen nudum*.

Rickettsia kairo da Rocha-Lima. (Cairo rickettsia, Arkwright and Bacot, Brit. Jour. Exper. Path., *4*, 1923, 70; da Rocha-Lima, in Kolle and Wasserman, Handb. d. path. Mikroorg., 3 Aufl., *8*, 1930, 1361.) Resembles *Rickettsia rochalimae* and *Rickettsia prowazekii*.

Rickettsia lectularia Arkwright, Atkin and Bacot. (Parasitology, *13*, 1921, 27.) Found in the gut of the bedbug (*Cimex lectularius*) as filamentous and rod-shaped organisms. It seems probable that all bedbugs harbor the organism and it is also present in the developing ova. The location is intracellular. Very pleomorphic, ranging from small coccoid forms to thread-like forms. The small coccoid and diplococcoid forms stain deep purple with the Giemsa stain, while bacillary, lanceolate and thread forms stain more red than purple with the Giemsa stain. Not infective for small laboratory animals or for man.

Rickettsia linognathi Hindle. (Parasitology, *13*, 1921, 152.) Found in the

alimentary tract of the goat louse (*Linognathus stenopsis*). Resembles *Rickettsia trichodectae* morphologically and occurs only extracellularly in the lumen of the gut.

Rickettsia melophagi Nöller. (Arch. Schiffs- u. Tropenhyg., *21*, 1917, 53.) Found upon and in the cuticular layer covering the epithelium of the midintestine of the sheep tick (*Melophagus ovinus*). Occurs characteristically in pairs of fairly uniform size, coccoid and sometimes rod-shaped. Gram-negative but stains fairly well with carbol-fuchsin and gentian violet. Stains deep purple with Giemsa's method and bright red with Machiavello's method. Has been cultivated on non-living culture media, a glucose-blood-bouillon agar medium. The ability of *Rickettsia melophagi* to infect sheep has been the subject of contradictory claims. Small laboratory animals seem not to be susceptible.

Rickettsia ovina Lestoquard and Donatien. (Lestoquard and Donatien, Bull. Soc. Path. Exot., *29*, 1936, 108; *Ehrlichia ovina* Moshkovsky, Usphekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), *19*, 1945, 18.) Found in the blood of diseased sheep from Turkey and Algeria. The organisms occur as minute coccoid granules, grouped in masses and present only in the monocytes and never in endothelial cells. They stain uniformly dark red with the Giemsa stain but did not stain with the Castañeda technic. Infected ticks (*Rhipicephalus bursa*) are thought to be the vectors.

Rickettsia pisces Mohamed. (Ministry Agr., Egypt., Tech. Sci. Serv. Bull. 214, 1939, 6 pp.) In the monocytes and plasma of the blood of a fish (*Tetraodon fahaka*) showing necrotic ulcers on its head and both sides of the body. The heart, liver and intestines showed lesions. The organisms were minute coccoid forms varying from 0.2 to 0.4 micron in diameter and frequently occurring in pairs.

Rickettsia rocha-limae Weigl. (Przglad. Epidemj., *1*, 1921, 375.) Occurs in lice (*Pediculus humanus*) but is apparently non-pathogenic either to lice or to vertebrates. Larger and more pleomorphic than *Rickettsia prowazekii*. In smears or sections of the gut of lice, *Rickettsia rocha-limae* occurs in agglomerated masses, grouped like staphylococci. They occur both extracellularly and intracellularly and stain more deeply than *Rickettsia prowazekii*. Weigl claims to have cultivated this species on artificial culture media under anaerobic conditions. Not pathogenic for laboratory animals or man.

Rickettsia suis Donatien and Gayot. (Bull. Soc. Path. Exot., *35*, 1942, 324.) Causes a disease in swine, the pathology of which resembles heartwater of ruminants. See Genus III, *Cowdria*, Family *Rickettsiaceae*.

Rickettsia trichodectae Hindle. (Parasitology, *13*, 1921, 152.) In the species of biting lice (*Trichodectas pilosus*) which may be found on horses. This insect does not suck blood. The organisms occur extracellularly in the alimentary tract of the louse. The average size is 0.3 to 0.5 by 0.5 to 0.9 micron and occasionally longer forms occur.

Rickettsia weigli Mosing. (Arch. Inst. Pasteur, Tunis, *25*, 1936, 373.) Concerned in an epidemic disease which broke out in 1934 among employees of the Institute of Biology in Lwów who were engaged in feeding supposedly uninfected lice on their persons. Mosing and others have suggested the possibility that this rickettsia may be an extreme mutant of *Rickettsia pediculi*. Small coccoid to rod-shaped organisms staining well with the Giemsa stain, usually slightly longer than *Rickettsia prowazekii*. In the louse (*Pediculus humanus*), the rickettsiae occur extracellularly in the intestinal lumen forming a layer covering the surface of the epithelial lining. Not pathogenic for the louse as is *Rickettsia prowazekii* and *Rickettsia*

rocha-limae. It causes a febrile illness in man in which relapses occurred 3 to 5 times as in trench fever. *Rickettsia weigli* was agglutinated by convalescent sera but not by sera from typhus patients. Convalescent sera gave no positive Weil-Felix reaction.

Wolbachia pipientis Hertig. (Rickettsia of *Culex pipiens*, Hertig and Wolbach, Jour. Med. Res., *44*, 1924, 329; Hertig, Parasitology, *28*, 1936, 453.) This is the type species of the genus *Wolbachia* Hertig (*loc. cit*). Found in the ovaries or testes of the mosquito, and present in all stages o the mosquito's development. The outstanding morphological characteristic of the organism is great pleomorphism. Minute coccoids and short rods may be considered typical, but the usual microscopic field consists of various shapes and sizes. Some forms show bipolar staining with the Giemsa stain. The organism is a harmless parasite of the mosquito. Laboratory animals are apparently not susceptible.

The following unnamed rickettsiae isolated from animals or seen in animals are included in Steinhaus' list of rickettsiae (Insect Microbiology. Ithaca, 1946, 344):

A rickettsia was isolated by Parker, Kohls, Cox and Davis (Pub. Health Rept., *54*, 1939, 1482) from a tick (*Amblyomma maculatum*). It is pathogenic for guinea pigs and the disease is referred to as the maculatum disease. There is complete cross immunity in guinea pigs between this infection and Rocky Mountain spotted fever and boutonneuse fever, but it differs from these diseases in some particulars.

A rickettsia-like organism was isolated from the reduviid bug (*Triatoma rubrofasciata*) by Webb (Parasitology, *32*, 1940, 355). It was pathogenic for some laboratory animals and was maintained in guinea pigs for 5 passages. The rickettsiae were transmissible to the next generation through the egg of the reduviid bug.

A spotted fever type of rickettsia was isolated by Anigstein and Bader (Texas Repts. Biol. Med., *1*, 1943, 105) from the dog tick (*Rhipicephalus sanguineus*) taken from normal dogs. It was pathogenic for rabbits and guinea pigs.

A rickettsia was isolated by Anigstein and Bader (Texas Repts. Biol. Med., *1*, 1943, 298, 389) from ticks (*Amblyomma americanum*) collected in Texas. They believed it to be the cause of bullis fever.

Rickettsiae were observed by Enigh (Berl. u. Münch. Tierärztl. Wchnschr., 1942, 25) in the leucocytes of a bison calf. No arthropod was associated with this rickettsia.

A rickettsia-like agent pathogenic for guinea pigs was reported by Tatlock (Proc. Soc. Exp. Biol. and Med., *57*, 1944, 95). The animals had been injected with blood from a patient with "pretibial" fever. No arthropod vector was indicated.

Three species of rickettsia-like organisms isolated from the wood-tick (*Dermacentor andersoni*) are described by Noguchi (Jour. Exper. Med., *43*, 1926, 518–521). These were named *Bacillus rickettsiformis*, *Bacillus pseudoxerosis* and *Bacillus equidistans*. All could be cultivated on cell-free media and none was pathogenic for laboratory animals.

Appendix III: Unnamed rickettsia-like organisms seen in the tissues of insects.

Hertig and Wolbach (Jour. Med. Res., *44*, 1924, 329) list sixteen species of arachnids and twenty-three species of insects which are hosts to rickettsiae or rickettsia-like organisms.

Wolbach (Jour. Amer. Med. Assoc., *84*, 1925, 723) reports hosts of non-pathogenic rickettsiae which include fourteen species of arachnids (ticks, mites and spiders) and twenty-two species of insects distributed in nine orders, including

numerous non-blood-sucking insects as well as lice and ticks.

Cowdry (Arch. Path. and Lab. Med., *2*, 1926, 59) lists seven species of arachnids and twenty-four species of insects which are hosts to non-pathogenic rickettsiae.

Buchner, P. (Tier und Pflanze in Symbiose. Gebrüder Borntraeger, Berlin, 1930, 900 pp.) Through the text, and particularly on pages 300–664, the rickettsia-like and bacterium-like microorganisms occurring intracellularly in insects and other small animals are discussed, principally from the viewpoint of the biologist.

Paillot, A. (L'infection chez les Insects, Paris, 1933, 535 pp.). Concerned principally with bacterial infections of insects, but also includes information in intracellular symbiotes and rickettsia-like and bacterium-like microorganisms.

Steinhaus, Edward A. (Insect microbiology. Ithaca, 1946, 188–255.) Intracellular bacterium-like and rickettsia-like symbiotes are discussed.

FAMILY II. BARTONELLACEAE GIESZCZYKIEWICZ.*

(Bull. Intern. Acad. Polon. Sci., Classe Sci. Math. Nat., B (I), 1939, 9–30.)**

Small, often pleomorphic, rod-shaped, coccoid, ring-shaped, filamentous and beaded micro-organisms, staining lightly with aniline dyes, but well with Giemsa's stain. Gram-negative. Parasites of the erythrocytes in man and other vertebrates. Known to be transmitted by arthropod vectors in some cases. The causative organisms of bartonellosis in man, haemobartonellosis, grahamellosis and eperythrozoönosis in the lower animals. Differ from the protozoa that also parasitize erythrocytes in that the entire parasite stains with no differentiation into cytoplasm and nucleus.

Key to the genera of family **Bartonellaceae.**

1. Parasites of the erythrocytes and of fixed tissue in man.
   Genus I. *Bartonella*, p. 1100.
2. Parasites of the erythrocytes of lower mammals, increased in susceptible animals by splenectomy. Eradicated by arsenicals.
   Genus II. *Haemobartonella*, p. 1102.
3. Parasites of the erythrocytes of lower mammals. Not increased in susceptible animals by splenectomy. Not eradicated by arsenicals.
   Genus III. *Grahamella*, p. 1109.
4. Blood parasites, found on the erythrocytes and in the plasma of lower mammals. Appear as rings, coccoids and short rods. Splenectomy activates latent infections.
   Genus IV. *Eperythrozoon*, p. 1111.

Genus I. **Bartonella** *Strong, Tyzzer and Sellards.*

(*Bartonia* Strong, Tyzzer, Brues, Sellards and Gastiaburú, Jour. Amer. Med. Assoc., *61*, 1913, 1715; not *Bartonia* Muhlenberg, in Willdenow, Neue Schrift Ges. Nat. Fr., Berlin, *3*, 1801, 444; not *Bartonia* Sims, Bot. Mag., 1804; not *Bartonia* Crossman, Essais de Paleoconchologie Comparée, 4me Livr., Paris, 1901; Strong, Tyzzer and Sellards, Jour. Amer. Med. Assoc., *64*, 1915, 808; *emend.* Tyzzer and Weinman, Amer. Jour. Hyg., *30* B, 1939, 143.) Named for A. L. Barton who described these organisms in 1909.

Parasites of the erythrocytes which also multiply in fixed tissue cells. On the red blood cells in stained films, they appear as rounded or oval forms or as slender, straight, curved or bent rods occurring either singly or in groups. Characteristically in chains of several segmenting organisms, sometimes swollen at one or both ends and

---

* Prepared by Dr. Ida A. Bengtson (retired), National Institute of Health, Bethesda, Maryland and Dr. David Weinman, Parasitologist to the 1937 Harvard Expedition to Peru, Boston, Mass., April, 1947.

** Partial syn. *Anaplasmidae* has been proposed as a family name to unite the four genera *Anaplasma, Grahamella, Bartonella* and *Eperythrozoon* by Neitz, Alexander and du Toit (Onderst. Jour. Vet. Sci. and An. Ind., *3*, 1934, 268). Since the name is derived from *Anaplasma*, the nature of which is not fully understood and since these authors consider the 4 genera as belonging to the protozoan order *Haemosporidia*, it seems advisable not to consider this nomenclature for the present. The genus *Anaplasma* (parasites of the red blood cells of cattle) created by Theiler (Transvaal Govt. Vet. Bact. Rept. 1908–9, 7–64, 1910) consists of two species *Anaplasma marginale* and *Anaplasma centrale*. Recent workers are inclined to consider them to be bacterial in nature as they do not show a differentiation into cytoplasm and nucleus.

frequently beaded (Strong et al., *loc. cit.*, 1913), without a distinct differentiation of nucleus and cytoplasm. In the tissues they are situated within the cytoplasm of endothelial cells as isolated elements and grouped in rounded masses. These parasites occur spontaneously in man and in arthropod vectors, are endowed with independent motility, reproduce by binary fission, and may be cultivated by unlimited serial transfers on cell-free media. One species has been recognized. It is known to be established only on the South American continent and perhaps in Central America. Human bartonellosis may be manifested clinically by one of the two syndromes constituting Carrión's disease (Oroya fever or verruga peruana) or as an asymptomatic infection (definition by Strong, Tyzzer and Sellards *emend.* Tyzzer and Weinman (in Weinman, Trans. Amer. Philosoph. Soc., N.S., *33*, pt. 3, 1944, 246).

The type species is *Bartonella bacilliformis* (Strong et al.) Strong et al.

1. **Bartonella bacilliformis** (Strong, Tyzzer, Brues, Sellards and Gastiaburú) Strong, Tyzzer and Sellards. (*Bartonia bacilliformis* Strong et al., Jour. Amer. Med. Assoc., *61*, 1913, 1715; *Bartonella bacilliformis* Strong, Tyzzer and Sellards, Jour. Amer. Med. Assoc., *64*, 1915, 808; *emend.* Tyzzer and Weinman, Amer. Jour. Hyg. *30*(B), 1939, 143; also see Weinman, Trans. Amer. Philosoph. Soc., N.S., *33*, pt. 3, 1944, 246. Partial or complete synonyms: *Bartonella cocoide* (sic) Hercelles, Ann. de Fac. de Med., Lima, *9*, 1926, 231; *Bartonella peruviana* Escomel, Bull. Soc. path. Exot., *22*, 1929, 354; *Eperthyrozoon noguchii* Lwoff and Vaucel, Compt. rend. Soc. Biol., Paris, *103*, 1930, 975.) From Latin *bacillus*, rod and *forma*, shape.

Small, pleomorphic organisms, showing greatest morphological range in the blood of man, appearing as red-violet rods or coccoids situated on the red cells, when stained with Giemsa's stain. Bacilliform bodies are the most typical, measuring 0.25 to 0.5 by 1 to 3 microns. Often curved and may show polar enlargement and granules at one or both ends. Rounded organisms measure about 0.75 micron in diameter and a ring-like variety is sometimes abundant. On semi-solid media a mixture of rods and granules appear. The organisms may occur singly or in large and small, irregular dense collections, measuring up to 25 microns or more in length. Punctiform, spindle-shaped and ellipsoial forms of the organism occur, varying in size from 0.2 to 0.5 by 0.3 to 3 microns.

Gram-negative and non-acid-fast. Stain poorly or not at all with the usual aniline dye stains, but satisfactorily with Romanowsky and Giemsa stains.

Motile in the blood and in cultures. One to four unipolar flagella.

Cultivation: Growth in semi-solid agar with fresh rabbit serum and rabbit hemoglobin and in semi-solid agar with blood of man, horse or rabbit with or without the addition of fresh tissue and certain carbohydrates, in other culture media containing blood, serum or plasma, Huntoon's hormone agar at 20 per cent, semi-solid gelatin media, blood-glucose-cystine agar, chorio-allantoic fluid and yolk sac of chick embryo.

Gelatin not liquefied.

No acid or gas in glucose, sucrose, galactose, maltose, fructose, xylose, lactose, mannose, mannitol, dulcitol, arabinose, raffinose, rhamnose, dextrin, inulin, salicin and amygdalin.

No action on lead acetate.

Aerobic, obligate.

Optimum temperature 28°C.

Immunology: Natural immunity to infection has not been demonstrated in susceptible species. Acquired immunity apparent both during and after the disease. Bartonellae from different sources appear to provoke similar responses. Bartonellae from Oroya fever protect

against infection with organisms obtained from verruga cases.

Serology: Immune sera fix complement and agglutination of suspensions of *Bartonella* by sera from recovered cases has been reported.

Pathogenicity: Three forms of the disease occur in man; the anemic (Oroya fever), the eruptive (verruga peruana) and mixed types of both of the other forms. Experimental Oroya fever has not been successfully produced in animals, except rarely in an atypical form in monkeys. Experimental verruga peruana has been produced in man, in a number of species of monkeys and occasionally in dogs.

Source: Blood and endothelial cells of lymph glands, spleen and liver of human cases of Oroya fever.

Habitat: Blood and endothelial cells of infected man, probably also in sand flies (*Phlebotomus verrucarum* and *Phlebotomus noguchii*).

Genus II. **Haemobartonella** *Tyzzer and Weinman.*

(Amer. Jour. Hyg., *30*(B), 1939, 141.) From Greek *haemos*, blood and the generic name *Bartonella*.

Includes parasites of the red blood cells in which there is no demonstrable multiplication in the tissues and which do not produce cutaneous eruptions. They are typically rod- or coccoid-shaped, showing no differentiation into nucleus and cytoplasm, occurring naturally as parasites of vertebrates, and are transmitted by arthropods. They are distributed over the surface of the erythrocytes, and possibly sometimes within them. They stain well with Romanowsky type stains and poorly with other aniline dyes. Gram-negative. Not cultivated indefinitely in cell-free material. Rarely produce disease in animals without splenectomy, are markedly influenced by arsenotherapy, and are almost all of world-wide distribution. The experimental host range is restricted, infectivity of a rodent species for other rodents being common, but for primates unknown.

The type species is *Haemobartonella muris* (Mayer) Tyzzer and Weinman.

Key to the species of genus **Haemobartonella.**

I. The etiological agent of haemobartonellosis of the white rat.
   1. *Haemobartonella muris.*

II. The etiological agent of haemobartonellosis of the dog.
   2. *Haemobartonella canis.*

III. The etiological agent of haemobartonellosis of the vole.
   3. *Haemobartonella microtii.*

IV. The etiological agent of haemobartonellosis of the guinea pig.
   4. *Haemobartonella tyzzeri.*

V. The etiological agent of haemobartonellosis of cattle.
   5. *Haemobartonella bovis.*

VI. The etiological agent of haemobartonellosis of the buffalo.
   6. *Haemobartonella sturmanii.*

VII. The etiological agent of haemobartonellosis of the deer mouse.
   7. *Haemobartonella peromyscii.*

VIII. The etiological agent of haemobartonellosis of the gray-backed deer mouse.
   7a. *Haemobartonella peromyscii var. maniculati.*

IX. The etiological agent of haemobartonellosis of the short-tailed shrew.
   8. *Haemobartonella blarinae.*

X. The etiological agent of haemobartonellosis of the gray squirrel.
   9. *Haemobartonella sciurii.*

1. **Haemobartonella muris** (Mayer) Tyzzer and Weinman. (*Bartonella muris* Mayer, Arch. f. Schiffs.- u. Tropenhyg., *25*, 1921, 151; *Bartonella muris ratti* Regendanz and Kikuth, Compt. rend. Soc. Biol., Paris, *98*, 1928, 1578; Tyzzer and Weinman, Amer. Jour. Hyg., *30*(B), 1939, 143.) From Latin *mus*, *muris*, mouse.

Slender rods with rounded ends, frequently showing granules or swellings at one or both extremities, and dumbbell, coccoid or diplococcoid forms. May occur individually, in pairs, or in short chains of 3 or 4 elements, and, when abundant, in parallel grouping. The rods measure 0.1 by 0.7 to 1.3 microns and as much as half the length of a red cell. The coccoids have a diameter of 0.1 to 0.2 micron.

They have been found on and in the erythrocytes and in the plasma. Preferred stains are those of the Romanowsky type. With Giemsa's stain various investigators report an intense red coloration, a bluish tinge with distinct pink shading, blue with purple granules. With Wright's stain, the organisms stain bluish, with reddish granules at the ends. With Schilling's methylene blue-eosin stain the organisms stain a bright red color with the erythrocyte staining blue. They stain faintly with Manson's stain, pyronin-methyl green and fuchsin. Gram-negative.

There is lack of agreement concerning visibility in the fresh state and motility. Various authors report Brownian movement, slow and sinuous motion in the red cell or rapid motion.

Cultivation: Cultivated with difficulty and divergent results have been reported. Growth on various media reported (blood agar, agar with 2 per cent defibrinated rat blood, horse blood agar, N. N. N., Blutrösplatte of Wethmar, hormone agar with blood of rabbit, horse or man, ascitic fluid agar, chocolate agar, semi-solid rabbit serum agar, semi-solid rabbit blood agar, Noguchi-Wenyon medium, defibrinated rat blood, glucose broth, Tarozzi broth, peptone water) but usually growth was scant or could not be continued by transfer to the same medium or the organism isolated was non-infectious or the possibility of latent infections in the animal was not excluded. Best results are apparently obtained with semi-solid rabbit serum agar and semi-solid rabbit blood agar.

No conclusive results have been reported in tissue culture. The organism has been cultivated on the chorio-allantoic membrane of the chick embryo.

Filterability: Non-filterable with Seitz or Berkefeld N filters.

Immunology: No authentic case of true natural immunity in rats has been established. Acquired immunity occurs in (1) the latently-infected rat, (2) the infected rat after splenectomy and recovery from the disease, the period of resistance corresponding to the duration of latency, (3) the non-splenectomized non-carrier rat following infection, (4) animals other than the rat following infection.

Serology: No precipitins, thrombocytobarin, isoagglutinins, or cold hemolysins have been reported in the serum of anemic rats. Complement deviation and agglutination have been reported with sera from rabbits, rats and guinea pigs injected with cultures. Rabbits immunized with cultures have given positive Weil-Felix reactions with *Proteus* OX19 and OXK and rat sera recovered from haemobartonellosis have given a positive Weil-Felix reaction and positive agglutination in low dilution with *Rickettsia prowazekii*.

Pathogenicity: Infected blood, liver suspension, defibrinated laked blood, washed red cells, plasma and hemoglobinuric urine may produce infection by the subcutaneous, intravenous, intraperitoneal or intracardiac routes. Slight, transient or no haemobartonellosis occurs in adult non-splenectomized haemobartonella-free albino rats, adult non-splenectomized albino rats of carrier stock, adult splenectomized rats pre-

viously infected, until 15 weeks to 8 months after infection. Typical haemobartonellosis occurs in adult splenectomized haemobartonella-free albino rats and in young non-splenectomized haemobartonella-free albino rats weighing 20 to 30 grams at 3 weeks. Variable results have been obtained by different investigators with wild mice, guinea pigs, rabbits, hamsters, pigeons and monkeys (*Macacus rhesus* and *Macacus sp.*). It is known to be infectious for wild rats, albino mice, rabbits and for two Palestinian rodents (*Sphallax* (*Spalax* correct designation) *typhlops* and *Meriones tristrami*). Negative results have been reported in dogs, kittens, cats, sheep and various birds. Causes a definite and characteristic anemia without cutaneous eruption.

Arsenical therapy: True sterilization of latent or recognized infection with organic arsenical compounds.

Source: Blood of infected albino rats.

Habitat: Ectoparasites such as the rat louse (*Polyplax* (*Haematopinus*) *spinulosus*), the flea (*Xenopsylla cheopis*) and possibly the bedbug (*Cimex lectularius*). Also found in the erythrocytes of susceptible animals. World wide in distribution.

2. **Haemobartonella canis** (Kikuth) Tyzzer and Weinman. (*Bartonella canis* Kikuth, Klin. Wchnschr., 1928, 1729; Tyzzer and Weinman, Amer. Jour. Hyg., *30*(B), 1939, 151.) From Latin *canis*, dog.

One of the most pleomorphic of the haemobartonellae, occurring as thin rods, straight or slightly curved, dumbbell-shaped organisms, dots, coccoids, or rings. Chains of rods, coccoids or rings occur. These consist of only one type of these forms or a mixture of types. The chains may be straight, curved, branched or annular. Variable in size. Round forms vary from 0.2 or 0.5 micron to the limit of visibility. Single rods are 0.2 by 1 to 5 microns, while the composite forms vary from 1 to 4 microns. Situation is epi-erythrocytic.

Giemsa's fluid stains the organism red-violet, usually intensely. Methylene blue used as a vital stain colors the organism distinctly. Gram-negative and non-acid-fast.

Considered non-motile by most investigators.

Cultivation: Cultivation has not been demonstrated in semi-solid rabbit serum-agar medium nor in media containing serum of splenectomized dogs, N.N.N., Noguchi's medium for leptospira, blood broth, Chatton's medium covered with vaseline for *Trichomastix*.

Filterability: Results equivocal.

Immunology: The outstanding phenomena resemble those found in the rat infected with *Haemobartonella muris*.

Pathogenicity: Splenectomy is essential to infection accompanied by anemia in the dog. Negative results in splenectomized haemobartonella-free guinea pig, rat, rabbit, and monkey (*Cercopithecus sabaeus*). No infection or anemia in unoperated mice, white rats, young rabbits, young dogs and young guinea pigs. The splenectomized cat has been found to carry the infection by serial passage.

Arsenical therapy: Complete sterilization obtained by neoarsphenamine.

Source: Erythrocytes of infected splenectomized dogs.

Habitat: Found in dog fleas (*Ctenocephalus*) and erythocytes of infected animals. Distribution wide-spread, the infection occurring spontaneously in Europe, India, North and South Africa, North and South America.

3. **Haemobartonella microtii** Tyzzer and Weinman. (Tyzzer and Weinman, Amer. Jour. Hyg., *30*(B), 1939, 143; also see Weinman, Trans. Amer. Philosoph. Soc., N. S., *33*, 1944, 312; questionable synonym *Bartonella arvicolae* Yakimoff, Arch. Inst. Past. de Tunis, *17*, 1928, 350; *Haemobartonella arvicolae* Weinman, *loc.*

cit., 290.) From the genus of voles, *Microtus*.

In infected animal, morphology resembles that of *Haemobartonella canis*, the organisms occurring as rods, coccoids, filaments, club forms, ring forms and granular masses. In addition to these forms there occur in Giemsa-stained blood films ovoids, diamond- or flame-shaped small forms as well as coarse segmented or unsegmented filaments up to 5 microns in length. Filaments may contain one or more rings, or may be composed in part or entirely of diamond-shaped, coccoid or ovoid elements, sometimes in parallel rows. Rods often show intense bipolar staining. Coccoid forms, usually scattered, may occur as aggregates or clumps on the red cell, apparently embedded in a faint blue matrix.

A pale blue veil-like substance may cover nearly half of one surface of the red cells and show at its border typical red-violet stained rods or filaments in the Giemsa-stained specimens. A bow-shaped arrangement of elements is characteristic. Organisms lie on the surface of the red cells. In cultures organisms are more uniform in morphology resembling *Bartonella bacilliformis*. Individual organisms are fine rods, 0.3 by 1.0 to 2 microns, sometimes occurring in chains and often in clumps. Small round forms occur, measuring 0.5 micron in diameter, and occasionally round disk-like structures.

Cultivation: Growth in Noguchi's semi-solid serum agar 2 weeks after inoculation with citrated or heparinized blood and incubated at 23°C shows as white rounded masses, measuring up to about 1 mm in the upper 15 mm of the tube. In tissue culture the organism grows in small, rounded compact masses within the cytoplasm of infected cells. Indefinite maintenance of the strains isolated on artificial media has not been possible.

Pathogenicity: Splenectomized white mice and splenectomized laboratory reared voles are readily susceptible to infection. No marked anemia or any mortality in heavily infected animals. Splenectomized dogs, white rats and deer mice are not susceptible.

Source and habitat: Erythrocytes of the vole (*Microtus pennsylvanicus pennsylvanicus*) following splenectomy. The natural mode of transmission has not been determined though ticks or mites are suspected.

4. **Haemobartonella tyzzeri** (Weinman and Pinkerton) Weinman. (*Bartonella tyzzeri* Weinman and Pinkerton, Ann. Trop. Med., *32*, 1938, 217; Weinman, Trans. Amer. Philosoph. Soc., *33*, 1944, 314.) Named for Prof. Tyzzer who studied haemobartonellae.

Single or composite rods from about 0.25 micron by 1.4 to 4.0 microns. Occasional granular swellings and enlarged poles. Short rods also occur averaging 0.2 to 0.3 by 0.8 micron and also round forms with diameters of 0.2 to 0.3 micron. Distributed irregularly in the red cells.

Stain intensely red-violet with Giemsa's or May-Grünwald-Giemsa's solutions. Gram-negative.

Cultivation: Initial cultures on Noguchi's semi-solid serum agar obtained irregularly. When incubated at 28°C, colonies appear as isolated white spheres about 1 mm in diameter in the upper 8 mm border of the medium. The clumps are composed of rods and granules, with larger round structures or disks occurring occasionally. Also cultivated on the Zinsser, Wei and Fitzpatrick modification of the Maitland medium. Prolonged maintenance on semi-solid media has not been obtained.

Pathogenicity: Splenectomized haemobartonella-free guinea pigs may be infected by blood or cultures injected subcutaneously or intraperitoneally. Splenectomized *Haemobartonella muris*-free rats are insusceptible when inoculated with infected guinea-pig blood. *Macacus rhesus* monkeys are also in-

susceptible to inoculations of infected blood, tissue and cultures. Infection of the guinea pig is subclinical in its manifestations, probably due to the small number of parasites in the blood. No definite anemia accompanies infection.

Source and habitat: Erythrocytes of the Peruvian guinea pig (*Cavia porcellus*). Has also been encountered in Colombia but not in other parts of the world. Observed in latently infected animals only after splenectomy. The natural mode of transmission is unknown, though the flea may be a possible vector.

5. **Haemobartonella bovis** (Donatien and Lestoquard) Weinman. (Donatien and Lestoquard, Bull. Soc. Path. Exot., *27*, 1934, 652; *Bartonella sergenti* Adler and Ellenbogen, Jour. Comp. Path. and Therap., *47*, 1934, 221; (?) *Bartonella bovis* Rodriguez, Rev. del Inst. Llorente, *13*, 1935, 5; abst. in Bull. Inst. Past., *34*, 1936, 1033; Weinman, Trans. Amer. Philosoph. Soc., N. S., *33*, 1944, 308; *Haemobartonella sergenti* Weinman, *loc. cit.*, 290.) From Latin *bos, bovis*, ox.

Resembles *Haemobartonella muris* and *H. canis*. Occurs as rods, coccobacilli and cocci, singly, in pairs or short chains or groups of 10 or more elements. The rods measure 1.2 to 2 microns in length and are very slender. The coccobacilli occur singly or in pairs measuring 0.3 by 0.6 to 0.8 micron and the diameters of the cocci are about 0.3 micron. The parasite may occupy a central or marginal position on the red cell; the number on a cell varying from 1 to 20. Not more than 20 per cent of the cells are parasitized.

Using the Romanowsky stain, the organisms stain similarly to the chromatin of *Piroplasma spp.*

Source and habitat: In the blood of bulls in Algeria and in a non-splenectomized calf in Palestine.

6. **Haemobartonella sturmanii** Grinberg. (Grinberg, Ann. Trop. Med., *33*, 1939, 33; Weinman, Trans. Amer. Philosoph. Soc., N. S., *33*, 1944, 313.)

Similar to *Haemobartonella bovis* and *H. canis* in morphology and staining properties. Occurs as rods, cocco-bacillary and coccoid forms, varying in length from 0.5 to 1.5 microns. The number of parasites per infected cell varies from 1 to 15 and they occur individually, scattered irregularly in clumps or sometimes in chains stretching across the cell. At the height of the infection more than 90 per cent of the cells are infected.

Pathogenicity: Causes a temperature rise in buffaloes and slight anemia after direct blood inoculation. Splenectomized rabbits, hamsters and splenectomized calves inoculated with blood from infected buffaloes remained free of the parasite.

Source and habitat: In the blood of buffaloes in Palestine.

7. **Haemobartonella peromyscii** Tyzzer. (Proc. Amer. Philos. Soc., *85*, 1942, 377.) Named for the genus of deer mice, *Peromyscus*.

Occurs as delicate filamentous forms (which may be branched) on the red blood cells. These filaments may become beaded and give rise to a number of coccoids and rods from which ring forms may develop.

Stains by Giemsa's method, but staining process must be intense in order to demonstrate the organism.

Pathogenicity: Infection transmissible to splenectomized white rats, white mice and voles, producing a more or less severe illness with anemia.

Habitat: In the blood of the deer mouse (*Peromyscus leucopus noveboracensis*).

7a. *Haemobartonella peromyscii* var. *maniculati* Tyzzer. (Proc. Amer. Philos. Soc., *85*, 1942, 381.) Named for the species of mouse from which it was isolated.

Occurs as rods and filamentous

branched forms. Coarser filaments appear to rise from rounded granules. Delicate rods are preponderant, and minute coccoids appear occasionally. When transferred to the common deer mouse, coarser forms appear, including filaments and large coccoids, sometimes in chains.

Pathogenicity: Pathogenic for gray-backed deer mice and the common deer mouse, but non-infective for splenectomized white mice.

Habitat: Blood of the gray-backed deer mouse (*Peromyscus maniculatus gracilis*).

8. **Haemobartonella blarinae** Tyzzer. (Proc. Amer. Philos. Soc., *85*, 1942, 382.) Named for the genus of shrews, *Blarina*.

Extremely pleomorphic with delicate rods and coccus-like forms, often occurring in chains which also contain larger elements which have a deeply stained, bead-like granule. In the early stages of infection they may occur as thick bands or filaments stretching over the red cells usually with a bead or granule.

The bands take a bluish tint with Geimsa's stain, while the more delicate form stains a slaty violet. The head is distinctly reddish. In the fully developed infection, rods and filaments predominate over rounded forms. The organisms may be scattered on the surface of the red cells or may form a dense cap which is intensely stained. Rudimentary mycelia may be found radiating from a central portion and reddish stained material with ill-defined contours may occur at the ends of the mycelial branches.

Pathogenicity: Pathogenic for the short-tailed shrew but not for deer mice or white mice. Causes anemia in the shrew.

Habitat: In the blood of the short-tailed shrew (*Blarina brevicauda*).

9. **Haemobartonella sciurii** Tyzzer. (Proc. Amer. Philos. Soc., *85*, 1942, 385.) Named for the genus of gray squirrels, *Sciurus*.

Very pleomorphic. Occurs as minute rods and filaments which are continuous or segmented. The rods and filaments vary in thickness, some are very uneven and some very coarse. Beaded chains may develop from the thickened forms.

The bead-like elements stain a dull reddish at the periphery with Giemsa's stain while the remainder is very faintly stained in contrast to the intensely staining basophilic rods and filaments. Some of the rounded forms have the appearance of large, thick rings. Beads and rings may arise from slender deeply staining rods, simulating very closely spores within bacilli, though no germination of filaments from them has been observed.

Pathogenicity: Slightly pathogenic for the gray squirrel, non-pathogenic for normal white mice.

Habitat: Blood of the gray squirrel (*Sciurus carolinensis leucotis*).

Appendix: Here are included (1) *Haemobartonella* of undetermined specific rank, (2) *Haemobartonella*-like structures in non-splenectomized mammals and in cold-blooded animals, (3) Invalid species (see Weinman, Trans. Amer. Philosoph. Soc., N. S., *33*, 1944, 315).

1. Hameobartonellae of undetermined specific rank. Microorganisms are grouped according to host of origin and are considered to be haemobartonellae from the description of the original author; but the information furnished is not sufficient for further classification.

Haemobartonellae similar to *Haemobartonella muris* in wild rats: *Mus decumanus*, *Mus norvegicus*, *Rattus rattus frugivorus*, *Mus rattus griseiventer*, *Mus rattus rattus*, *Mus sylvaticus*. In various rats; technical names not given.

Haemobartonellae similar to *Haemobartonella muris* in albino mice. Schilling (Klin. Wchnschr., 1929, 55) separated the haemobartonella of the mouse from

that of the rat and named it *Bartonella muris musculi* var. *albinoi* (*Haemobartonella muris musculi* var. *albinoi* Weinman, *loc. cit.*, 290).

Haemobartonellae similar to *Haemobartonella muris* in other mammals: *Haemobartonella glis glis* (Kikuth) Weinman (*Bartonella glis glis* Kikuth, Cent. f. Bakt., I Abt., *123*, 1931, 356; Weinman, *loc. cit.*, 317) in dormice (*Glis glis*).

Haemobartonella opossum (Regendanz and Kikuth) Weinman (*Bartonella opossum* Regendanz and Kikuth, Arch. f. Schiffs- u. Tropenhyg., *32*, 1928, 587; Weinman, *loc. cit.*, 290) in the marsupial rat (*Metachirus opossum*) and in the opossum (*Didelphys didelphys*).

Haemobartonella spp. in *Lophuromys ansorgei*, in *Lophuromys laticeps*, in *Oenomys bacchante editus*, in *Praeomys jacksoni*, in *Arvicanthus striatus*, in deer mouse (*Peromyscus leucopus novaboracensis*), in Chinese hamsters (*Cricetulus griseus*, *Cricetulus griseus fumatus*), in *Apodemus agrarius* and *Phodopus praedilectus*), and in squirrels (*Sciurus vulgaris*). Mixed infections, including haemobartonellae are found in jerboa, the gerbille and various rodents (see Weinman, *loc. cit.*, 317–319).

2. Haemobartonella-like structures in non-splenectomized mammals and cold-blooded animals.

Various bodies whose proper classification in the genus *Haemobartonella* has not been established (Weinman, *loc. cit.*, 319)

In non-splenectomized mammals:

Bartonella melloi Yakimoff and Rastegaieff, Bull. Soc. Path. Exot., *24*, 1931, 471 (*Haemobartonella melloi* Weinman, *loc. cit.*, 290) in the ant eater (*Manis pentadactyla*).

Bartonella pseudocebi Pessôa and Prado, Rev. biol. e hyg., *1*, 1927, 116 (*Haemobartonella pseudocebi* Weinman, *loc. cit.*, 290) in the monkey (*Pseudocebus apella*).

Bartonella rocha-limai Faria and Pinto, Compt. rend. Soc. Biol., Paris, *95*, 1926, 1500 (*Haemobartonella rocha-limai* Weinman, *loc. cit.*, 290) in the bat (*Hemiderma brevicauda*).

Bartonella sp. in the rat (*Rattus rufescens*) and *Bartonella sp.* in the dormouse (*Myoxus glis*).

In cold-blooded animals:

Bartonella pavlovskii Epstein, All Union. Inst. Exper. Med., Moscow, 1935, 398, see Ray and Idnani, Indian Jour. Vet. Sci. and Animal Husb. *10*, 1940, 259, (*Haemobartonella pavlovskii*, Weinman *loc. cit.*, 290) in the lamprey (*Petromyzon marinus*).

Bartonella nicollei Yakimoff, Arch. Inst. Pasteur Tunis, *17*, 1928, 350 (*Haemobartonella nicollei* Weinman, *loc. cit.*, 290) in the brochet (*Esox lucius*).

Bartonella ranarum da Cunha and Munez, Compt. rend. Soc. Biol., Paris, *97*, 1927, 1091 (*Haemobartonella ranarum* Weinman, *loc. cit.*, 290) in the frog (*Leptodactylus ocellatus*). This is probably identical with *Bartonella batrachorum* Zavattari, Boll. d. Soc. ital. biol. sper., *6*, 1931, 121 (*Haemobartonella batrachorum* Weinman, *loc. cit.*, 290) from the same species.

Bartonella sp. in the gecko (*Platydactylus mauritanicus*), *Bartonella sp.* in the lizard (*Lacertilia sp.*), *Bartonella sp.* in the lizard (*Tropidurus peruvianus*), *Bartonella sp.* in the tench (*Tinca tinca*) and *Bartonella sp.* in the tortoise (*Testudo graeca*).

3. Invalid species:

Bartonella caviae Campanacci, Ateneo parmense, *1*, 1929, 99 (*Haemobartonella caviae* Weinman, *loc. cit.*, 290) from the guinea pig.

Bartonella ukrainica Rybinsky, Rev. Microbiol. epidem. et parasitol., *8*, 1929, 296 (*Haemobartonella ukrainica* Weinman, *loc. cit.*, 290) from the guinea pig.

Weinman (*loc. cit.*, 314) states that the parasitism of these structures was not proven and no illustrations are furnished by the authors.

Genus III. Grahamella *Brumpt.*

(Brumpt, Bull. Soc. Path. Exot., *4*, 1911, 514; *Grahamia* Tartakowsky, Trav. IX^e Cong. Int. Med. Vet., *4*, 1910, 242; not *Grahamia* Theobald, Colonial Office, Misc. Pub. No. 237, 1909.) Named for G. S. Graham-Smith who discovered the parasite in the blood of voles.

Parasites occurring within the erythrocytes of the lower mammals which morphologically bear a resemblance to *Bartonella*, but which are less pleomorphic, more plump, and more suggestive of the true bacteria. They stain more deeply than bartonellae with Giemsa's stain, stain lightly with aniline dyes and with methylene blue. They are Gram-negative, non-acid-fast and non-motile. Splenectomy has no effect on the source of infection except in rats. They are non-pathogenic and not affected by arsenicals. Several species have been cultivated on cell-free media.* The etiological agent of grahamellosis of rodents and some other vertebrates.

The type species is *Grahamella talpae* Brumpt.

1. **Grahamella talpae** Brumpt. (Bull. Soc. Path. Exot., *4*, 1911, 514.) Named for the genus of moles, *Talpa*.

Long or short rods of irregular contour lying within the red blood cells, many with a marked curve, often near one of the extremities. One or both ends of the longer forms enlarged, giving a wedge- or club-shaped appearance. Some of the medium-sized forms definitely dumbbell-shaped, small forms nearly round.

With Giemsa's stain, the protoplasm of the organism stains light blue, with darker areas at the enlarged ends. Dark staining areas of longer forms give the organism a banded appearance. Length varies from 0.1 to 1 micron. Parasites occasionally free in the plasma, but usually in groups. Most of the infected corpuscles contain between 6 and 20 parasites (Graham-Smith, Jour. Hyg., *5*, 1905, 453).

Pathogenicity: Pathogenic for moles.

Appendix: In addition to *Grahamella talpae* Brumpt, descriptions of the following species occur in the literature. The list may not be complete and the validity of these species may be questioned in some cases.

Grahamella acodoni Carini. (Ann. Parasit., *2*, 1924, 253.) From *Acodon serrensis*, Brazil.

Grahamella alactagae Tartakowsky. (Katalogue der Exponaten der Landwirthschaftlichen Ausstellung (Russisch), St. Petersburg, 1913.) From *Alactaga saliens* and *Alactaga aconitus* in Transcaucasia and steppes of Astrakhan (*Alactaga* misspelled *Alactoga*). Quoted from Yakimoff, Arch. f. Protistenk., *66*, 1929, 303.

Grahamella arvalis Tartakowsky. (Katalogue der Exponaten der Landwirthschaftlichen Ausstellung (Russisch) St. Petersburg, 1913.) From *Microtus arvalis* in Transcaucasia. Quoted from Yakimoff, Arch. f. Protistenk., *66*, 1929, 304.

Grahamella balfourii Brumpt. (*Grahamella sp.* Balfour, Rept., Wellcome Tropical Research Laboratory, *2*, 1906, 97; *Grahamella balfouri* Brumpt, Bull. Soc. Path. Exot., Paris, *4*, 1911, 517.) From the desert rat (*Jaculus jaculus*) in the Sudan.

---

* Tyzzer (Proc. Amer. Philos. Soc., *85*, 1942, 375) finds that grahamellae isolated in culture show a close relationship to *Streptobacillus moniliformis* (*Actinomyces muris*) and proposes the inclusion of the genus *Grahamella* in the family *Actinomycetaceae*. The latter relationship appears to be very doubtful.

Grahamella blarinae Tyzzer. (Proc. Amer. Philos. Soc., *85*, 1942, 370.) From the short-tailed shrew (*Blarina brevicauda*) in Massachusetts.

Grahamella bovis Marzinowsky. (Med. Obosrenie, 1917, No. 1–2.) From the ox (*Bos taurus*) in Russia. Quoted from Yakimoff, Arch. f. Protistenk., *66*, 1929, 304.

Grahamella brumptii Ribeyro and del Aquilla. (Ann. Fac. Med., Lima, *1*, 1918, 14–20.) From *Desmodus rufus* in Peru.

Grahamella canis lupus Kamalow. (Cent. f. Bakt., I Abt., Orig., *128*, 1933, 197.) From the wolf, Tiflis.

Grahamella couchi Neitz. (Onderst. Jour. Vet. Sci. and An. Ind., *10*, 1938, 29.) From the multimammate mouse (*Mastomys coucha*) in South Africa.

Grahamella criceti domestici Parzwanidze. (Das Material zum Hämoparasitismus der Tiere bei Uns. Tiflis, 1925.) From *Cricetus domesticus* in Transcaucasia. Quoted from Yakimoff, Arch. f. Protistenk., *66*, 1929, 304.

Grahamella criceluli Patton and Hindle. (Proc. Roy. Soc., London, B(*100*), 1926, 387.) From *Cricetulus griseus* in China.

Grahamella dschunkowskii Tartakowsky. (*Grahamia sp.*, Dschunkowsky and Luhs, Trav. IX. Cong. Internat. Med. Vet., 1909, 4, 1910, 242; *Grahamia dschunkowski* Tartakowsky, 1910.) From the bat (*Vespertilio noctula*) in Transcaucasia. Ref. to Tartakowsky quoted from Yakimoff, Arch. f. Protistenk., *66*, 1929, 304.

Grahamella dudtschenkoi Yakimoff. (*Grahamella sp.*, Dudtschenko, Cent. f. Bakt., I Abt., Orig., *74*, 1914, 241; *Grahamella dudtschenkoi* Yakimoff, Arch. f. Protistenk., *66*, 1929, 304.) From the hamster (*Cricetulus sp.*) in Transbaikal.

Grahamella ehrlichii Yakimoff. (*Grahamella ehrlichi* Yakimoff, Arch. f. Protistenk., *66*, 1929, 305.) From the perch (*Perca fluviatilis*) in Russia.

Grahamella francai Brumpt. (*Grahamella sp.* Franca, Arch. Inst. Bacter. Camara, Pestana, *3*, 1911, 277; *Grahamella francai* Brumpt, Précis de Parasitologie, 2éme éd., 1913, 102.) From the jumping rat (*Eliomys quercinus*) in Portugal.

Grahamella gallinarum Carpano. (Ann Parasit. hum. et comp., *13*, 1935, 238.) From leghorn chickens in Egypt.

Grahamella gerbilli Sassuchin. (*Grahamia gerbilli* Sassuchin, Arch. f. Protistenk., *74*, 1931, 526.) From *Gerbillus tamaricinus* in southeast Russia.

Grahamella hegneri Sassuchin. (*Grahamia hegneri* Sassuchin, Arch. f. Protistenk., *75*, 1931, 152.) From *Citellus pygmaeus* in Russia.

Grahamella joyeuxii Brumpt. (*Grahamella sp.*, Joyeux, Bull. Soc. Path. Exot., Paris, *6*, 1913, 614; *Grahamella joyeuxi* Brumpt, Précis de Parasitologie, 2éme éd., 1913, 102.) From *Golunda fallax* and *Mus rattus* in French Guinea.

Grahamella merionis Adler. (Trans. Roy. Soc. Trop. Med., *24*, 1930, 78.) From *Meriones tristrami* in Palestine.

Grahamella microti Lavier. (Bull. Soc. Path. Exot., Paris, *14*, 1921, 573.) From *Microtus arvalis* in France.

Grahamella microti pennsylvanici Tyzzer. (Proc. Amer. Philos. Soc., *85*, 1942, 366.) From the common vole (*Microtus pennsylvanicus pennsylvanicus*) in Massachusetts.

Grahamella muris Carini. (Bull. Soc. Path. Exot., Paris, *8*, 1915, 104.) From the house rat (*Mus decumanus*) in Brazil.

Grahamella muris musculi iberica Parzwanidze. (Das Material zum Hämoparasitismus der Tiere bei uns. Tiflis, 1925.) From *Mus musculus* in Transcaucasia. Quoted from Yakimoff, Arch. f. Protistenk., *66*, 1929, 304.

Grahamella musculi Benoit-Bazille. (Bull. Soc. Path. Exot., Paris, *13*, 1920, 408.) From *Mus musculus* var. *albinos* in France.

Grahamella ninae kohl-yakomovi Yakimoff. (Bull. Soc. Path. Exot., Paris, *10*,

1917, 99.) From the hamster (*Cricetus phoca*) in Transcaucasia.

Grahamella peromysci Tyzzer. (Proc. Amer. Philos. Soc., *85*, 1942, 363.) From the deer mouse (*P. leucopus noveboracensis*) in Massachusetts.

Grahamella peromysci var. *maniculati* Tyzzer. (Proc. Amer. Philos. Soc., *85*, 1942, 365.) From the gray-backed deer mouse (*Peromyscus maniculatus*) in Massachusetts.

Grahamella phyllotidis Tyzzer. (Proc. Amer. Philos. Soc., *85*, 1942, 371.) From the Peruvian mouse (*Phyllotis darwini linatus*).

Grahamella pipistrelli Markow. (*Grahamia pipistrelli* Markow, Russian Jour. Trop. Med., 1926, No. 5, 52.) From the bat (*Pipistrellus nathusii*) in Russia.

Grahamella rhesi Leger. (Bull. Soc. Path. Exot., Paris, *15*, 1922, 680.) From the monkey (*Macacus rhesus*) in Annam.

Grahamella sanii Cerruti. (Arch. Ital. Sci. Med. Col., *11*, 1930, 522.) From *Testudo graeca* in Sardinia.

Grahamella talassochelys Cerruti. (Arch. Ital. Sci. Med. Col., *12*, 1931, 321.) From *Tallasochelys caretta* in Sardinia. (Misspelled for *Thalassochelys*.)

Genus IV. **Eperythrozoon** *Schilling.**

(Schilling, Klin. Wchnschr., 1928, 1854; *Gyromorpha* Dinger, Nederl. tijdschr. geneesk., *72*, 1928, 5903.) From Greek meaning animal on red blood cell.

Microscopic blood parasites found in the plasma and on the erythrocytes. They stain well with Romanowsky type dyes, and then appear as rings, coccoids or short rods, 1 to 2 microns in greatest dimension, staining bluish or pinkish violet. They show no differentiation of nucleus and cytoplasm. The organisms are not known to retain the violet in Gram's method or to be acid-alcohol-fast. Splenectomy activates latent infection. Not cultivated in cell-free media. Arthropod transmission has been established for one species (Weinman, Trans. Amer. Philosoph. Soc., N.S. *33*, pt. 3, 1944, 321).

The type species is *Eperythrozoon coccoides* Schilling.

Key to the species of genus **Eperythrozoon.**

I. Etiological agent of eperythrozoönosis of white mice.
  1. *Eperythrozoon coccoides.*

II. Etiological agent of eperythrozoönosis of sheep.
  2. *Eperythrozoon ovis.*

III. Etiological agent of eperythrozoönosis of cattle.
  3. *Eperythrozoon wenyonii.*

IV. Etiological agent of eperythrozoönosis of gray-backed deer mice.
  4. *Eperythrozoon varians.*

V. Etiological agent of eperythrozoönosis of voles and dwarf mice.
  5. *Eperythrozoon dispar.*

---

* This genus has been considered as belonging to the *Protozoa* by Neitz, Alexander and Du Toit (Onderst. J. Vet. Sci., *3*, 1934, 268) and to the bacteria by Mesnil (Bull. Soc. Path. exot., *22*, 1929, 531 and by Tyzzer (in Weinman, Trans. Amer. Philosoph. Soc., N.S., *33*, pt. 3, 1944, 244). The evidence at hand favors the inclusion of this group among those organisms which are not protozoan in nature but which are closely related to bacteria.

1. **Eperythrozoon coccoides** Schilling. (Schilling, Klin. Wchnschr., 1928, 1854; *Gyromorpha musculi* Dinger, Nederl. tijdschr. geneesk., *72*, 1928, 5905.) From Greek, coccus-shaped.

In stained blood films these organisms appear as rings, coccoids and rods, the majority as rings of regular outline with clear centers. They are in the plasma and on the red cells. Measure 0.5 to 1.4 microns in greatest dimension.

Stain pale red or reddish-blue with the Giemsa or the May-Grünwald-Giemsa technics. Gram-negative.

Suggested methods of multiplication by binary fission, budding, development of small coccoidal to annular forms.

Cultivation: Negative results.

Immunology: Immunological state in animals that of the premunition type. Latent infection in mice which is made manifest by splenectomy.

Pathogenicity: Pathogenic for white mice, rabbits, white rats, wild mice, usually in young animals or in splenectomized adults.

Source: Blood of splenectomized white mice.

Habitat: Blood of infected animals, mouse louse (*Polyplax serrata*) and probably other arthropods.

2. **Eperythrozoon ovis** Neitz, Alexander and Du Toit. (Neitz et al., Address, Biological Society, Pretoria, Mar. 15, 1934; from Neitz, Onderst. Jour. Vet. Sci. and An. Ind., *9*, 1937, 9.) From Latin *ovis*, sheep.

Delicate rings approximately 0.5 to 1.0 micron in diameter though occasionally larger. In addition there are triangles with rounded angles, ovoid, comma, rod, dumbbell and tennis racket forms. Found supra-cellularly on the erythrocytes but often free. Colored pale purple to pinkish-purple with Giemsa's stain. Suggested mode of multiplication by budding.

Cultivation: Negative results.

Immunology: Immunological state in sheep appears to be that of the premunition type.

Pathogenicity: Sheep, antelopes and probably goats and splenectomized calves are susceptible. Dogs, rabbits and guinea pigs are refractory. The distinctive feature of *Eperythrozoon ovis* is its ability to provoke illness in normal animals without resorting to splenectomy.

Source: Blood of infected South African sheep.

Habitat: Blood of infected animals. No ectoparasites found on sheep naturally infected, but an arthropod is suspected.

3. **Eperythrozoon wenyonii** Adler and Ellenbogen. (Adler and Ellenbogen, Jour. Comp. Path. and Therap., *47*, 1934 (Sept. 3), 220; see *Bartonella wenyoni* in appendix.) Named for Dr. C. M. Wenyon, a student of these organisms.

Morphologically similar to *Eperythrozoon coccoides*. Coccoid and often vesicular, staining pale red with Giemsa's stain and varying from 0.2 to 1.5 microns in diameter. Multiplication seems to be by budding and fission, and by filamentous growths from the ring forms, suggesting resemblance to *Hyphomycetes*. Up to 50 or 60 parasites are found on one cell. These are arranged in irregular chains or in tightly packed groups.

Cultivation not reported.

Immunology: The organism creates a state of premunition and latent infection is made manifest by splenectomy.

Pathogenicity: Cattle are susceptible, but sheep are not infected either before or after splenectomy.

Source: Blood of infected cattle.

Habitat: Blood of infected cattle, arthropod transmission not proven.

4. **Eperythrozoon varians** Tyzzer. (Proc. Amer. Philos. Soc., *85*, 1942, 387.) From Latin *varians*, varying.

Occur in rings, coccoids of varying size, some very minute, bacillary forms.

Many of the bacilliform elements show an unstained lens-like swelling, indicating the formation of a ring within the substance of the rod. At the height of the infection most of the organisms are found in the plasma. Whenever an organism comes in contact with a red cell, it stains intensely.

Pathogenesis: Pathogenic for the gray-backed deer mouse (causing anemia) and for the splenectomized common deer mouse. Not pathogenic for splenectomized white mice.

Habitat: Blood of the gray-backed deer mouse (*Peromyscus maniculatus gracilis*).

5. **Eperythrozoon dispar** Bruynoghe and Vassiliadis. (Ann. de Parasitol., 7, 1929, 353.)

Resembles *Eperythrozoon coccoides* in staining, distribution on the erythrocytes and also in appearance except that circular disks with solid staining centers may greatly outnumber the ring forms. Found on the red blood cells and in the plasma. Size range that of *Eperythrozoon coccoides*, also some larger ring forms.

Cultivation: Not successful.

Immunology: Infection is followed by premunition and latent infection is made manifest by splenectomy. Splenectomized rabbits premunized against *E. coccoides* do not react to inoculation with *E. dispar*; if the latter is injected first, they do not react to *E. coccoides*.

Infectivity: Infective for the European vole (*Arvicola* [*Microtus*] *arvalis*), the American vole (*Microtus pennsylvanicus pennsylvanicus*), the dwarf mouse (*Mus minutus*), the rabbit, and *Mus acomys*. Not infective for albino rats or albino mice.

Source: Blood of infected animals.

Appendix: 1) Species incompletely studied, *Eperythrozoon spp.* and *Eperythrozoon*-like structures (Weinman, Trans. Amer. Philosoph. Soc., N. S. *33*, pt. 3, 1944, 320).

Eperythrozoon noguchii Lwoff and Vaucel. (Bull. Soc. path. exot. *26*, 1933, 397.) Probably not a valid species.

Eperythrozoon perekropovi Yakimoff. (Arch. f. Protistenk., *73*, 1931, 271.) Classification in genus *Eperythrozoon* questionable.

Bartonella wenyoni Nieschulz. (Ztschr. f. Infektionskr., *53*, 1938, 178.) Probably identical with *Eperythrozoon wenyoni*. If valid, *Haemobartonella wenyoni*.

Possible human infection (Schüffner, Nederl. tijdschr. v. geneesk., *73*, 1939, 3778).

2) Animals infected with parasites which are definitely eperythrozoön-like but of uncertain specificity or which are eperythrozoön-like in some features but which can not be definitely classified generically:

Jerboa sp. Kikuth. (Cent. f. Bakt., I Abt., Orig., *123*, 1931, 356.)

Arvicola arvalis Zuelzer. (Zuelzer, Cent. f. Bakt., I Abt., Orig., *102*, 1927, 449; Kikuth, Ergebn. Hyg. Bakt., Immunitätsforsch. u. Exper. therap., *13*, 1932, 559.)

Rattus rattus Schwetz. (Ann. Soc. belge de med. trop., *14*, 1934, 277.)

Sciurus vulgaris Nauck. (Arch. f. Schiffs- u. Trop.-Hyg., *31*, 1927, 322.)

Leptodactylus pentadactylus Carini. (Compt. rend. Soc. Biol., Paris, *103*, 1930, 1312.)

FAMILY III. CHLAMYDOZOACEAE MOSHKOVSKY.*

(Uspekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), *19*, 1945, 12.)

Small, pleomorphic, often coccoid microorganisms usually with characteristic development cycle. Stain with aniline dyes. Gram-negative. Behave as obligate intracytoplasmic parasites. Have not been cultivated in cell-free media. Criteria adequate for classification lacking for more recently isolated members. The attribution of Genus III, *Colesiota*, either to *Rickettsiaceae* or to *Chlamydozoaceae* is still in doubt.

Key to the genera of family **Chlamydozoaceae.**

I. Cells coccoid and with life cycle.
  A. Non-cultivatable in chicken embryonic tissues.
    Genus I. *Chlamydozoon*, p. 1114.
  B. Cultivatable in chicken embryonic tissues.
    Genus II. *Miyagawanella*, p. 1115.
II. Cells pleomorphic.
    Genus III. *Colesiota*, p. 1119.

Genus I. **Chlamydozoon** *Halberstaedter and von Prowazek.*

(Arb. a. d. kaiserl. Gesundheitsamte, *26*, 1907, 44.) From Greek *chlamydos*, cloak and *zoon*, animal.

Coccoid spherical cells with developmental cycle. Gram-negative. Intracytoplasmic habitat. Non-cultivatable in chicken embryonic tissues. Susceptible to sulfonamide and penicillin action.

The type species is *Chlamydozoon trachomatis* Foley and Parrot.

1. **Chlamydozoon trachomatis** Foley and Parrot. (*Rickettsia trachomae* Busacca, Arch. Ophthalm., *52*, 1935, 567; Foley and Parrot, Arch. Inst. Past. d'Algérie, *15*, 1937, 339; *Rickettsia trachomatis* Foley and Parrot, *idem.*) Named for the disease, trachoma.

Coccoid bodies: Small microorganisms 200 to 350 millimicrons in diameter form the elementary bodies. Initial bodies up to 800 millimicrons in diameter and plaques up to 10 microns also found. All larger forms encapsulated with substance derived either from the agent or from the cytoplasm of the parasitized cells. Elementary body is the basic unit. Paired forms or clusters occur. Gram-negative. Stains poorly with aniline dyes; blue or reddish-blue with the Giemsa stain and red or blue, depending on the metabolic state, with the Macchiavello stain. Matrix of plaques gives a strong reaction for glycogen. Non-motile.

Cultivation: Has never been cultivated.

Immunological aspects: Has one or more antigens in common with or closely resembling one or more present in *Miyagawanella spp.* Produces, in low concentrations, antibodies which fix complement with antigen from *Miyagawanella lymphogranulomatis*.

Pathogenicity: Pathogenic for man, apes and monkeys where it affects only

* Prepared by Dr. Geoffrey Rake, The Squibb Institute for Medical Research, New Brunswick, New Jersey, September, 1946.

the cornea and conjunctiva causing highly destructive lesions.

Chemotherapy: Susceptible to sulfonamides and penicillin.

Source: Found in scrapings of cornea or conjunctiva in cases of trachoma.

Habitat: The etiological agent of trachoma in man.

2. **Chlamydozoon oculogenitale** Moshkovsky. (Moshkovsky, Uspekhi Sourемennoi Biologii, *19*, 1945, 12.) From Latin *oculus*, eye and *genitalis*, genital.

Morphology and staining reactions: As for *Chlamydozoon trachomatis*.

Cultivation: Has never been cultivated.

Immunological aspects: As for *C. trachomatis*.

Pathogenicity: Pathogenic for man, baboons and monkeys. Causes an acute conjunctivitis and, in man, an inflammation of the lower genito-urinary tract.

Chemotherapy: Susceptible to sulfonamides and penicillin.

Source: Found in conjunctival exudates, and in exudates from infected urethra or cervix. Also present in contaminated pools of water.

Habitat: The etiological agent of swimming pool conjunctivitis, neonatal conjunctivitis or inclusion conjunctivitis.

Genus II. **Miyagawanella** *Brumpt.*

(Ann. de Parasit., *16*, 1938, 153.) Named for Prof. Miyagawa, the Japanese bacteriologist, who first (1935) grew the type species in the chick embryo.

Coccoid to spherical cells with a developmental cycle. Gram-negative. Intracytoplasmic habitat. Cultivatable in chicken embryonic tissues. Some species are susceptible to sulfonamide or penicillin action.

The type species is *Miyagawanella lymphogranulomatis* Brumpt.

Key to the species of genus **Miyagawanella.**

I. The etiological agent of lymphogranuloma venereum, lymphogranuloma inguinale, climatic bubo, and esthiomène in man.
   1. *Miyagawanella lymphogranulomatis.*

II. The etiological agent of psittacosis or parrot fever.
   2. *Miyagawanella psittaci.*

III. The etiological agent of ornithosis (Meyer).
   3. *Miyagawanella ornithosis.*

IV. The etiological agent of one type of viral pneumonia.
   4. *Miyagawanella pneumoniae.*

V. The etiological agent of mouse pneumonitis (Gönnert).
   5. *Miyagawanella bronchopneumoniae.*

VI. The etiological agent of feline pneumonitis (Baker).
   6. *Miyagawanella felis.*

VII. The etiological agent of Louisiana pneumonia.
   7. *Miyagawanella louisianae.*

VIII. The etiological agent called the Illinois virus, the cause of one type of viral pneumonia.
   8. *Miyagawanella illini.*

1. **Miyagawanella lymphogranulomatis** Brumpt. (Brumpt, Ann. de Parasit., *16*, 1938, 153; *Ehrlichia lymphogranulomatosis* Mauro, (Reference not found.) Named for the disease, lymphogranuloma.

Coccoid bodies: Small microorganisms 200 to 350 millimicrons in diameter form the elementary bodies. Initial bodies up to 1 micron and plaques up to 10 microns also found. All larger forms encapsulated with a substance derived either from the agent or from the cytoplasm of parasitized cells. Elementary body is the basic unit. Paired forms or clusters occur. Gram-negative. Stain with aniline dyes, purple with the Giemsa stain and red or blue, depending on metabolic state, with the Macchiavello stain. Matrix of the plaque does not give the reaction for glycogen. Non-motile.

Filterability: Passes through Chamberland L_2 and L_3, Berkefeld V and N and sometimes through Seitz EK filters.

Cultivation: In plasma tissue cultures of mammalian cells, in mammalian cells on agar, in the chorio-allantoic membrane or particularly in the yolk sac of the chicken embryo but has not been cultivated in the allantoic sac. Optimum temperature 37°C in tissue cultures, 35°C in the chicken embryo.

Immunological aspects: Has one or more antigens in common with or closely resembling one or more present in the chlamydozoa and other miyagawanellae. Antisera against any of these two genera react with antigens from *Miyagawanella lymphogranulomatis* or the other miyagawanellae thus far tested. One common antigen has been isolated as a soluble fraction distinct from the bodies of the agent. Distinguished sharply from the other miyagawanellae by antitoxic neutralization of toxic factor or by neutralization of infections in mice with chicken antisera. Evidence exists that these two serological reactions are with distinct specific antigens. Immunity in man or animals is probably poor in the absence of continuing apparent or inapparent infection.

Toxic factor: Infected yolk sac or yolk injected intravenously or intraperitoneally is rapidly fatal to mice. Produces characteristic lesions on the skin of normal guinea pigs.

Pathogenicity: Pathogenic for man, apes, monkeys, guinea pigs, cotton rats, hamsters, mice, chicken embryos. Inapparent infections may occur with the agent harbored in the organs. Causes local genital lesions, septicemia, lymphadenitis, meningitis, ophthalmitis and rarely pneumonitis in man.

Tissue tropisms: In laboratory rodents this species is infective by the intranasal (pneumonitis), the intracerebral (meningitis) and the intradermal routes.

Chemotherapy: Susceptible to relatively high concentrations of penicillin, to the sulfonamides and to some antimony compounds.

Source: Most commonly the genital secretions of infected individual or the draining lymph nodes. Also occasionally in blood, spinal fluid and ocular secretions.

Habitat: The etiological agent of lymphogranuloma venereum, lymphogranuloma inguinale, climatic bubo, esthiomène and some forms of anorectal inflammation.

2. **Miyagawanella psittaci** (Lillie) Moshkovsky. (*Rickettsia psittaci* Lillie, Publ. Health Repts., *45*, 1930, 773; *Microbacterium multiforme psittacosis* Levinthal,* 1st Cong. internat. de Microbiol., *1*, 1930, 523; Moshkovsky, Uspekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), *19*, 1945, 12; *Ehrlichia psittaci* Moshkovsky, *ibid.*, *19*.) From *Psittaci*, an order of birds.

---

* This is the type species of the genus *Microbacterium* Levinthal which is invalid because of the earlier *Microbacterium* Orla-Jensen, 1919, see p. 370.

Coccoid bodies: As for *Miyagawanella lymphogranulomatis*.

Filterability: Partly filterable through Berkefeld N, Chamberland L and Q or Seitz EK filters.

Cultivation: As for *Miyagawanella lymphogranulomatis* but grows readily in allantoic sac without adaptation.

Immunological aspects: As for *M. lymphogranulomatis* but no soluble fraction yet demonstrated.

Toxic factor: Infected yolk sac or yolk injected intravenously or intraperitoneally is rapidly fatal to mice.

Pathogenicity: Pathogenic for birds (particularly psittacine and finch species), man, monkeys, guinea pigs, pocket gophers, hamsters, white rats, kangaroo rats, mice, rabbits and chicken embryos. Inapparent infections may occur with the agent harbored in the organs. Causes a highly fatal pneumonitis with septicemia in man.

Tissue tropisms: Causes a septicemia. In man this species shows predilection for the respiratory tract. In laboratory rodents, it is infective by the intranasal, the intraperitoneal (peritonitis and septicemia), the intracerebral and the intravenous routes.

Chemotherapy: Susceptible to relatively high concentrations of penicillin. Some strains are susceptible to sulfonamides.

Source: Found in the organs and nasal secretions of infected birds and, from the latter, spreads to the plumage by preening and other methods. Plentiful in droppings or dust from infected cages. Relatively resistant under such conditions.

Habitat: The etiological agent of psittacosis or parrot fever. Also of some cases of atypical pneumonia.

3. Miyagawanella ornithosis Rake, *spec. nov.* From Greek *ornithos*, bird.

Coccoid bodies: As for *Miyagawanella lymphogranulomatis*.

Cultivation: As for *Miyagawanella psittaci*.

Immunological aspects: Has one or more antigens in common with, or closely resembling, one or more present in chlamydozoa and other miyagawanellae as shown by a cross reaction in complement fixation tests. Sharply distinguished from other miyagawanellae by toxin-antitoxin neutralization or by neutralization of infection in mice with chicken antisera. The latter test however suggests that the agent of meningopneumonitis (Francis and Magill, Jour. Exp. Med., *68*, 1938, 147) is this species rather than something distinct. Immunity in man or animals is probably poor except in the presence of continuing apparent or inapparent infections. Cross reactions suggest that *Miyagawanella ornithosis* may be more closely related to *Miyagawanella lymphogranulomatis* than is *M. psittaci*.

Toxic factor: As for *Miyagawanella psittaci*.

Pathogenicity: Pathogenic for birds (especially non-psittacine species), man, ferrets, guinea pigs, hamsters, white rats, kangaroo rats, mice, rabbits and chicken embryos. Inapparent infections may occur. Causes a moderately severe pneumonitis with septicemia in man.

Tissue tropisms: Causes a septicemia. In birds and man shows a predilection for the lungs. In laboratory rodents, this species is infective by the intranasal, intracerebral, intravenous and (with relatively large inocula of most strains) intraperitoneal routes.

Chemotherapy: Susceptible to relatively large doses of penicillin. Not susceptible to sulfonamides.

Source: Found in organs and nasal secretions of finches, pheasants (including domestic chickens), domesticated doves, fulmar petrels and other birds. Spreads from the secretions to plumage and droppings.

Habitat: The etiological agent of ornithosis (Meyer) and meningopneumonitis (Francis and Magill).

4. **Miyagawanella pneumoniae** Rake, *spec. nov.* Named for the disease, pneumonia.

Coccoid bodies: As for *Miyagawanella lymphogranulomatis* but slightly smaller, circa 200 millimicrons in diameter.

Cultivation: As for *Miyagawanella psittaci*.

Immunological aspects: As for *Miyagawanella psittaci*. Distinct from *Miyagawanella ornithosis* by the neutralization test with chicken antisera.

Pathogenicity: Pathogenic for birds, man, cotton rats, hamsters, white rats, kangaroo rats, mice and chicken embryos. Causes a fatal pneumonitis in man.

Tissue tropisms: As for *Miyagawanella ornithosis*.

Chemotherapy: As for *Miyagawanella ornithosis*.

Source: Occurs in lungs of infected humans. Possibly originally of avian origin.

Habitat: The etiological agent of one type of viral pneumonia. The type strain is the so-called strain S-F (Eaton, Beck and Pearson, Journ. Exp. Med., *73*, 1941, 641).

5. **Miyagawanella bronchopneumoniae** Moshkovsky. (Moshkovsky, Uspekhi Souremennoi Biologii, *19*, 1945, 19; *Ehrlichia bronchopneumoniae* Moshkovsky, *idem.*) Named for the disease, bronchopneumonia.

Coccoid bodies: As for *Miyagawanella pneumoniae*.

Cultivation: As for *Miyagawanella lymphogranulomatis*. Does not grow in the allantoic cavity of the chick.

Immunological aspects: As for *Miyagawanella lymphogranulomatis* but no soluble antigen has been demonstrated.

Toxic factor: Heavily infected yolk sacs and yolk injected intravenously are very rapidly fatal to mice.

Pathogenicity: Pathogenic for mice, hamsters and ferrets. Produces a moderately severe pneumonitis.

Tissue tropisms: Shows a predilection for the lungs. In mice, it is also infective by the intravenous route.

Chemotherapy: Susceptible to sulfonamides and to relatively large doses of penicillin.

Source: Found in lungs of certain stocks of the laboratory mouse.

Habitat: The agent of mouse pneumonitis. Bronchopneumonie virus (Gönnert, Cent. f. Bakt., I Abt., Orig., *147*, 1941, 151).

6. **Miyagawanella felis** Rake, *spec. nov.* From Latin *felis*, cat.

Coccoid bodies: As for *Miyagawanella lymphogranulomatis*.

Cultivation: As for *Miyagawanella psittaci*.

Immunological aspects: As for *Miyagawanella psittaci* but nothing known about inapparent infections in the natural host, the domestic cat.

Toxic factor: Infected yolk sac or other membranes and yolk or other fluids, injected intravenously into mice or chicken embryos or intraperitoneally into mice are rapidly fatal.

Pathogenicity: Pathogenic for cats, hamsters, mice and chicken embryos. Causes a fatal pneumonitis with acute conjunctivitis in cats.

Tissue tropisms: Prediliction for lungs and conjunctivae. In laboratory rodents, this species is infective by the intranasal, intraperitoneal, intracerebral and intravenous routes.

Chemotherapy: As for *Miyagawanella ornithosis*.

Source: Lungs of infected cats.

Habitat: The etiological agent of one form of cat nasal catarrh, influenza or distemper (Baker, Science, *96*, 1942, 475) and feline pneumonitis.

7. **Miyagawanella louisianae** Rake, *spec. nov.* Named for the State of Louisiana.

Coccoid bodies: As for *Miyagawanella psittaci*.

Filterability: Filters through Berkefeld N and Mandler 6, 7 and 9 filters.

Cultivation: In the yolk sac of the chicken embryo.

Immunological aspects: Indistinguishable from other miyagawanellae by complement fixation tests with yolk sac antigens. Partly distinguished from *Miyagawanella psittaci* and *M. ornithosis* by active immunization in mice and guinea pigs.

Pathogenicity: Pathogenic for man, guinea pigs, cotton rats, mice and chicken embryos. Slightly pathogenic for white rats, golden hamsters and deer mice. *Macacus rhesus* monkeys, rabbits, muskrats and nutria are unaffected. Causes a highly fatal pneumonitis and septicemia in man.

Tissue tropisms: Causes a septicemia. In man this species shows predilection for the respiratory tract. In laboratory rodents it is infective by the intranasal, intraperitoneal, intracerebral, intramuscular and subcutaneous routes.

Chemotherapy: As for *Miyagawanella ornithosis*.

Source: Sputum and organs of infected persons.

Habitat: The etiological agent of Louisiana pneumonia (Olson and Larson, U. S. Pub. Health Repts., *59*, 1944, 1373), so-called Borg strain.

8. **Miyagawanella illini** Rake, *spec. nov.* Named for the State of Illinois.

Coccoid bodies: As for *Miyagawanella lymphogranulomatis*.

Filterability: Passes through Berkefeld N or W filters.

Cultivation: In the yolk sac of chicken embryo.

Immunological aspects: Distinguished from other miyagawanellae by neutralization tests in mice with chicken antisera and partly from *Miyagawanella psittaci*, *M. ornithosis* and *M. pneumonia* by active immunization in mice.

Pathogenicity: Pathogenic for man and white mice. Causes a highly fatal pneumonitis in man.

Tissue tropisms: Infective in mice by the intranasal, intraperitoneal, intracerebral and subcutaneous routes.

Source: Lungs of infected persons.

Habitat: The etiological agent called the Illinois virus (Zichis and Shaughnessy, Science, *102*, 1945, 301).

Genus III. **Colesiota** Rake, *gen. nov.*

(*Rickettsia* Coles, 17th Rept. Direct. Vet. Serv. and An. Ind. Un. South Africa, 1931, 175.) Named for Prof. Coles who first studied these organisms.

Pleomorphic cells which may be coccoid, triangular, rod-shaped or in the form of rings. Gram-negative. Intracytoplasmic habitat.

The type species is *Colesiota conjunctivae* (Coles) Rake.

1. **Colesiota conjunctivae** (Coles) Rake, *comb. nov.* (*Rickettsia conjunctivae* Coles, 17th Rept. Direct. Vet. Serv. and An. Ind. Un. South Africa, 1931, 175; *Chlamydozoon conjunctivae* Moshkovsky, Uspekhi Souremennoi Biologii, *19*, 1945, 19.) From M. L. *conjunctiva*, the conjunctiva.

Pleomorphic bodies: Average diameter 600 to 950 millimicrons. May be solid and coccoid, rod-shaped, or triangular, or in form of open rings or horse-shoes. No chains. Masses frequent. No capsule. Stains with ordinary aniline dyes but less intensely than bacteria. Gram-negative. Non-motile.

Cultivation: Has never been cultivated.

Immunological aspects: Unknown.

Pathogenicity: Pathogenic for sheep, cattle and goats. Causes acute conjunctivitis and keratitis.

Tissue tropisms: Affects only the conjunctiva and cornea.

Habitat: Found in scrapings of cornea or conjunctiva or in discharges from affected eyes. Etiological agent of infectious or specific ophthalmia in sheep, cattle and goats.

2. **Colesiota conjunctivae-gallii** (Coles) Rake, *comb. nov.* (*Rickettsia conjunctivae-galli* Coles, Onders. Jour. Vet. Sci. and Indust., *14*, 1940, 469.) From conjunctiva and Latin *gallus*, hen.

Pleomorphic bodies: Similar to *Colesiota conjunctivae*. Stain purplish-red or blue with the Giemsa stain.

Cultivation: Has never been cultivated.

Immunological aspects: Unknown.

Pathogenicity: Pathogenic for the domestic fowl. Causes an acute conjunctivitis and keratitis.

Tissue tropisms: As for *Colesiota conjunctivae*.

Source: As for *Colesiota conjunctivae*.

Habitat: The etiological agent of one form of ocular roup in fowls.

Appendix: The following are similar to or identical with the above:

Rickettsia conjunctivae-bovis (Coles, South Afr. Vet. Med. Assoc., 7, 1936, 1) cannot be distinguished from *Colesiota conjunctivae* by any described characteristics.

Rickettsia lestoquardi Donatien and Gayot. (Bull. Soc. Path. Exot., *35*, 1942, 325.) Found in benign conjunctivitis in swine similar to that which occurs in ruminants.

* **Appendix to Order Rickettsiales:** The following are described species of intracytoplasmic and intranuclear parasites of *Protozoa* whose relationships to similar parasites of arthropods and vertebrates are not yet clear. All of the protozoon intracellular parasites are of larger size than typical members of *Rickettsiales* and some have been placed in genera (*Cladothrix*, *Micrococcus*) where the typical species do not live intracellularly.

Genus A. **Caryococcus** *Dangeard.*

(Compt. rend. Acad. Sci., Paris, *134*, 1902, 1365.)

Genus established for a bacterial parasite of the nucleus of *Euglena;* organisms rounded.

The type species is *Caryococcus hypertrophicus* Dangeard.

1. **Caryococcus hypertrophicus** Dangeard. (Compt. rend. Acad. Sci., Paris, *134*, 1902, 1365.) Parasitic in the nucleus of a flagellate (*Euglena deses*).

Occurs in the nucleus as an agglomeration of close-set, rounded corpuscles. The nucleus increases considerably in volume, the chromatin is reduced to thin layers against the membrane, the interior of the nucleus is divided into irregular compartments by chromatic trabeculae.

2. **Caryococcus cretus** Kirby. (Univ. Calif. Publ. Zool., *49*, 1944, 240.) Parasitic in the nucleus of a flagellate (*Trichonympha corbula*) from the intestine of a termite (*Procryptotermes sp.*), Madagascar.

Spherules 1 to 1.5 microns or more in diameter, in preparations appearing clear with usually a chromatic, sharply defined, crescentic structure peripherally or interiorly situated, sometimes with two such bodies or several chromatic granules; parasitic in nucleus; parasitized nucleus enlarged only moderately or not at all, chromatin altered but not greatly diminished in amount.

3. **Caryococcus dilatator** Kirby. (Univ. Calif. Publ. Zool., *49*, 1944, 238.) Parasitic in the nucleus of flagellates (*Trichonympha chattoni* and other species of *Trichonympha*) from the intestine of termites (*Glyptotermes iridipennis*), Australia, and other species.

Spherules 0.5 micron or less in diameter, internally differentiated with stainable granule or stainable region peripherally situated; parasitic in nucleus and nucleolus; nucleus becomes greatly enlarged and the c hromatin mostly or entirely disappears.

4. **Caryococcus invadens** Kirby. (Univ. Calif. Publ. Zool., *49*, 1944, 238.) Parasitic in the nucleus of a flagellate (*Trichonympha peplophora*) from the intestine of a termite (*Neotermes howa*), Madagascar.

Spherules 1 to 1.5 microns in diameter, sometimes arranged in pairs, often internally differentiated with stainable central or peripheral granules or stained areas; parasitic in the nucleolus or endosome and nucleus; parasitized nucleolus becoming greatly enlarged and crossed by trabeculae, eventually consumed; nucleus becoming moderately enlarged, but chromatin not disappearing.

5. **Caryococcus nucleophagus** Kirby. (Univ. Calif. Publ. Zool., *49*, 1944, 236.) Parasitic in the nucleus of a flagellate (*Trichonympha corbula*) from the intestine of termites (*Procryptotermes sp.*), Madagascar, and three species of *Kalotermes* (s. l.) from Madagascar.

---

* **Prepared by Prof. Harold Kirby, Jr., University of California, Berkeley, California, October, 1946.**

Spherules with a diameter of about 0.5 micron, sometimes arranged in pairs, sometimes with a thicker, crescentic, stainable area of the periphery on one side; parasitic within the nucleus, exterior or interior to the chromatin mass, which may be diminished in amount, but does not disappear, nor is the parasitized nucleus appreciably enlarged.

Genus B. **Drepanospira** *Petschenko.*

(Arch. f. Protistenk., *22*, 1911, 282.)

Cell incurved in two spiral turns that are not abrupt, one of the ends pointed, the other a little rounded, no flagella, movement helicoid by means of all the body, no cell division, endospores formed, regular spherical colonies formed by individuals at certain stages of development.

The type species is *Drepanospira mülleri* Petschenko.

1. **Drepanospira mülleri** Petschenko. (*Müllerina paramecii* Petschenko, Cent. f. Bakt., I Abt., Orig., *56*, 1910, 90; Petschenko, Arch. f. Protistenk., *22*, 1911, 252; see also Kirby, in Calkins and Summers, Protozoa in Biological Research, 1941, 1036.) Parasitic in the cytoplasm of *Paramecium caudatum.*

Developing from a group of curved rods in the cytoplasm to a large, ellipsoidal mass almost filling the body. Nuclear portion occupying part of the cell.

The author regards this genus as belonging in the family *Spirillaceae* between *Spirosoma* and *Microspira.*

Genus C. **Holospora** *Haffkine.*

(Ann. Inst. Past., *4*, 1890, 151.)

Genus established for bacterial parasites of the ciliate, *Paramecium aurelia* (= *Paramecium caudatum ?*).

The type species is *Holospora undulata* Haffkine.

1. **Holospora undulata** Haffkine. (Ann. Inst. Past., Paris, *4*, 1890, 151.) In the micronucleus of the ciliate *Paramecium aurelia* (= *P. caudatum?*).

Gradually tapered at ends; 1½, 2 and 2½ spiral turns; develops from a small, fusiform body which grows and divides transversely; brings about a great enlargement of the micronucleus, which becomes filled with the spirals (see *Drepanospira mülleri* Petschenko).

2. **Holospora elegans** Haffkine. (Haffkine, Ann. Inst. Past., Paris, *4*, 1890, 154; see also Kirby, in Calkins and Summers, Protozoa in Biological Research, New York, 1941, 1035.) In the micronucleus of the ciliate, *Paramecium aurelia* (= *P. caudatum ?*).

Vegetative stage fusiform; elongated, elliptical, nucleus-like body in some; divides equatorially, budding at one end; transformation into spore entails enlargement, clear space separating membrane at sides, spore pointed at ends.

3. **Holospora obtusa** Haffkin. (Haffkine, Ann. Inst. Past., Paris, *4*, 1890, 153; also see Fiveiskaja, Arch. f. Protistenk., *65*, 1929, 276.) In the macronucleus of the ciliate *Paramecium aurelia* (= *P. caudatum ?*).

Spores not spiralled and both ends are rounded. Reproduction by fission, also by formation of a bud at one of the extremities of the fusiform cell. Bodies with rounded ends 12 to 30 microns long; also spindle-shaped bodies with pointed

ends, 0.5 by 3 to 6 microns (Fiveiskaja, *loc. cit.*).

The following species have been placed in genera belonging in the orders *Chlamydobacteriales* and *Eubacteriales* respectively:

Cladothrix pelomyxae Veley. (Veley, Jour. Linn. Soc., Zool., *29*, 1905, 375; see also Leiner, Arch. f. Protistenk., *47* 1924, 282; Kirby, in Calkins and Summers, Protozoa in Biological Research, New York, 1941, 1025; Hollande, Bull. Biol. France Belg., *79*, 1945, 49.) In the cytoplasm of the rhizopod, *Pelomyxa palustris* and probably also other species of *Pelomyxa*.

Rods, 1.5 to 22 microns or more in length, divided into several to many sections by transverse partitions, generally aggregated in proximity to the nuclei, which may be thickly invested by close-set bacteria applied to the surface.

Micrococcus batrochorum (*sic*) Yakimoff. (Arch. f. Protistenk., *72*, 1930, 137.) In the cytoplasm of the flagellate, *Trichomonas batrachorum* from the tree toad (*Hyla arborea*). Also seen free in preparations of the intestinal contents of *Hyla*.

Round, 1 to 1.5 microns in diameter, grouped generally in aggregates of irregular form, but also occur individually.

NOTE: Further descriptions of bacterial and other parasites of *Protozoa* with bibliography will be found in Calkins and Summers, Protozoa in Biological Research, New York, 1941, 1009-1113 and in Kirby, Univ. of Calif. Pub. in Zoology, *53* 1946, 193-207.

SUPPLEMENT NO. 2

ORDER VIRALES
THE FILTERABLE VIRUSES

FILTERABLE VIRUSES*

The so-called filterable viruses, today generally called merely viruses, are still of unknown affiliations so far as relationships to established groups of microorganisms are concerned. They are treated here as members of an order, consisting of 13 families, 32 genera and 248 species.

Among viruses as we know them, there are three constituent groups that have come to be recognized, and to some extent named and classified, through the largely separate efforts of bacteriologists, animal pathologists, and plant pathologists. Taxonomic overlapping of the three groups, viruses affecting bacteria, viruses having only animal hosts, and viruses invading higher plants, can hardly be justified as yet by available evidence. Nevertheless it has been shown that a single virus may multiply both in a plant host and in an insect vector. This seems to dispose of the thought that adaptation to a plant or animal environment would necessarily preclude utilization of other sources of the materials needed for multiplication.

For the present it seems feasible to continue with the custom, tacitly accepted in the past, of classifying bacteriophages separately as one sub-group, viruses causing diseases in seed plants as a second sub-group, and those causing diseases in animals as a third sub-group. It should be recognized that this may prove to be only a temporary arrangement, necessary because we have no evidence to warrant taxonomic overlapping of the three groups and useful while we await critical investigations and possible development of a substitute plan capable of displaying natural relationships to better advantage. Eventually evidence may become available to show that some bacteriophages can infect higher plants or animals and can increase in the new environment, or that viruses known to attack animals or plants can similarly enlarge their host ranges. Or, there may be discoveries of common physical properties that would aid in formulating an interlocking classification, for which at present we lack any substantial basis.

It is of especial significance now that the three fields be unified at least by a parallel development of nomenclature. Toward this end the present section of this supplement is directed.

*** Supplement No. 2 has been prepared by Francis O. Holmes, The Rockefeller Institute for Medical Research, Princeton, N. J., September, 1944. In this section, authorities for the names of plant hosts are in general as given by Gray's New Manual of Botany, 7th edition, and Bailey's Manual of Cultivated Plants, 1938; in each of these standard works will be found a list of abbreviations customarily used in botany in citing authorities for binomials.**

ORDER VIRALES Breed, Murray and Hitchens.

(Jour. Bact., *47*, 1944, 421.)

Viruses. Etiological agents of disease, typically of small size and capable of passing filters that retain bacteria, increasing only in the presence of living cells, giving rise to new strains by mutation, not arising *de novo*. A considerable number of viruses have not been proved filterable; it is nevertheless customary to include these viruses with those known to be filterable, because of similarities in other attributes and in the diseases induced. Some not known to be filterable are inoculable only by special techniques, as by grafting or by use of insect vectors, and suitable methods for testing their filterability have not been developed; moreover, it is not certain that so simple a criterion as size measured in terms of filterability will prove to be an adequate indicator of the limits of the natural group. Cause diseases of bacteria, plants and animals.

Key to the suborders of order **Virales.**

I. Infecting bacteria.
  Suborder I. *Phagineae*, p. 1128.
II. Infecting higher plants.
  Suborder II. *Phytophagineae* p. 1145.
III. Infecting animals (insects, mammals).
  Suborder III. *Zoophagineae*, p. 1225.

SUBORDER I. **Phagineae** *subordo novus.*

Viruses pathogenic in bacteria; bacteriophages. Containing at present only one family, the *Phagaceae*.

FAMILY I. PHAGACEAE HOLMES.

(Handb. Phytopath. Viruses,* 1939, 1.)

Characters those of the suborder. There is a single genus.

Genus I. **Phagus** *Holmes.*

(*Loc. cit.*, 1.)

Characters those of the family. Generic name from Greek *phagein*, to eat.

The type species is *Phagus minimus* Holmes.

NOTE: *Bacteriophagum* d'Herelle (Compt. rend. Soc. Biol., Paris, *81*, 1918, 1161) a genus name applied in connection with early studies of bacteriophages, had as its type species *Bacteriophagum intestinale* d'Herelle, a bacteriophage that is not now identifiable or, more probably, a mixture of such unidentifiable bacteriophages, for filtrates containing it were said to be capable of killing outright a culture of bacteria (*ibid.*, 1160). The genus name *Bacteriophagum* is, therefore, regarded as a *nomen dubium*, if not also a *nomen confusum;* subsequently it was abandoned by its author, for reasons that are not clear, in favor of the genus name *Protobios* d'Herelle 1924 (Immunity in natural infectious disease; page 343 of authorized English edition by George H. Smith, Baltimore, Williams & Wilkins Co., 1924, 399 pp). *Protobios protobios*

* Holmes, F. O., Handbook of Phytopathogenic Viruses, Burgess Publishing Company, Minneapolis, Minn., 1939, 221 pp.

d'Herelle (*loc. cit.*, 345), presumably the type species of this genus, was not an ordinary virus but was said to be non-parasitic (i.e., free-living) in nature, was capable of reducing sulphur, and is not now identifiable. The genus name *Protobios* and the corresponding binomial *Protobios bacteriophagus* d'Herelle are therefore regarded also as *nomina dubia* and are not used here. *Bacteriophagus* Thornberry (Phytopath., *31*, 1941, 23) appears to represent a variant spelling of d'Herelle's earlier genus name; it was not accompanied by any indication of what recognizable single bacteriophage served as type and thus does not modify the standing of *Bacteriophagum*.

Key to the species of genus **Phagus.**

I. Dysentery-coli bacteriophages.

A. Producing large plaques, 8 to 12 mm in diameter.

1. Particle size small, 8 to 12 millimicrons.

1. *Phagus minimus.*

2. Particle size 15 to 20 millimicrons.

2. *Phagus minor.*

B. Producing moderately large plaques, 2 to 6 mm in diameter, with distinct halo.

1. Particle size 20 to 30 millimicrons.

3. *Phagus parvus.*
4. *Phagus primarius.*
5. *Phagus secundarius.*
6. *Phagus dysenteriae.*

C. Plaques medium size, 1 to 3 mm in diameter, with distinct halo.

1. Particle size 25 to 40 millimicrons.

7. *Phagus medius.*
8. *Phagus astrictus.*

D. Plaques small, 0.5 to 1.5 mm in diameter, with soft edge or narrow halo.

1. Particle size 30 to 45 millimicrons.

9. *Phagus major.*
10. *Phagus coli.*
11. *Phagus artus.*

E. Plaques very small, 0.1 to 1.2 mm in diameter, with sharp edges.

1. Particle size 50 to 75 millimicrons.

12. *Phagus maximus.*

II. Bacteriophages attacking *Agrobacterium tumefaciens* Conn, *Pseudomonas solanacearum* Smith, *Xanthomonas citri* Dowson, *Xanthomonas pruni* Dowson, *Erwinia carotovora* Holland, *Erwinia aroideae* Holland, *Bacterium stewarti* E. F. Smith.

A. Specific for bacterial hosts named above.

13. *Phagus tumoris.*
14. *Phagus solanacearum.*
15. *Phagus citri.*
16. *Phagus pruni.*
17. *Phagus deformans.*
18. *Phagus contumax.*
19. *Phagus maidis.*

III. Bacteriophages attacking *Salmonella enteritidis* Castellani and Chalmers.

20. *Phagus enteritidis.*
21. *Phagus commutabilis.*
22. *Phagus tertius.*
23. *Phagus dubius.*

IV. Bacteriophage attacking *Salmonella typhosa.*

24. *Phagus indicens.*

V. Bacteriophages attacking *Bacillus megatherium* DeBary, *Bacillus mycoides* Flügge, and *Rhizobium leguminosarum* Frank.

A. Thermal inactivation at 75° C in 10 minutes *in vitro.*

1. Host may be freed from bacteriophage by heating at 80° C for 10 minutes.

25. *Phagus testabilis.*

2. Host retains virus even when heated at 90° C for 10 minutes.

26. *Phagus indomitus.*

B. Thermal inactivation at 60° C in 30 minutes.

27. *Phagus subvertens.*

VI. Bacteriophages attacking streptococci.

28. *Phagus ineptus.*
29. *Phagus streptococci.*
30. *Phagus maculans.*
31. *Phagus lacerans.*
32. *Phagus tolerans.*
33. *Phagus michiganensis.*

VII. Bacteriophages attacking staphylococci.

34. *Phagus fragilis.*
35. *Phagus intermedius.*
36. *Phagus caducus.*
37. *Phagus alpha.*
38. *Phagus beta.*

39. *Phagus durabilis.*
40. *Phagus liber.*

VIII. Bacteriophages attacking vibrios.

41. *Phagus cholerae.*
42. *Phagus celer.*
43. *Phagus effrenus.*
44. *Phagus lentus.*

IX. Bacteriophages attacking *Corynebacterium diphtheriae* Lehmann and Neumann.

45. *Phagus diphtheriae.*
46. *Phagus futilis.*

1. **Phagus minimus** Holmes. (Handb. Phytopath. Viruses, 1939, 141.) From Latin *minimus*, least, in reference to size.

Common name: Bacteriophage S13.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: On plate cultures that are uniformly covered with confluent colonies of host organisms, this bacteriophage produces large cleared plaques, 8 to 12 mm in diameter, with wide shelving edges.

Serological relationships: No cross-neutralization reactions with bacteriophages C13, C36, D5, D20, C18, D3, S8, C21, C16, and D6.

Immunological relationships: Member of Resistance Group I.

Other properties: Particle size 8 to 12 millimicrons. Not affected by 26.3 per cent urea solution. Little or no inactivation by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes. Lysis completely inhibited by 0.25 per cent solution of sodium citrate.

Literature: Burnet and McKie, Jour. Path. and Bact., *36*, 1933, 299–306, 307–318; *37*, 1933, 179–184; Burnet et al., Austral. Jour. Exp. Biol. and Med. Sci., *15*, 1937, 227–368.

2. **Phagus minor** H. (*loc. cit.*, 141). From Latin *minor*, lesser.

Common names: Bacteriophage C13, C8, and D44.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: Large plaques, 8 to 12 mm in diameter, with wide shelving edges.

Serological relationships: Cross reactions with bacteriophages C8 and D44 but not with bacteriophages S13, C36, D5, D20, D13, C18, D3, S8, C21, C16, D6.

Immunological relationships: Member of Resistance Group I.

Other properties: Particle size, 15 to 20 millimicrons. Completely inactivated by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes. Specific soluble substance formed in lysed cultures blocks phage-antiphage reaction.

Literature: Burnet, Jour. Path. and Bact., *36*, 1933, 307–318; Brit. Jour. Exp. Path., *14*, 1933, 100–108.

3. **Phagus parvus** H. (*loc. cit.*, 142). From Latin *parvus*, small.

Common names: Bacteriophage C36, S18, C38, M, and C37 of Burnet.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: Moderately large plaques, 2 to 6 mm in diameter, with distinct halo.

Serological relationships: Induces formation of antibody capable of neutralizing bacteriophages S18, C38, M, and C37, but not bacteriophages S13, C13, D5, D20, D13, C18, D3, S8, C21, C16, or D6, which represent distinct serological groups.

Immunological relationships: Member of Resistance Group I.

Other properties: Particle size, 20 to 30 millimicrons. Completely inactivated by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes.

Literature: Burnet, Jour. Path. and Bact., *36*, 1933, 307–318.

4. **Phagus primarius** H. (*loc. cit.*, 143). From Latin *primarius*, chief or first.

Common names: Bacteriophage D5, C51, C50, and D48.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: Moderately large plaques, 2 to 6 mm in diameter, with distinct halos.

Serological relationships: Cross-neutralization reactions with bacteriophages C51, C50, and D48, but not with S13, C13, C36, D20, D13, C18, D3, S8, C21, C16, D6.

Immunological relationships: Member of Resistance Group I.

Other properties: Particle size, 20 to 30 millimicrons. Completely inactivated by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes.

Literature: Burnet, Jour. Path. and Bact., *36*, 1933, 307–318.

5. **Phagus secundarius** H. (*loc. cit.*, 143). From Latin *secundarius*, inferior or second.

Common names: Bacteriophage D20 and G.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: Moderately large plaques, 2 to 6 mm in diameter, with distinct halo.

Serological relationships: No cross-neutralization reactions with bacteriophages S13, C13, C36, D5, D13, C18, D3, S8, C21, C16, or D6.

Immunological relationships: Member of Resistance Group II.

Other properties: Nearly all inactivated by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes. Particle size, 20 to 30 millimicrons.

Literature: Burnet, Jour. Path. and Bact., *36*, 1933, 307–318.

6. **Phagus dysenteriae** H. (*loc. cit.*, 144). From Latin *dysenteria*, dysentery.

Common names: Bacteriophage D13, specific dysentery phage.

Host: *Shigella dysenteriae* Castellani and Chalmers.

Insusceptible species: *Escherichia coli* Castellani and Chalmers.

Induced disease: Moderately large plaques, 2 to 6 mm in diameter, with distinct halo.

Serological relationships: Antiserum to this strain is not known to be effective against any other strain of bacteriophage; in particular, no cross reactions with bacteriophages S13, C13, C36, D5, D20, C18, D3, S8, C21, C16, or D6.

Immunological relationships: Member of Specific Dysentery Resistance Group.

Other properties: Particle size, 20 to 30 millimicrons. Completely inactivated by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes.

Literature: Burnet, Jour. Path. and Bact., *36*, 1933, 307–318.

7. **Phagus medius** H. (*loc. cit.*, 144). From Latin *medius*, moderate, in reference to particle size.

Common name: Bacteriophage C18, C35, C26, C47, or C34.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: Medium size plaques, 1 to 3 mm in diameter, with distinct halo.

Serological relationships: Cross reactions with bacteriophages C35, C26, C47, and C34, but not with S13, C13, C36, D5, D20, D13, D3, S8, C21, C16, or D6.

Immunological relationships: Member of Resistance Group II.

Other properties: Particle size, 25 to 40 millimicrons.

Literature: Burnet, Jour. Path. and Bact., *36*, 1933, 307–318.

8. **Phagus astrictus** H. (*loc. cit.*, 145). From Latin *astrictus*, limited, in reference to inability to lyse *Escherichia coli* Castellani and Chalmers.

Common names: Bacteriophage D3; "smooth" dysentery phage.

Host: *Shigella dysenteriae* Castellani and Chalmers.

Insusceptible species: *Escherichia coli* Castellani and Chalmers.

Induced disease: Medium size plaques, 1 to 3 mm in diameter, with distinct halo.

Serological relationships: No cross-neutralization reactions with bacteriophages S13, C13, C36, D5, D20, D13, C18, S8, C21, C16, or D6.

Immunological relationships: Member of Smooth Dysentery Resistance Group.

Other properties: Particle size, 25 to 40 millimicrons. Nearly all inactivated by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes.

Literature: Burnet, Jour. Path. and Bact., *36*, 1933, 307–318.

9. **Phagus major** H. (*loc. cit.*, 146). From Latin *major*, greater, in reference to particle size.

Common name: Bacteriophage S8, L, S28, C33, or S41.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: Small plaques, 0.5 to 1.5 mm in diameter, with soft edge or narrow halo.

Serological relationships: No cross-neutralization reactions with bacteriophages S13, C13, C36, D5, D20, D13, C18, D3, C21, C16, or D6.

Immunological relationships: Member of Resistance Group I.

Other properties: Particle size, 30 to 45 millimicrons.

Literature: Burnet, Jour. Path. and Bact., *36*, 1933, 307–318; Brit. Jour. Exp. Path., *14*, 1933, 100–108; Gough and Burnet, *ibid.*, *38*, 1934, 301–311.

10. **Phagus coli** H. (*loc. cit.*, 146). From Latin *colon*, the colon.

Common names: Bacteriophage C21 or C5; specific *coli* phage.

Host: *Escherichia coli* Castellani and Chalmers.

Insusceptible species: *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: Small plaques, 0.5 to 1.5 mm in diameter, with soft edge or very narrow halo.

Serological relationships: No cross-neutralization with bacteriophages S13, C13, C36, D5, D20, D13, C18, D3, S8, C16, or D6.

Immunological relationships: Member of Specific *Escherichia coli* Resistance Group.

Other properties: Particle size, 30 to 45 millimicrons. Completely inactivated by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes.

Literature: Burnet, Jour. Path. and Bact., *36*, 1933, 307–318.

11. **Phagus artus** H. (*loc. cit.*, 148). From Latin *artus*, narrow, in reference to limited host range.

Common names: Bacteriophage D6, D33; smooth dysentery phage.

Host: *Shigella dysenteriae* Castellani and Chalmers, smooth strains.

Induced disease: Small plaques, 0.5 to 1.5 mm in diameter, with soft edge or very narrow halo.

Serological relationships: Not neu-

tralized by sera specific for bacteriophages S13, C13, C36, D5, D20, D13, C18, D3, S8, C21, or C16.

Immunological relationships: Member of Smooth Dysentery Resistance Group.

Other properties: Particle size, 30 to 45 millimicrons.

Literature: Burnet, Jour. Path. and Bact., *36*, 1933, 307–318.

12. **Phagus maximus** H. (*loc. cit.*, 147). From Latin *maximus*, greatest, in reference to particle size.

Common names: Bacteriophage C16, C4, C15, C20, C32, C46, D4, D12, D29, D53, H, J, K, and W. L. L.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: Small plaques, 0.1 to 1.2 mm in diameter, with sharp edges.

Serological relationships: No cross-neutralization reaction with bacteriophages S13, C13, C36, D5, D20, D13, C18, D3, S8, C21, D6, or staphylococcus bacteriophage Au2. Agglutinated and inactivated by homologous, though not by other, antisera. For agglutination an original titer of 2×10^9 or higher is required; the reaction is visible to the unaided eye after 24 hours at 50° C and succeeds even after inactivation by heat (70 to 85° C for 30 minutes), formaldehyde, or a photodynamic dye (proflavine).

Immunological relationships: Member of Resistance Group II.

Thermal inactivation: At or below 70° to 85° C for 30 minutes.

Other properties: Particle size estimated by filtration as 50 to 75 millimicrons, by centrifuging as 79 to 90 millimicrons, from photographs as 50 to 60 millimicrons. Rapidly inactivated by 26.3 per cent urea solution. Little or no inactivation by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes. Lysis not inhibited by 1.5 per cent or weaker solutions of sodium citrate. Thermolabile specific soluble substance formed in lysed cultures blocks phage-antiphage reaction.

Literature: Burnet, Brit. Jour. Exp. Path., *14*, 1933, 93–100, 100–108, 302–308; Jour. Path. and Bact., *36*, 1933, 307–318; *37*, 1933, 179–184; Burnet and Lush, *ibid.*, *40*, 1935, 455–469; Burnet and McKie, *ibid.*, *36*, 1933, 299–306.

13. **Phagus tumoris** H. (*loc. cit.*, 150). From Latin *tumor*, a swelling, in reference to association of this bacteriophage with bacterial tumors.

Common name: *Agrobacterium tumefaciens* bacteriophage.

Host: *Agrobacterium tumefaciens* Conn, most strains.

Insusceptible species: Some strains of *Agrobacterium tumefaciens*, *Bacterium stewarti* E. F. Smith, *Erwinia atroseptica* Bergey et al., *E. carotovora* Holland, *Pseudomonas tabaci* Stapp, *Xanthomonas beticola* Burkholder, *X. campestris* Dowson, *X. citri* Dowson, *X. phaseoli* Dowson *X. pruni* Dowson and *X. vesicatoria* Dowson.

Geographical distribution: United States, Russia.

Induced disease: Plaques 2 to 6 mm in diameter in 4 to 6 hours, edges of plaques spotted, moth-eaten in appearance until 40 hours after seeding; enlargement then stops and the edges of the plaques become smooth, double-ringed. Infection of plants by *Agrobacterium tumefaciens* is progressively inhibited by increasing amounts of bacteriophage in inoculum.

Thermal inactivation: At 95° C in 10 minutes (another report says 70° C, time not recorded).

Other properties: Resists dilution to $1:10^{11}$; storage at 5° C for over 25 months; prompt, though not gradual, drying; 1 per cent hydrogen peroxide for 72 hours; 95 per cent ethyl alcohol for 1 hour; 70 per cent ethyl alcohol for 6 hours; 2½ per cent phenol for 1 hour; 1:3000 nitric acid for 1 hour; N/64 sodium hydroxide for 1 hour.

Literature: Israilsky, Cent. f. Bakt.,

II Abt., *67*, 1926, 236–242; *71*, 1927, 302–311; *79*, 1929, 354–370; Kent, Phytopath., *27*, 1937, 871–902; Muncie and Patel, Phytopath., *20*, 1930, 289–305.

14. **Phagus solanacearum** H. (*loc. cit.*, 148). From name of host.

Common name: *Pseudomonas solanacearum* bacteriophage.

Host: *Pseudomonas solanacearum* Smith.

Geographical distribution: Formosa (Taiwan).

Induced disease: Medium size plaques on plate cultures of *Pseudomonas solanacearum.*

Serological relationships: When injected into rabbits, this bacteriophage stimulates the production of a specific precipitating antibody not giving cross reactions with anti-bacterial antibodies. Antiphagic serum inactivated at 90° C in 10 minutes.

Thermal inactivation: At 63° C in 10 minutes (61° C in 30 minutes; 66° C in about 1 minute).

Other properties: Optimum temperature for increase, 34° C.

Literature: Matsumoto and Okabe, Jour. Plant Prot., *22*, 1935, 15–20; Jour. Soc. Trop. Agr., *7*, 1935, 130–139; *9*, 1937, 205–213.

15. **Phagus citri** H. (*loc. cit.*, 149). From name of host.

Common name: *Xanthomonas citri* bacteriophage.

Host: *Xanthomonas citri* Dowson, the citrus canker organism.

Geographical distribution: Formosa (Taiwan).

Induced disease: Lysis. This bacteriophage has been isolated from soil under diseased trees, and once from infected leaves. It may play a role in the destruction of the citrus canker organism in the soil.

Other properties: Optimum temperature for increase, 30° C.

Literature: Matsumoto and Okabe, Agriculture and Horticulture, *12*, 1937, 2055–2059.

16. **Phagus pruni** H. (*loc. cit.*, 151). From name of host.

Common name: *Xanthomonas pruni* bacteriophage.

Host: *Xanthomonas pruni* Dowson.

Geographical distribution: United States (from soil beneath infected peach trees).

Induced disease: Lysis in broth cultures; plaques on agar cultures, but characteristics of plaques not described.

Other properties: Estimated diameter 11 millimicrons in broth. Resists dilution to $1:10^6$ or more.

Literature: Anderson, Phytopath., *18*, 1928, 144; Thornberry, *ibid.*, *25*, 1935, 938–946.

17. **Phagus deformans** H. (*loc. cit.*, 151). From Latin *deformare*, to disfigure, in reference to malformation of infected host cells.

Common name: *Erwinia carotovora* bacteriophage.

Host: *Erwinia carotovora* Holland.

Insusceptible species: *Agrobacterium tumefaciens* Conn, except in some early tests with possibly mixed bacteriophages; *Erwinia amylovora* Winslow et al., *E. melonis* Holland, *Salmonella pullorum* Bergery et al., *S. gallinarum* Bergey et al., Shigella dysenteriae Castellani and Chalmers, *Xanthomonas pruni* Dowson.

Geographical distribution: United States (Michigan).

Induced disease: In *Erwinia carotovora*, cells reduced in motility, agglutinated, malformed, some elongated, others swollen, bulged at one end, bulged in middle, or enlarged and spherical.

Other properties: Resists dilution to $1:10^9$, and storage in sterile medium at room temperature for 5½ months.

Literature: Coons and Kotila, Phytopath., *15*, 1925, 357–370; Mallmann and Hemstreet, Jour. Agr. Res., *28*, 1924, 599–602.

18. **Phagus contumax** *spec. nov.* From Latin *contumax*, refractory, in reference to ability of this bacteriophage to withstand heating sufficient to destroy accompanying host cells.

Common name: *Erwinia aroideae* bacteriophage.

Host: *Erwinia aroideae* Holland.

Insusceptible species: *Agrobacterium tumefaciens* Conn, *Bacterium formosanum* Okabe, *Erwinia carotovora* Holland, *Pseudomonas andropogoni* Stapp, *P. solanacearum* Smith, *P. tomato* Burkholder, *Xanthomonas campestris* Dowson, *X. citri* Dowson, *X. malvacearum* Dowson, *X. nakatae* Dowson, *X. phaseoli* Dowson, *X. ricinicola* Dowson.

Geographical distribution: Formosa (Taiwan).

Induced disease: Very small plaques, 0.1 to 1.0 mm (mostly less than 0.5 mm) in diameter.

Thermal inactivation: Resists heating at 60° C for 30 minutes without appreciable loss of titer, but host organism is killed by this treatment.

Other properties: Optimum temperature for increase, about 25° C. This bacteriophage may be prepared by heating centrifuged cultures at 60° C for 30 minutes as efficiently as by filtration to remove bacteria.

Literature: Matsumoto, Trans. Nat. Hist. Soc. Formosa, *29*, 1939, 317–338; *30*, 1940, 89–98; *31*, 1941, 145–154; Matsumoto and Sawada, *ibid.*, *28*, 1938, 247–256.

19. **Phagus maidis** H. (*loc. cit.*, 152). From New Latin *mais*, corn (maize), host of *Bacterium stewarti*.

Common name: *Bacterium stewarti* bacteriophage; *Phytomonas stewarti* bacteriophage; *Aplanobacter stewarti* bacteriophage.

Host: *Bacterium stewarti* E. F. Smith (= *Pseudomonas stewarti* E. F. Smith, *Phytomonas stewarti* Bergey et al. and *Aplanobacter stewarti* McCulloch).

Geographical distribution: United States.

Induced disease: In *Bacterium stewarti*, variation or loss of yellow color, change of viscosity of growth, reduction or loss of virulence. Infection of corn plants by seed-borne *Bacterium stewarti* is much reduced by treating seeds with this bacteriophage before they are planted.

Thermal inactivation: Above 65° C in 30 minutes.

Other properties: Infective in dilutions to 10^{-7}. Soon lost from cultures maintained at pH 3.85 to 4.00, or on Ivanoff's medium, which contains oxidizing compounds.

Literature: Thomas, Phytopath., *25*, 1935, 371–372; Science, *88*, 1938, 56–57; Phytopath., *30*, 1940, 602–611.

20. **Phagus enteritidis** H. (*loc. cit.*, 153). From name of host.

Common names: *Salmonella enteritidis* bacteriophage 1, 12, or 33; Group A bacteriophages.

Hosts: *Salmonella enteritidis* Castellani and Chalmers, *S. gallinarum* Bergey et al., *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: Plaques of medium size, usually with surrounding translucent halo.

Immunological relationships: Member of Resistance Group A; host individuals that have acquired resistance to this bacteriophage are resistant to lines 12 and 33, but susceptible to *Salmonella enteritidis* bacteriophages 8, 20, and 11, as well as to other strains of Resistance Groups B, C, and D.

Literature: Burnet, Jour. Path. and Bact., *32*, 1929, 15–42.

21. **Phagus commutabilis** H. (*loc. cit.*, 153). From Latin *commutabilis*, variable, in reference to differences within Resistance Group B, typified by this bacteriophage.

Common names: *Salmonella enteritidis* bacteriophage 8, 18, 28, 31, 34, 38; Group B bacteriophages.

Hosts: *Salmonella enteritidis* Castellani

and Chalmers, *Shigella dysenteriae* Castellani and Chalmers, *Shigella gallinarum* Weldin, *Salmonella typhosa* White.

Induced disease: Small plaques with sharp edges, or moderately large plaques with characteristic halo.

Immunological relationships: Member of Resistance Group B; host individuals that have acquired resistance to this bacteriophage are resistant to lines 18, 28, 31, 34, and 38, but susceptible to *Salmonella enteritidis* bacteriophages 1, 20, and 11, as well as to other strains of Resistance Groups A, C, and D.

Literature: Burnet, Jour. Path. and Bact., *32*, 1929, 15–42.

22. **Phagus tertius** H. (*loc. cit.*, 154). From Latin *tertius*, third, in reference to the third Resistance Group of *Salmonella enteritidis* bacteriophages, Group C, typified by this bacteriophage.

Common names: *Salmonella enteritidis* bacteriophage 20, 25, 32, 35; Group C bacteriophages.

Hosts: *Salmonella enteritidis* Castellani and Chalmers, *S. gallinarum* Bergey et al., *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: Plaques of small size, with sharp edges.

Immunological relationships: Member of Resistance Group C. Host individuals that have acquired resistance to this bacteriophage are resistant to lines 25, 35, and 32, but susceptible to *Salmonella enteritidis* bacteriophages of Resistance Groups A, B, and D.

Literature: Burnet, Jour. Path. and Bact., *32*, 1929, 15–42.

23. **Phagus dubius** H. (*loc. cit.*, 155). From Latin *dubius*, doubtful, in reference to uncertainty of distinction between Resistance Groups C and D.

Common names: *Salmonella enteritidis* bacteriophage 11, 13; Group D bacteriophages.

Hosts: *Salmonella enteritidis* Castellani and Chalmers, *Shigella dysenteriae* Castellani and Chalmers, *Shigella gallinarum* Weldin.

Induced disease: Very large plaques, up to 8 mm in diameter on 1.2 per cent agar.

Immunological relationships: Member of Resistance Group D. Host individuals that have acquired resistance to this bacteriophage are resistant to line 13, but susceptible to *Salmonella enteritidis* bacteriophages of Resistance Groups A, B, and C.

Literature: Burnet, Jour. Path. and Bact., *32*, 1929, 15–42.

24. **Phagus indicens** *spec. nov.* From Latin *indicere*, to disclose or indicate, in reference to diagnostic use of this bacteriophage in identifying V forms of the typhoid bacillus.

Common name: Phage Q151.

Host: *Salmonella typhosa* White (= *Bacillus typhosus* Zopf).

Insusceptible species: W forms of the typhoid organism and various *Salmonella* species.

Geographical distribution: Canada.

Induced disease: In *Salmonella typhosa*, small plaque formation (lysis) and complete inhibition of growth in cultures of the V form (bearing Vi antigen; resisting O agglutination) and no lysis or restraining effect on growth of the W form (lacking Vi antigen; agglutinated by O antiserum). In the presence of the virus, mixed cultures are quickly transformed since only W variants can increase. Pure V cultures can be identified by the test for their complete inhibition; this inhibition is regularly followed by secondary growth representing the pure W form of the host, a readily formed variant.

Filterability: Passes Seitz EK filter.

Other properties: Filtrates active in dilutions to 10^{-9} or 10^{-11}.

Literature: Craigie, Jour. Bact., *31*, 1936, 56 (Abst.); Craigie and Brandon, Jour. Path. and Bact., *43*, 1936, 233–248, 249–260.

25. **Phagus testabilis** H. (*loc. cit.*, 155). From Latin *testabilis*, able to bear witness, in reference to evidence that this bacteriophage has given, by virtue of its easy destruction when heated in spores, against the hypothesis of frequent spontaneous origin of bacteriophage from the bacterial host.

Common name: *Bacillus megatherium* bacteriophage.

Host: *Bacillus megatherium* De Bary.

Geographical distribution: United States.

Induced disease: Plaques 0.5 mm or less in diameter, with surrounding translucent zone.

Thermal inactivation: *In vitro*, at 75° C in 10 minutes. Spores from infected cultures, after being heated for 10 minutes at 80° C, regularly give rise to subcultures that do not show the presence of this bacteriophage spontaneously during subsequent growth but that are susceptible to lysis if the bacteriophage is again introduced.

Literature: Adant, Compt. rend. Soc. Biol., Paris, *99*, 1928, 1246; Cowles, Jour. Bact., *20*, 1930, 15–23.

26. **Phagus indomitus** H. (*loc. cit.*, 156). From Latin *indomitus*, unrestrained, in reference to the ability of this bacteriophage to increase after heat treatment of infected spores.

Common name: *Bacillus mycoides* bacteriophage.

Host: *Bacillus mycoides* Flügge, some strains.

Insusceptible species: *Bacillus cereus* Frankland and Frankland, *B. subtilis* Cohn emend. Prazmowski, *B. megatherium* De Bary, *B. anthracis* Cohn emend. Koch. Some strains of *B. mycoides*.

Geographical distribution. United States.

Induced disease: Large plaques, with some secondary growth of host organism.

Thermal inactivation: *In vitro*, at 75° C in 10 minutes. Spores from infected cultures, heated at 90° C for 10 minutes give no bacteriophage on grinding, but lytic cultures when grown.

Literature: Lewis and Worley, Jour. Bact., *32*, 1936, 195–198.

27. **Phagus subvertens** H. (*loc. cit.*, 156). From Latin *subvertere*, to subvert, in reference to suspected action of this bacteriophage in causing running-out of alfalfa fields through destruction of nodule organisms.

Common name: *Rhizobium leguminosarum* bacteriophage.

Host: *Rhizobium leguminosarum* Frank. It has been shown that this bacteriophage is unable to increase in clover roots without the nodule-forming organism, *R. leguminosarum*, and that the bacteriophage plays no obviously essential role in nodule formation.

Induced disease: Very small plaques, with edges not sharply defined.

Thermal inactivation: At 60° C in 30 minutes.

Other properties: Not inactivated by drying for 2 months.

Literature: Gerretsen et al., Cent. f. Bakt., II Abt., *60*, 1923, 311–316; Grijns, *ibid.*, *71*, 1927, 248–251; Hitchner, Jour. Bact., *19*, 1930, 191–201; Vandecaveye and Katznelson, Jour. Bact., *31*, 1936, 465–477.

28. **Phagus ineptus** H. (*loc. cit.*, 157). From Latin *ineptus*, unsuitable, in reference to inability of this bacteriophage to adapt itself to lysis of strain RW of its host.

Common name: Streptococcus bacteriophage R.

Host: *Streptococcus cremoris* Orla-Jensen, strain R.

Insusceptible species: *Streptococcus cremoris*, strain RW.

Geographical distribution: New Zealand.

Induced disease: Plaques 0.25 to 0.6 mm in diameter.

Serological relationships: Antisera specific for streptococcus bacteriophage RW

and its strain RW1 are ineffective in neutralizing this bacteriophage.

Immunological relationships: Cultures of host-strain R, after exposure to this bacteriophage, furnish subcultures only partly resistant to this bacteriophage and completely susceptible to streptococcus bacteriophage RW and its substrain RW1.

Literature: Whitehead and Hunter, Jour. Path. and Bact., *44*, 1937, 337–347.

29. **Phagus streptococci** H. (*loc. cit.*, 158). From generic name of host.

Common name: Streptococcus bacteriophage RW.

Host: *Streptococcus cremoris* Orla-Jensen, strain RW.

Geographical distribution: New Zealand.

Induced disease: Plaques 0.25 to 0.6 mm in diameter.

Thermal inactivation: At 70° to 75° C, time not recorded, probably 30 minutes (pH 6.0).

Literature: Whitehead and Hunter, Jour. Path. and Bact., *44*, 1937, 337–347.

Strains: One variant has been described and distinguished from the type variety, *typicus* H. (*loc. cit.*, 158):

29a. *Phagus streptococci* var. *virilis* H. (*loc. cit.*, 158). From Latin *virilis*, vigorous. Common name: Strain RW1 of streptococcus bacteriophage RW. Differing from the type variety in being able to increase at the expense of strain RW1 of *Streptococcus cremoris* (Whitehead and Hunter, Jour. Path. and Bact., *44*, 1937, 337–347).

30. **Phagus maculans** *spec. nov.* From Latin *maculare*, to speckle, in reference to tiny plaques produced by this bacteriophage.

Common name: Streptococcus bacteriophage A.

Hosts: Streptococcus 646, 751, 775.

Geographical distribution: United States (Massachusetts).

Induced disease: Plaques exceedingly minute, scarcely visible to the unaided eye.

Serological relationships: Specific antisera neutralize but there is no cross reaction with respect to streptococcus bacteriophage B, C, or D.

Thermal inactivation: At 60° C in 1 hour.

Other properties: Withstands storage at about 5° C for at least 145 days with but little loss of virulence.

Literature: Evans, Science, *80*, 1934, 40–41; U.S.P.H.S., Public Health Reports, *49*, 1934, 1386–1401.

31. **Phagus lacerans** *spec. nov.* From Latin *lacerare*, to tear, in reference to ragged edges of plaques produced by this bacteriophage.

Common name: Streptococcus bacteriophage B.

Hosts: Streptococcus 563,639: *Streptococcus mucosus* Howard and Perkins.

Insusceptible species: *Streptococcus erysipelatos* Rosenbach.

Geographical distribution: United States (Wisconsin).

Induced disease: Medium size plaques, the largest about 3 mm in diameter, edges ragged, centers clean.

Serological relationships: Specific neutralization, but no cross reactions with streptococcus bacteriophages A, C, and D.

Thermal inactivation: At 60° C in 1 hour.

Other properties: Withstands storage at about 5° C for at least 261 days.

Literature: Clark and Clark, Jour. Bact., *11*, 1926, 89; Proc. Soc. Exp. Biol. and Med., *24*, 1927, 635–639; Colvin, Jour. Inf. Dis., *51*, 1932, 17–29; Evans, U.S.P.H.S., Public Health Reports, *49*, 1934, 1386–1401; Jour. Bact., *39*, 1940, 597–604; Shwartzman, Jour. Exp. Med., *46*, 1927, 497–509.

32. **Phagus tolerans** *spec. nov.* From Latin *tolerans*, tolerating, in reference to the unusual ability of this streptococcus

bacteriophage to remain viable under certain adverse conditions.

Common name: Streptococcus bacteriophage C.

Hosts: Streptococcus 646, 594, 756, 806.

Geographical distribution: United States (Ohio, Massachusetts, Connecticut).

Induced disease: Small plaques, the largest about 1.0 mm in diameter.

Serological relationships: Specific neutralization, but no cross reactions with streptococcus bacteriophages A, B, and D.

Thermal inactivation: At 63° to 65° C in 1 hour.

Other properties: Withstands storage in 1:200 phenol at about 5° C for at least 261 days; equally resistant to storage in 1:10,000 sodium ethyl mercurithiosalicylate (merthiolate), or to storage without preservatives.

Literature: Evans, U. S. Pub. Health Ser., Public Health Reports, *49*, 1934, 1386–1401.

33. **Phagus michiganensis** *spec. nov.* From name of state, Michigan, where this bacteriophage was first isolated.

Common name: Streptococcus bacteriophage D.

Host: Streptococcus 693.

Geographical distribution: United States (Michigan).

Induced disease: Small plaques, about 0.75 mm in diameter, edges clear-cut, centers clean.

Serological relationships: Specific neutralization, but no cross neutralization with streptococcus bacteriophages A, B, and C.

Thermal inactivation: At 60° to 63° C in 1 hour.

Other properties: Withstands storage at about 5°C for at least 261 days.

Literature: Evans, U. S. Pub. Health Ser., Public Health Reports, *49*, 1934, 1386–1401.

34. **Phagus fragilis**, H. (*loc. cit.*, 159). From Latin *fragilis*, fragile, in reference to easy destruction of this bacteriophage by light and by concentrated urea solutions.

Common names: Staphylococcus bacteriophage Au2, Au3, Au4, or D, perhaps bacteriophage H of Gratia.

Hosts: *Staphylococcus aureus* Rosenbach and *Staphylococcus albus* Rosenbach.

Geographical distribution: United States.

Induced disease: Small plaques, 0.2 to 1.0 mm in diameter, with sharp edges.

Serological relationships: Cross-neutralization reactions with staphylococcus bacteriophages Au1, Au3, Au4, and D, but not with staphylococcus bacteriophages Au21, Au12, A, B, C, or bacteriophage C16.

Thermal inactivation: At about 57° C in 30 minutes.

Other properties: Particle diameter 50 to 75 millimicrons. Readily inactivated photodynamically. Completely inactivated by 27 per cent urea solution in 1 hour at 37° C. Lysis not inhibited even by 1.5 per cent sodium citrate in agar medium.

Literature: Burnet and Lush, Jour. Path. and Bact., *40*, 1935, 455–469; Burnet and McKie, Austral. Jour. Exp. Biol. and Med. Sci., *6*, 1929, 21–31; Fisk, Jour. Inf. Dis., *71*, 1942, 153–160.

35. **Phagus intermedius** H. (*loc. cit.*, 160). From Latin *intermedius*, intermediate, in reference to position of this bacteriophage between staphylococcus bacteriophages that multiply readily in broth cultures of host organisms and those that do not.

Common name: Staphylococcus bacteriophage Au21.

Host: *Staphylococcus aureus* Rosenbach.

Geographical distribution: Australia.

Induced disease: Small plaques, 0.1 to 0.3 mm in diameter, with sharp edges.

Serological relationships: Specific neutralization reaction but no cross-neutralization reaction with staphylococcus bacteriophages Au2 or Au12.

Other properties: Not readily inactivated photodynamically; completely inactivated by 27 per cent urea solution in 1 hour at 37° C; lysis inhibited by 1 per cent sodium citrate in agar medium but not by 0.5 per cent or lower concentrations.

Literature: Burnet and Lush, Jour. Path. and Bact., *40*, 1935, 455–469.

36. **Phagus caducus** H. (*loc. cit.*, 160). From Latin *caducus*, perishable, in reference to the easy destruction of this bacteriophage by concentrated urea solutions.

Common name: Staphylococcus bacteriophage Au12.

Host: *Staphylococcus aureus* Rosenbach.

Geographical distribution: Australia.

Induced disease: Small plaques, 0.2 to 0.5 mm in diameter, with sharp edges.

Serological relationships: Cross-neutralization reactions with staphylococcus bacteriophages Au11 and Au13, but not with staphylococcus bacteriophages Au2, Au21, A, and C. Antiserum to staphylococcus bacteriophage B gives no neutralization of Au12, though the reciprocal reaction occurs to 1:200 dilution.

Other properties: Not readily inactivated photodynamically; completely inactivated by 27 per cent urea solution in 1 hour at 37° C; lysis inhibited by as little as 0.25 per cent sodium citrate in agar.

Literature: Burnet and Lush, Jour. Path. and Bact., *40*, 1935, 455–469.

37. **Phagus alpha** H. (*loc. cit.*, 161). From Greek equivalent of common name.

Common name: Staphylococcus bacteriophage A.

Host: *Staphylococcus albus* Rosenbach.

Geographical distribution: Australia.

Induced disease: Plaques of medium size, 1.5 to 2.5 mm in diameter, with hazy periphery.

Serological relationships: Specific neutralization reaction, but no cross-neutralization reactions with staphylococcus bacteriophages Au2, B, or C.

Immunological relationships: Colonies of *Staphylococcus albus* appearing after lysis with this bacteriophage are resistant to staphylococcus bacteriophages B, C, and D.

Thermal inactivation: At 68° to 70° C in 30 minutes.

Other properties: Not readily inactivated photodynamically; not completely inactivated by 27 per cent urea solution in 1 hour at 37° C; lysis not inhibited even by 1.5 per cent sodium citrate in agar.

Literature: Burnet and Lush, Jour. Path. and Bact., *40*, 1935, 455–469; Burnet and McKie, Austral. Jour. Exp. Biol. and Med. Sci., *6*, 1929, 21–31.

38. **Phagus beta** H. (*loc. cit.*, 162). From Greek equivalent of common name.

Common name: Staphylococcus bacteriophage B.

Host: *Staphylococcus albus* Rosenbach.

Geographical distribution: Australia.

Induced disease: Plaques of medium size, 0.7 to 1.5 mm in diameter, with sharp edges.

Serological relationships: Specific neutralization reaction, but no cross-neutralization reaction with respect to staphylococcus bacteriophages Au2, Au12, A, or C, except that antiserum made with Au12 neutralizes this bacteriophage in low dilutions (See *Phagus caducus*).

Immunological relationships: Colonies appearing after lysis of *Staphylococcus albus* with this bacteriophage furnish organisms susceptible to staphylococcus bacteriophages A and D.

Thermal inactivation: At 63° to 65° C in 10 minutes.

Other properties: Readily inactivated photodynamically; completely inactivated by 27 per cent urea solution in 1 hour at 37° C; lysis not inhibited even by 1.5 per cent sodium citrate in agar medium.

Literature: Burnet and Lush, Jour. Path. and Bact., *40*, 1935, 455–469; Burnet

and McKie, Austral. Jour. Exp. Biol. and Med. Sci., *6*, 1929, 21–31.

39. **Phagus durabilis** H. (*loc. cit.*, 162). From Latin *durabilis*, lasting, in reference to the stability of this bacteriophage in concentrated urea solution and other unfavorable media.

Common name: Staphylococcus bacteriophage C.

Host: *Staphylococcus albus* Rosenbach.

Geographical distribution: Australia.

Induced disease: Plaques 2.0 to 3.0 mm in diameter. Vitreous change in peripheral zone.

Serological relationships: Cross-neutralization reaction with staphylococcus bacteriophage C′, and less strongly with B, but not with Au2 or A.

Immunological relationships: Colonies of *Staphylococcus albus* appearing after lysis with this bacteriophage furnish organisms resistant to it but susceptible to staphylococcus bacteriophages A, B, and D.

Thermal inactivation: At 61° to 63° C in 30 minutes.

Other properties: Not readily inactivated photodynamically; not completely inactivated by 27 per cent urea solution in 1 hour at 37° C; lysis not inhibited even by 1.5 per cent sodium citrate in agar medium.

Literature: Burnet and Lush, Jour. Path. and Bact., *40*, 1935, 455–469; Burnet and McKie, Austral. Jour. Exp. Biol. and Med. Sci., *6*, 1929, 21–31; Rakieten et al., Jour. Bact., *32*, 1936, 505–518.

40. **Phagus liber** H. (*loc. cit.*, 163). From Latin *liber*, independent, in reference to demonstrated independence of this virus, its bacterial host, and its dipterous superhost, in respect to origin.

Common name: *Staphylococcus muscae* bacteriophage.

Host: *Staphylococcus muscae* Glaser.

Geographical distribution: United States.

Induced disease: Lysis in broth cultures; plaques in agar cultures, but characteristics of plaques not recorded.

Thermal inactivation: At a little above 50° C in 5 minutes.

Other properties: A characteristic nucleoprotein has been isolated from lysed staphylococci. Sedimentation constant, 650 × 10^{-13} cm $dyne^{-1}$ $sec.^{-1}$, corresponding to a molecular weight of about 300,000,000. Denatured at acidities beyond pH 5.0. Digested by chymotrypsin, not by trypsin. Apparent density, about 1.20. Diffusion coefficient, varying with dilution.

Literature: Glaser, Amer. Jour. Hygiene, *27*, 1938, 311–315; Northrop, Jour. Gen. Physiol., *21*, 1938, 335–366; Shope, Jour. Exp. Med., *45*, 1927, 1037–1044; Wyckoff, Jour. Gen. Physiol., *21*, 1938, 367–373.

41. **Phagus cholerae** H. (*loc. cit.*, 164). From former name of host.

Common name: *Vibrio comma* bacteriophage.

Host: *Vibrio comma* Winslow et al. (formerly *V. cholerae* Neisser); Indian strains usually carry this bacteriophage, but Chinese and Japanese strains lack it, are susceptible, and upon inoculation become lysogenic.

Geographical distribution: India.

Induced disease: In both R and S forms of *Vibrio comma*, no plaques on ordinary agar plates, but vibrios become lysogenic. Egg-white in 1:25 dilution enhances activity enough to allow visible lysis, occasional plaques, or stippling at the site of inoculation.

Immunological relationships: *Vibrio comma* organisms that have been infected with this bacteriophage and are resistant to its further action are still susceptible to cholera bacteriophages A, C, and D.

Literature: White, Jour. Path. and Bact., *44*, 1937, 276–278.

42. **Phagus celer** H. (*loc. cit.*, 164). From Latin *celer*, quick, in reference to relatively quick action of this bacteriophage.

Common name: Cholera bacteriophage A.

Host: *Vibrio comma* Winslow et al., smooth types, except non-agglutinable vibrios.

Geographical distribution: India.

Induced disease: Lysis in 2 hours, followed by abundant secondary growth. Only smooth elements of the culture are attacked.

Serological relationships: Antigenically distinct from cholera bacteriophage C.

Immunological relationships: Secondary growth resistant to this virus, but susceptible to cholera bacteriophages C and D.

Other properties: Selectively inactivated by specific polysaccharide of smooth strains, not by a lipoid emulsion that is effective against cholera bacteriophage C. Active in dilution of $1:10^9$ or $1:10^{10}$. Multiplication rate, $n \times 10^5$ in 2 hours.

Literature: Asheshov et al., Indian Jour. Med. Res., *20*, 1933, 1127–1157; White, Jour. Path. and Bact., *43*, 1936, 591–593.

43. **Phagus effrenus** H. (*loc. cit.*, 165). From Latin *effrenus*, unbridled, in reference to the ability of this bacteriophage to attack all tested strains of the cholera organism.

Common name: Cholera bacteriophage C.

Host: *Vibrio comma* Winslow et al., all strains.

Geographical distribution: India.

Induced disease: Sometimes death without lysis. When lysis occurs, it is rarely complete and is followed by secondary resistant growth.

Serological relationships: Antigenically distinct from cholera bacteriophage A.

Immunological relationships: Secondary growth resistant to this bacteriophage, but susceptible to cholera bacteriophages A and D.

Other properties: Selectively inactivated by lipoid from smooth strain of host, but not by specific polysaccharide. Active in dilution of $1:10^8$ or $1:10^{10}$. Multiplication rate, $n \times 10^1$ in 2 hours.

Literature: Asheshov et al., Indian Jour. Med. Res., *20*, 1933, 1127–1157; White, Jour. Path. and Bact., *43*, 1936, 591–593.

44. **Phagus lentus** H. (*loc. cit.*, 166). From Latin *lentus*, slow, in reference to the relatively slow and incomplete lysis induced by this bacteriophage.

Common name: Cholera bacteriophage D.

Host: *Vibrio comma* Winslow et al.

Geographical distribution: India.

Induced disease: Incomplete lysis in about 5 hours, followed, in rough cultures, by slow development of resistant secondary growth.

Immunological relationships: Secondary growth resistant to this bacteriophage, but susceptible to cholera bacteriophages A and C.

Other properties: Not inactivated by specific polysaccharide effective against cholera bacteriophage A, nor by lipoid effective against cholera bacteriophage C. Multiplication rate, $n \times 10^2$ in 2 hours.

Literature: Asheshov et al., Indian Jour. Med. Res., *20*, 1933, 1127–1157; White, Jour. Path. and Bact., *43*, 1936, 591–593.

45. **Phagus diphtheriae** H. (*loc. cit.*, 167). From name of host.

Common name: *Corynebacterium diphtheriae* bacteriophage.

Host: *Corynebacterium diphtheriae* Lehmann and Neumann, many strains, especially 122 of 127 Australian type II *gravis* isolates; type I *gravis* isolates are lysogenic (carriers); all intermediate isolates are susceptible.

Insusceptible species: *Corynebacterium diphtheriae*, all tested *mitis* isolates, except 2 lysogenic. A strain of *C. diphtheriae* from Swan Hill, 200 miles north of Melbourne, was found to be resistant to this bacteriophage and to the small-

plaque diphtheria bacteriophage, *P. futilis*.

Geographical distribution: Australia.

Induced disease: In *Corynebacterium diphtheriae* on agar, plaques 1.0 to 1.5 mm in diameter, with shelving edge. A few resistant bacterial colonies often appear in the central clear area.

Literature: Keogh et al., Jour. Path. and Bact., *46*, 1938, 565–570; Smith and Jordan, Jour. Bact., *21*, 1931, 75–88; Stone and Hobby, Jour. Bact., *27*, 1934, 403–417.

46. **Phagus futilis** H. (*loc. cit.*, 168). From Latin *futilis*, vain, in reference to regular appearance of resistant organisms in plaques on agar cultures lysed by this bacteriophage.

Common name: Small-plaque diphtheria bacteriophage.

Host: *Corynebacterium diphtheriae* Lehmann and Neumann, *gravis* type I isolates and all but 5 *gravis* type II isolates.

Insusceptible species: All tested intermediate and *mitis* strains of *C. diphtheriae*.

Geographical distribution: Australia.

Induced disease: In *Corynebacterium diphtheriae* on agar, pin-point plaques or confluent plaques, with confluent growth of secondary, resistant organisms.

Literature: Keogh et al., Jour. Path. and Bact., *46*, 1938, 565–570.

Suborder II. **Phytophagineae** *subordo novus.*

Viruses infecting higher plants; vectors typically homopterous or hemipterous insects (leafhoppers, aphids, white flies, true bugs) or thysanopterous insects (thrips). From Greek *phagein*, to eat, and *phyton*, a plant.

Key to the families of suborder **Phytophagineae.**

1. Inducing yellows-type diseases; vectors typically cicadellid or fulgorid leafhoppers.
   Family I. *Chlorogenaceae*, p. 1145.
2. Inducing mosaic diseases; vectors typically aphids.
   Family II. *Marmoraceae*, p.1163.
3. Inducing ringspot diseases; vectors unknown.
   Family III. *Annulaceae*, p. 1212.
4. Inducing leaf-curl diseases; vectors typically white flies.
   Family IV. *Rugaceae*, p. 1218.
5. Inducing leaf-savoying diseases; vectors, true bugs.
   Family V. *Savoiaceae*, p. 1221.
6. Inducing spotted wilt; vectors, thrips.
   Family VI. *Lethaceae*, p. 1223.

FAMILY I. CHLOROGENACEAE HOLMES EMEND.

(Handb. Phytopath. Viruses, 1939, 1.)

Viruses of the Yellows-Disease Group; pathogenic in flowering plants, causing diseases in which effects on chlorophyll are usually diffuse or stripe-like, no typical spotting or spotty mottling being involved. Vectors, so far as known, leafhoppers (*CICADELLIDAE* and *FULGORIDAE*).

Key to the genera of family **Chlorogenaceae.**

I. True Yellows Group. Viruses inducing diseases usually characterized by stimulation of normally dormant and adventitious buds to produce numerous slender shoots with long internodes and by chlorosis without spotting; invaded parts abnormally erect in habit. Vectors cicadellid leafhoppers so far as known.
   Genus I. *Chlorogenus*, p. 1146.

II. Peach X-Disease Group. Viruses inducing diseases characterized by rosetting of foliage and sometimes death of host.
   Genus II. *Carpophthora*, p. 1151.

III. Phloem-Necrosis Group. Viruses inducing diseases characterized by progressive degeneration of the host plant or by wilting and sudden death; sometimes by root discoloration. Vectors cicadellid leafhoppers so far as known.
   Genus III. *Morsus*, p. 1153.

IV. Yellow-Dwarf Group. Viruses inducing diseases characterized by chlorotic effects somewhat resembling true mottling but often more diffuse. Vectors cicadellid (agallian) leafhoppers.
   Genus IV. *Aureogenus*, p. 1154.

V. Fiji-Disease Group. Viruses inducing diseases characterized by marked vascular proliferation. The vector of one is known to be a leafhopper of the subfamily Delphacinae, family *FULGORIDAE*.
   Genus V. *Galla*, p. 1157.

VI. Stripe-Disease Group. Viruses inducing diseases characterized by chlorotic striping; hosts grasses. Vectors, cicadellid and fulgorid leafhoppers.
Genus VI. *Fractilinea*, p. 1159.

Genus I. **Chlorogenus** *Holmes.*

(*Loc. cit.*, 1.)

Viruses of the Typical Yellows Group, inducing diseases usually characterized by stimulation of normally dormant and adventitious buds to produce numerous slender shoots with long internodes, by chlorosis without spotting, or by both growth of numerous slender shoots and chlorosis. Invaded parts abnormally erect in habit. Affected flowers often virescent. Hosts, dicotyledonous plants. Vectors, so far as known, exclusively cicadellid leafhoppers. Generic name from Greek *chloros*, light green or yellow, and suffix, *gen*, signifying producing, from Greek *genos*, descent.

The type species is *Chlorogenus callistephi* Holmes.

Key to the species of genus **Chlorogenus.**

I. Natural hosts many, in various families of plants.
1. *Chlorogenus callistephi.*
2. *Chlorogenus australiensis.*

II. Known natural hosts relatively few.
A. Natural hosts rosaceous.
3. *Chlorogenus persicae.*
B. Natural hosts solanaceous.
4. *Chlorogenus solani.*
C. Natural host sandal.
5. *Chlorogenus santali.*
D. Natural host cranberry.
6. *Chlorogenus vaccinii.*
E. Natural host locust.
7. *Chlorogenus robiniae.*
F. Natural host alfalfa.
8. *Chlorogenus medicaginis.*
G. Natural host hop.
9. *Chlorogenus humuli.*

1. **Chlorogenus callistephi** Holmes. (Handb. Phytopath. Viruses, 1939, 2.) From New Latin *Callistephus*, generic name of the China aster.

Common names: Aster-yellows virus, lettuce white-heart virus, *Erigeron*-yellows virus.

Hosts: *Callistephus chinensis* Nees, the China aster, is the host that has been studied most. 170 or more species in 38 different families of dicotyledonous plants have been shown susceptible. Lettuce, endive, carrot, buckwheat, parsnip, and New Zealand spinach are among the hosts of economic importance.

Insusceptible species: All tested species of the family *Leguminosae* and some species of all other tested families have appeared naturally immune.

Geographical distribution: U. S., Canada, Bermuda, Japan, and Hungary. In California the celery-yellows strain of this virus replaces the type.

Induced disease: In most host species the characteristics of disease are clearing of veins, followed by chlorosis of newly formed tissues, stimulation of normally dormant buds to growth, malformation, virescence of flowers, sterility, and upright growth habit. Stimulation of nor

mally dormant buds to adventitious growth and abnormally erect habit are the most constant features. Chlorosis is absent or inconspicuous in some hosts.

Transmission: By leafhopper, *Macrosteles divisus* (Uhl.) (= *Cicadula sexnotata* (Fall.), *C. divisa* (Uhl.)) (*CICADELLIDAE*). Incubation period, about 2 weeks. Some strains of this virus are transmitted also by the leafhoppers *Thamnotettix montanus* Van D. and *T. geminatus* Van D. (*CICADELLIDAE*). By grafting. By dodder. Not through seeds of diseased plants. Not by mechanical inoculation of plants, but virus has been passed from insect to insect mechanically in *Macrosteles divisus;* juice from viruliferous insects contains little virus just after inoculation, but the effective concentration increases at least 100-fold between the 2nd and 12th day of a 17-day incubation period; it seems greatest before the insects begin to infect the aster plants on which they are maintained.

Thermal inactivation: In juice from viruliferous insects, at about 40° C in 10 minutes; at 25° C in 2 to 3 hours. In plant tissues, at 38° to 42° C, in 2 to 3 weeks; cured plants fully susceptible to reinfection. In insect vector, *M. divisus*, at 31° C in 12 days.

Other properties: Virus in juices derived from insects is more stable at 0° C than at 25° C or when frozen; at 0° C it withstands storage 24, not 48, hours in 0.85 per cent NaCl solution at pH 7.0 but most of the virus is inactivated in this time; it withstands dilution 1:1000 in neutral 0.85 per cent NaCl solution; for brief (less than 5-minute) exposures, it remains viable over the range from pH 5 to 9.

Literature: Black, Phytopath., *31*, 1941, 120–135; *33*, 1943, 2 (Abst.); Johnson, *ibid.*, *31*, 1941, 649–656; Kunkel, Am. Jour. Bot., *13*, 1926, 646–705; Contrib. Boyce Thompson Inst., *3*, 1931, 85–123; *4*, 1932, 405–414; Am. Jour. Bot., *24*, 1937, 316–327; *28*, 1941, 761–769; Linn, Cornell Agr. Exp. Sta. (Ithaca), Bull. 742, 1940; Ogilvie, Bermuda Dept. Agr., Agr. Bull. 6, 1927, 7–8; Severin, Hilgardia, *3*, 1929, 543–583; Phytopath., *20*, 1930, 920–921; Hilgardia, *7*, 1932, 163–179; *8*, 1934, 305–325, 339–361; Phytopath., *30*, 1940, 1049–1051; Hilgardia, *14*, 1942, 411–440; Severin and Haasis, Hilgardia, *8*, 1934, 329–335.

Strains: Two variant strains, one found in nature, the other derived experimentally, have been given varietal names to distinguish them from the type variety, *vulgaris* H. (*loc. cit.*, 2):

1a. *Chlorogenus callistephi* var. *californicus* H. (*loc. cit.*, 3). From California, name of state in which this strain was first recognized. Common name: Celery-yellows strain of aster-yellows virus. Differing from the type variety by ability to infect celery (*Apium graveolens* L.—*UMBELLIFERAE*) and zinnia (*Zinnia elegans* Jacq.—*COMPOSITAE*) (Kunkel, Contrib. Boyce Thompson Inst., *4*, 1932, 405–414; Severin, Hilgardia, *3*, 1929, 543–583; *8*, 1934, 305–325).

1b. *Chlorogenus callistephi* var. *attenuatus* H. (*loc. cit.*, 4). From Latin *attenuatus*, weakened. Common name: Heat-attenuated strain of aster-yellows virus. Differing from the type variety by inducing less severe chlorosis and less uprightness of new growth in affected aster plants (Kunkel, Am. Jour. Bot., *24*, 1937, 316–327).

2. **Chlorogenus australiensis** *comb. nov.* From Australia, name of continent. Synonym: *Galla australiensis* H. (*loc. cit.*, 107).

Common names: Tomato big-bud virus; virescence virus; perhaps also stowboor virus, tobacco stolbur or montar virus, eggplant little-leaf virus.

Hosts: *SOLANACEAE—Datura stramonium* L., Jimson weed; *Lycopersicon esculentum* Mill., tomato; *Nicotiana tabacum* L., tobacco; *Solanum melongena* L., eggplant; *S. nigrum* L., black nightshade. Recently a long list of species in this and

other families have been reported as susceptible to virescence virus, presumed to be an isolate of tomato big-bud virus. (Hill, Jour. Counc. Sci. Ind. Res., *16*, 1943, 85–92).

Geographical distribution: Australia, especially New South Wales; viruses causing somewhat similar diseases have been reported also from the Crimea and the northwestern United States.

Induced disease: In tomato, flowers erect, virescent, calyx bladder-like, pollen sterile; floral proliferation. Growth of axillary shoots stimulated. New leaves progressively smaller. Youngest leaves yellowish-green in color, especially at their margins; usually purplish underneath. Hypertrophy of inner phloem. No intracellular inclusions. Fruit reddens imperfectly and becomes tough and woody. Roots appear normal. In *Solanum nigrum*, axillary shoots numerous, leaves small, internal phloem adventitious. In tobacco, plants dwarfed; leaves recurved, distorted, twisted, thickened, brittle, yellowish green, hanging down close to stem; small leaves on shoots from axillary buds; proliferation and virescence of flowering parts; chlorotic clearing of veins as early effect of disease; upper surface of foliage appears glazed; some necrosis of veins, in old leaves, near tips and margins or on midrib; viable seed rarely produced; calyx bladder-like, floral axis may form short branches bearing small leaves; disease sometimes called bunchy top.

Transmission: By leafhopper, *Thamnotettix argentata* Evans (*CICADELLIDAE*). Experimentally by budding and other methods of grafting. Not by inoculation of expressed juice.

Literature: Cobb, Agr. Gaz. New South Wales, *13*, 1902, 410–414; Dana, Phytopath., *30*, 1940, 866–869; Hill, Jour. Austral. Inst. Agr. Sci., *6*, 1940, 199–200; Jour. Council Sci. Ind. Res., *10*, 1937, 309–312; *16*, 1943, 85–92; Michailowa, Phytopath., *25*, 1935, 539–558; Rischkov et al., Ztschr. Pflanzenkr., *43*, 1933, 496–498; Samuel et al., Phytopath., *23*, 1933, 641–653.

3. **Chlorogenus persicae** H. (*loc. cit.*, 5). From New Latin *Persica*, former generic name of peach.

Common names: Peach-yellows virus, little-peach virus.

Hosts: *ROSACEAE—Prunus persica* (L.) Batsch, peach; *P. salicina* Lindl., Japanese plum; and all other tested species of the genus *Prunus*.

Geographical distribution: Eastern United States and Canada, south to North Carolina. First occurred near Philadelphia in this country. Origin perhaps oriental; introduction in oriental plums suspected. Not in Europe.

Induced disease: In peach, clearing of veins, production of thin erect shoots bearing small chlorotic leaves, followed by death in a year or two. In early stages of the disease there is premature ripening of fruit. In Japanese plum, systemic infection but no obvious symptoms.

Transmission: By the leafhopper, *Macropsis trimaculata* (Fitch) (*CICADELLIDAE*). By budding; virus spreads down stem from point of bud insertion faster than up. Not by inoculation of expressed juice, despite numerous attempts. Not by pollen of diseased trees.

Immunological relationships: Presence of peach-yellows virus immunizes tree against little-peach virus, formerly considered an independent entity.

Thermal inactivation: In peach tissues, at 34° to 35° C in 4 to 5 days; at 44° C in 30 minutes; at 47° C in 10 minutes; at 50° C in 3 to 4 minutes; at 56° C in 15 seconds.

Other properties: Trees and bud sticks may be treated safely with heat sufficient to kill the virus. Cured trees are susceptible to reinfection.

Literature: Blake, N. J. Agr. Exp. Sta., Bull. 226, 1910; Kunkel, Contrib. Boyce Thompson Inst., *5*, 1933, 19–28; Phytopath., *26*, 1936, 201–219, 809–830; *28*, 1938, 491–497; Manns, Trans. Peninsula Hort. Soc., *23*, 1933, 17–19; Manns and Manns,

ibid., *24*, 1934, 72–76; McCubbin, Pennsylvania Dept. Agr., Gen. Bull. *382*, 1924.

Strains: Numerous strains of peach-yellows virus probably exist in nature. One of these has been given a varietal name, distinguishing it from the type variety, *vulgaris* H. (*loc. cit.*, 5):

3a. *Chlorogenus persicae* var. *micropersica* H. (*loc. cit.*, 6). From Greek *micros*, small, and New Latin *Persica*, former generic name of peach. Common name: Little-peach strain of peach-yellows virus. Differing from the type variety by tendency to cause a mild type of disease, characterized by distortion of young leaves, production of many short branches on main trunk, later yellowing of mature leaves, twiggy growth, shoots slightly less erect than in typical peach yellows. (Kunkel, Phytopath., *26*, 1936, 201–219; *26*, 1936, 809–830; *28*, 1938, 491–497; Manns, Trans. Peninsula Hort. Soc., *23*, 1933, 17–19; *24*, 1934, 72–76.)

4. **Chlorogenus solani** H. (*loc. cit.*, 7). From New Latin *Solanum*, generic designation of potato. Synonym: *Chlorophthora solani* McKinney, Jour. Washington Acad. Sci., *34*, 1944, 151.

Common names: Potato witches'-broom virus, potato wilding or semi-wilding virus.

Hosts: *SOLANACEAE—Solanum tuberosum* L., potato. Experimentally, also *SOLANACEAE—Lycopersicon esculentum* Mill., tomato; *Nicotiana tabacum* L., tobacco; *N. glutinosa* L.; *N. rustica* L. *APOCYNACEAE—Vinca rosea* L., periwinkle. *CHENOPODIACEAE—Beta vulgaris* L., sugar beet.

Geographical distribution: United States (Montana, Washington), Russia.

Induced disease: In potato, increasingly pronounced flavescence in new leaflets on one or more stems, production of new dwarfed leaflets with marginal flavescence on stems with unusually long internodes and enlarged nodes, growth of spindling axillary and basal branches. profuse blooming and fruiting, lack of dormancy in tuber buds, formation of many small underground tubers as well as some aerial tubers; plants grown from diseased tubers form thread-like stems and small simple leaves; infected plants survive several seasons, with progressive degeneration. In tomato, experimentally, extreme leaf dwarfing, marginal flavescence of leaves and abnormally numerous axillary branches; stems become hollow and die; plants do not survive long after infection. In tobacco, experimentally, slender axillary branches with dwarfed leaves, flowers on spindling pedicels, numerous, small; later leaves flavescent or marginally flavescent.

Transmission: By tuber-core grafts with prepatent period of 29 to 114 days. By stem grafts. By dodder, *Cuscuta campestris* Yuncker (*CONVOLVULACEAE*). Not by inoculation of expressed juice. Not by *Macrosteles divisus* (Uhl.) (*CICADELLIDAE*). No insect vector is known. Not through seeds of diseased tomatoes.

Thermal inactivation: at 42° C in 13 days, in tissues of *Vinca rosea*; at 36° C in 6 days in small potato tubers.

Literature: Hungerford and Dana, Phytopath., *14*, 1924, 372–383; Kunkel, in Virus Diseases, Cornell Univ. Press, Ithaca, N. Y., 1943, 63–82; Proc. Am. Philosoph. Soc., *86*, 1943, 470–475; McLarty, Scient. Agr., *6*, 1926, 395; Whipple, Montana Agr. Exp. Sta., Bull. 130, 1919; Young, Science, *66*, 1927, 304–306; Am. Jour. Bot., *16*, 1929, 277–279; Young and Morris, Jour. Agr. Res., *36*, 1928, 835–854.

5. **Chlorogenus santali** H. (*loc. cit.*, 8). From New Latin *Santalum*, generic designation of sandal.

Common names: Sandal spike-disease virus, sandal spike-rosette virus.

Hosts: *SANTALACEAE—Santalum album* L., sandal. Spike-like diseases have been found also in *RHAMNEAE—Zizyphus oenoplia* Mill., *SAPINDACEAE—Dodonaea viscosa* Jacq., *VER-*

BENACEAE—Stachytarpheta indica Vahl, and *APOCYNACEAE—Vinca rosea* L.

Geographical distribution: South India.

Induced disease: In sandal, abnormally profuse blooming at first, suppression of blooming later; reduction in leaf size and internode length; death ensues in the third year or earlier. In all but the youngest leaves of affected branches, vacuolate intracellular bodies with definite peripheral membrane, 4 to 9 microns in maximum diameter, are found.

Transmission: By twig grafts, inserted buds, and patch grafts, with success decreasing in the order named. Prepatent period 3 to 4 months. Best results in May and June; poorest in October. Perhaps through seeds, but not through pollen of diseased plants. Insect transmission claimed, but species not identified. Reported transmission by *Moonia albimaculata* (*CICADELLIDAE*) requires further confirmation. Not by inoculation of expressed juice. Not by root grafts.

Literature: Coleman, Mysore Dept. Agr., Mycol. Ser., Bull. 3, 1917; Indian Forester, *49*, 1923, 6–9; Dover, *ibid.*, *60*, 1934, 505–506; Narasimhan, Phytopath., *23*, 1933, 191–202; Rangaswami and Sreenvasaya, Current Science, *4*, 1935, 17–19; Sreenvasaya, Nature, *126*, 1930, 957; Venkata Rao and Gopala Iyengar, Mysore Sandal Spike Invest. Comm., Bull. 4, 1934, 1–12; Indian Forester, *60*, 1934, 689–701.

6. **Chlorogenus vaccinii** H. (*loc. cit.*, 10). From New Latin *Vaccinium*, generic designation of cranberry.

Common names: Cranberry false-blossom virus, Wisconsin false-blossom virus.

Hosts: *ERICACEAE—Vaccinium macrocarpon* Ait., cranberry; *V. oxycoccus* L. Experimentally, also *APOCYNACEAE—Vinca rosea* L., periwinkle. *COMPOSITAE—Calendula officinalis* L., calendula. *SOLANACEAE—Lycopersicon esculentum* Mill., tomato; *Nicotiana glutinosa* L.; *N. tabacum* L., tobacco; *Solanum tuberosum* L., potato.

Geographical distribution: Eastern United States and Canada. It is believed that the virus does not spread in bogs with alkaline (pH 7.4 to 8.8) flooding water in Wisconsin though it spreads rapidly in the more productive bogs with nearly neutral (pH 6.0 to 7.0) flooding water.

Induced disease: In cranberry, flowers erect, instead of pendent as in healthy plants; calyx lobes enlarged, petals short, streaked with red and green, stamens and pistils abnormal. Flowers may be replaced by leaves or short branches. Dormancy of axillary buds is broken, producing numerous erect shoots, forming a witches' broom. Diseased fruits small, irregular in shape, erect.

Transmission: By leafhopper, *Ophiola striatula* (Fall.) (=*Euscelis striatulus* (Fall.)) (*CICADELLIDAE*). Not by inoculation of expressed juice. By dodder, *Cuscuta campestris* Yuncker (*CONVOLVULACEAE*).

Thermal inactivation: At 40° C in 2 weeks in tissues of periwinkle.

Literature: Dobroscky, Contrib. Boyce Thompson Inst., *3*, 1931, 59–83; Fracker, Phytopath., *10*, 1920, 173–175; Kunkel, Science, *95*, 1942, 252; Torreya, *43*, 1943, 87–95; Shear, U. S. Dept. Agr., Bull. 444, 1916; Stevens, Phytopath., *15*, 1925, 85–91; *34*, 1944, 140–142; U. S. Dept. Agr., Circular 147, 1931; Stevens and Sawyer, Phytopath., *16*, 1926, 223–227; Wilcox and Beckwith, Jour. Agr. Res., *47*, 1933, 583–590.

7. **Chlorogenus robiniae** H. (*loc. cit.*, 13). From New Latin *Robinia*, generic designation of locust. Synonym: *Polycladus robiniae* McKinney, Jour. Washington Acad. Sci., *34*, 1944, 151.

Common names: Locust witches'-broom virus; locust brooming-disease virus.

Hosts: *LEGUMINOSAE—Robinia pseudoacacia* L., black locust.

Geographical distribution: United

States (southern Pennsylvania to northeastern Georgia, west to southwestern Ohio and Tennessee).

Induced disease: In black locust, clearing of veins, followed by progressive reduction in size of newly formed leaves; growth of spindly shoots to form witches' brooms. Roots more brittle, shorter, and darker than normal, with excessive branching of rootlets, giving the appearance of root brooms.

Transmission: By grafting and budding. Not by inoculation of expressed juice. No insect vector is known.

Literature: Grant et al., Jour. Forestry, *40*, 1942, 253–260; Hartley and Haasis, Phytopath., *19*, 1929, 163–166; Jackson and Hartley, Phytopath., *23*, 1933, 83–90; Waters, Plant World, *1*, 1898, 83–84.

8. **Chlorogenus medicaginis** H. (*loc. cit.*, 14). From New Latin *Medicago*, generic designation of alfalfa (lucerne).

Common names: Alfalfa witches'-broom virus, lucerne witches'-broom virus, spindle-shoot virus, mistletoe virus, Kurrajong virus, bunchy-top virus.

Hosts: *LEGUMINOSAE—Medicago sativa* L., alfalfa (lucerne).

Geographical distribution: Australia, especially New South Wales; perhaps United States.

Induced disease: In alfalfa, plant dwarfed; leaves small, rounded, chlorotic at edge, puckered, distorted; stems short, spindly, numerous. Flowers usually not formed, but sometimes pale and small, sometimes replaced by leafy structures. Seed rarely produced.

Transmission: By grafting. Not by inoculation of expressed juice. No insect vector is known.

Literature: Edwards, Jour. Australian Inst. Agr. Sci., *1*, 1935, 31–32; New South Wales Dept. Agr., Science Bull. 52, 1936; Agr. Gaz. New South Wales, *47*, 1936, 424–426; Richards, U. S. Dept. Agr., Plant Disease Reporter, Supplement, *71*, 1929, 309–310.

9. **Chlorogenus humuli** H. (*loc. cit.*, 15). From New Latin *Humulus*, generic designation of the hop.

Common names: Hop-nettlehead virus, silly-hill disease virus, virus of infectious-sterility of the hop.

Hosts: *MORACEAE—Humulus lupulus* L., European hop.

Geographical distribution: England, Czechoslovakia, Germany, Poland.

Induced disease: In hop, stems numerous, spindly, short, plants weak. Leaves curled upward at margin; cone production greatly reduced.

Transmission: By grafting. Not by inoculation of expressed juice. Not through soil. No insect vector is known.

Literature: Blattný and Vukolov, Rec. Inst. Rech. Agron. Rép. Tchécosl., *137*, 1935, 3–18; Goodwin and Salmon, Jour. Inst. Brew., *33*, 1936, 209–210; Salmon, *ibid.*, *32*, 1935, 235–237; *33*, 1936, 184–186; Salmon and Ware, Jour. South-Eastern Agr. College, Wye, Kent. *37*, 1936, 21–25.

Genus II. Carpophthora *McKinney emend.*

(Jour. Washington Acad. Sci., *34*, 1944, 152.)

Peach X-Disease Group; viruses inducing diseases characterized in general by rosetting of foliage and sometimes death of host. Generic name from Greek, meaning fruit and ruin or destruction.

The type species is *Carpophthora lacerans* McKinney.

Key to the species of genus Carpophthora.

I. Inducing chlorosis, reddening, and tattering of foliage, with rosette formation late in the disease in some hosts.

1. *Carpophthora lacerans*.

II. Inducing rosette formation characteristically, but not tattering of affected foliage.

2. *Carpophthora rosettae.*

1. **Carpophthora lacerans** (Holmes) McKinney. (*Marmor lacerans* Holmes, Handb. Phytopath. Viruses, 1939, 82; McKinney, Jour. Washington Acad. Sci., *34*, 1944, 152.) From Latin *lacerare*, to lacerate, in reference to characteristic foliage injury.

Common name: Peach X-disease virus; virus of peach yellow-red virosis.

Hosts: *ROSACEAE—Prunus persica* (L.) Batsch, peach; *P. virginiana* L., chokecherry.

Geographical distribution: United States, Canada.

Induced disease: In peach, foliage normal each spring but yellowish areas appear in June at base of leaves; affected trees appear lighter green than neighboring healthy trees; discolored spots occur at random on the leaf blade, becoming red and yellow with remainder of leaf becoming chlorotic; the discolored areas usually fall out, leaving the foliage tattered; subsequently, affected leaves drop except at tips of branches; young trees may die, older ones survive indefinitely. Fruit either shrivels and falls or ripens prematurely, with bitter flavor and no viable seed. In chokecherry, conspicuous premature reddening of foliage, development of fruits with dead embryos in the pits; in the second and third seasons after infection, duller colors of foliage, rosettes of small leaves on terminals; death follows the advanced stage of disease.

Transmission: By budding. Not by inoculation of expressed juice. No insect vector has been reported.

Literature: Berkeley, Div. of Botany and Plant Path., Science Service, Dominion Dept. Agr., Ottawa, Canada, Publication *678*, 1941; Boyd, U. S. Dept. Agr., Plant Dis. Rep., *22*, 1938, 334; Hildebrand, Contrib. Boyce Thompson Inst., *11*, 1941, 485–496; Hildebrand and Palmiter, U. S. Dept. Agr., Plant Dis. Rep., *22*, 1938, 394–396; Hildebrand et al., Handbook of virus diseases of stone fruits in North America, Michigan Agr. Exp. Sta., Misc. Publ., 1942, 21–24; Stoddard, Connecticut Agr. Exp. Sta., Circ. *122*, 1938, 54–60; Proc. Connecticut Pomol. Soc., *48*, 1938, 29–32.

2. **Carpophthora rosettae** (Holmes) *comb. nov.* (*Chlorogenus rosettae* H., *nomen nudum*, Phytopath. *29*, 1939, 434; *Nanus rosettae* H., Handb. Phytopath. Viruses, 1939, 125.) From rosette, common name of induced disease, from French, diminutive of *rose*, a rose.

Common name: Peach-rosette virus.

Hosts: *ROSACEAE—Prunus persica* (L.) Batsch, peach; *P. communis* Fritsch, almond; *P. domestica* L., plum. Experimentally, also—*APOCYNACEAE—Vinca rosea* L., periwinkle. *ROSACEAE—P. americana* Marsh., wild plum; *P. armeniaca* L., apricot; *P. cerasus* L., cherry; *P. pumila* L., sand cherry. *SOLANACEAE—Lycopersicon esculentum* Mill., tomato; *Nicotiana glutinosa* L.

Geographical distribution: United States (Georgia, Alabama, South Carolina, Tennessee, West Virginia, Missouri, Oklahoma).

Induced disease: In peach, sudden wilting and death, or growth of abnormally short stems bearing dwarfed leaves with clearing and thickening of veins, followed by death in a few months.

Transmission: By budding. By dodder, *Cuscuta campestris* Yuncker. Not by inoculation of expressed juice. Not through soil. No insect vector is known.

Immunological relationships: No protection is afforded by previous infection of peach trees with *Chlorogenus persicae*, peach-yellows virus.

Thermal inactivation: At 50° C in 10 minutes (in tissues of peach). Rosetted trees are abnormally susceptible to heat

injury and heat treatments cure peach-rosette disease only in recently infected trees.

Literature: Kunkel, Phytopath., *26*, 1936, 201–219, 809–830; in Virus Diseases, Cornell Univ. Press, Ithaca, N. Y., 1943, 63–82; McClintock, Jour. Agr. Res., *24*, 1923, 307–316; Phytopath., *21*, 1931, 373–386; Smith, U. S. Dept. Agr., Div. Veg. Path., Bull. 1, 1891.

Genus III. Morsus *gen. nov.*

Alfalfa-Dwarf Group; viruses inducing diseases characterized in general by sudden wilting and death or by gradual decline of vigor with foliage of darker green color than normal. Vectors, like those of the typical yellows subgroup, cicadellid leafhoppers so far as known. Generic name from Latin *morsus*, sting or vexation.

The type species is *Morsus suffodiens spec. nov.*

Key to the species of genus Morsus.

I. Affecting alfalfa and grape.
 1. *Morsus suffodiens.*

II. Affecting tobacco.
 2. *Morsus reprimens.*

III. Affecting elm.
 3. *Morsus ulmi.*

1. **Morsus suffodiens** *spec. nov.* From Latin *suffodere*, to sap or undermine, in reference to process leading to sudden collapse of long infected, but sometimes not obviously injured, grape vines as well as to progressive decline in size of infected alfalfa plants, the foliage of which may remain green to the last.

Common names: Alfalfa-dwarf virus, lucerne dwarf-disease virus, virus of Pierce's disease of the grape, virus of Anaheim disease.

Hosts: *LEGUMINOSAE—Medicago sativa* L., alfalfa (lucerne). *VITACEAE—Vitis vinifera* L., grape.

Geographical distribution: United States.

Induced disease: In alfalfa, leaves small but green, plant progressively smaller, wood of roots discolored yellow, transpiration decreased; wilting may occur; starch of root diminished; plant eventually succumbs, thinning stand prematurely. In grape, dark green color of leaves retained along veins, not between them, or no abnormality in appearance of foliage; wilting and sudden death of plant in summer of second year. In late summer of first year, there may be dying leaf margins and dying back of cane tips.

Transmission: By budding and root grafting. By leafhoppers, *Draeculacephala minerva* Ball, *Carneocephala fulgida* Nott., *C. triguttata* Nott., *Helochara delta* Oman, *Neokolla circellata* (Baker), *N. gothica* (Sign.), *N. confluens* (Uhler), *N. heiroglyphica* (Say), and *Cuerna occidentalis* Oman and Beamer (*CICADELLIDAE*); these vectors all belong to the subfamily *Amblycephalinae;* all tested species of this, but none of any other, subfamily have proved capable of transmitting this virus. Not by inoculation of expressed juice. Not through soil.

Literature: Frazier, Phytopath., *34*, 1944, 1000–1001; Hewitt, Phytopath., *29*, 1939, 10; *31*, 1941, 862; Blue Anchor, *18*, 1941, 16–21, 36; Hewitt et al., Phytopath., *32*, 1942, 8; Houston et al., Phytopath., *32*, 1942, 10; Milbrath, Calif. Dept. Agr., 20th Ann. Rept., Bull. *28*, 1940, 571; Pierce, U. S. Dept. of Agr., Div. of Veg. Path., Bull. *2*, 1892, 1–222; Weimer, Phytopath., *21*, 1931, 71–75; *27*, 1937, 697–702; Jour. Agr. Res., *47*, 1933, 351–368; *53*, 1936, 333–347; *55*, 1937, 87–104.

2. **Morsus reprimens** *spec. nov.* From Latin *reprimere*, to restrain, check, or curb, in reference to the inhibiting effect on growth of the host plant, tobacco.

Common name: Tobacco yellow-dwarf virus.

Hosts: *SOLANACEAE—Nicotiana tabacum* L., tobacco; *N. rustica* L., Indian tobacco; *N. trigonophylla* Dun. Experimentally, also *N. glauca* Grah. (symptomless) and *N. glutinosa* L.

Geographical distribution: Australia (Victoria, New South Wales, South Australia, and southern Queensland).

Induced disease: In tobacco, internodes of stem shortened, leaves small; downward bending of tips and rolling under of margins of young apical leaves; young leaves darker than normal at first, bunched, later appear ribbed; leaves become yellow-green, pale first between veins; old leaves rugose, thickened, later savoyed. Root system small, roots slightly brown externally and in the region of the phloem. Affected plants may survive the winter and show diseased new growth in the spring.

Transmission: By grafting and budding. By nymphs and adults of the leafhopper, *Thamnotettix argentata* (Evans) (*CICADELLIDAE*).

Literature: Dickson, Australia, Council Sci. Indust. Res., Pamphlet 14, 1929, 22; Hill, Australia, Journal of the Council Sci. Indust. Res., *10*, 1937, 228–230; *14*, 1941, 181–186; *15*, 1942, 13–25.

3. **Morsus ulmi** *spec. nov.* From Latin *ulmus*, elm.

Common name: Elm phloem-necrosis virus.

Host: *URTICACEAE—Ulmus americana* L., American elm.

Geographical distribution: United States (Ohio, Indiana, Illinois, Missouri, Tennessee, Kentucky, and West Virginia).

Induced disease: In elm, gradual decline over a period of 12 to 18 months before death or sudden wilt, drying of leaves, and death within 3 to 4 weeks. All ages susceptible, from seedling to large tree.

Transmission: By patch grafting. Not by inoculation of expressed juice.

Literature: Leach and Valleau, U. S. Dept. Agr., Plant Dis. Rept., *23*, 1939, 300–301; Swingle, Phytopath., *30*, 1940, 23.

Genus IV. **Aureogenus** *Black.*

(Proc. Am. Philos. Soc., *88*, 1944, 141.)

Viruses of the Yellow-Dwarf Group, inducing diseases characterized by yellowing without typical mosaic-type mottling. Vectors agallian leafhoppers (*CICADELLIDAE*). Generic name from Latin *aureus*, yellow or golden, and *genus*, group.

The type species is *Aureogenus vastans* (Holmes) Black.

Key to the species of genus **Aureogenus.**

I. Mechanically transmissible in some hosts by rubbing methods of inoculation. Not producing enlarged veins or club-leaf in clover.
  - 1. *Aureogenus vastans.*

II. Not known to be transmissible by rubbing methods of inoculation.
  - A. Producing enlarged veins in clover.
    - 2. *Aureogenus magnivena.*
  - B. Producing club-leaf in clover.
    - 3. *Aureogenus clavifolium.*

1. Aureogenus vastans (Holmes) Black. (*Marmor vastans* Holmes, Handb. Phytopath. Viruses, 1939, 94; Black, Proc. Am. Philos. Soc., *88*, 1944, 141.) From Latin *vastare*, to devastate.

Common name: Potato yellow-dwarf virus.

Hosts: *SOLANACEAE—Solanum tuberosum* L., potato. *COMPOSITAE—Chrysanthemum leucanthemum* L., var. *pinnatifidum* Lecoq and Lamotte, daisy; *Rudbeckia hirta* L., black-eyed Susan. *CRUCIFERAE—Barbarea vulgaris* R. Br., common winter cress. *LEGUMINOSAE—Trifolium pratense* L., red clover. Experimentally to numerous species in these and other families.

Geographical distribution: Northeastern United States and southeastern Canada.

Induced disease: In potato, yellowing of leaves, necrosis of stem, dwarfing of plant; the stem, if split, shows rusty specks especially at nodes and apex; the apex dies early; tubers are few, small, close to the stem, often cracked, with flesh discolored by scattered brown specks; seed tubers tend to remain unrotted in the ground, becoming hard and glassy; some of them do not germinate in warm soil, others produce shoots that die before reaching the surface, giving poor stands. In *Chrysanthemum leucanthemum* var. *pinnatifidum*, at first, clearing of veins; later, young leaves distorted, thick, stiff, small; petioles short, leaves erect, forming a rosette at the crown of the plant; with passing of the early phases of the disease, foliage tends to appear nearly normal, but remains darker green and more erect than that of healthy plants; virus is recoverable both during and after the period of obvious disease and infected plants may constitute an important reservoir. In *Trifolium incarnatum* L., crimson clover, experimentally, clearing of veins and yellowing of younger leaves (in summer the yellowing is usually replaced in part by an interveinal reddish-brown color on both leaf surfaces extending from the margins inwards); dwarfing of entire plant; death or a chronic disease characterized by milder manifestations without, however, vein enlargement or cupping of leaves. In *Nicotiana rustica* L., experimentally, yellowish primary lesions followed by clearing of veins and systemic chlorosis; the primary lesions facilitate quantitative estimation of concentrations of this virus.

Transmission: By inoculation of expressed juice, in the presence of finely powdered carborundum, to *Nicotiana rustica*; mechanical transmission very difficult in other hosts tested. By grafting. By clover leafhopper, *Aceratagallia sanguinolenta* (Provancher); experimentally, by other closely related leafhoppers, *Aceratagallia lyrata* (Baker), *A. obscura* Oman, and *A. curvata* Oman; not (for the type variety of the virus) by *Agallia constricta* Van Duzee; very rarely by *Agallia quadripunctata* (Provancher) and *Agalliopsis novella* (Say) (*CICADELLIDAE*). The vector *Aceratagallia sanguinolenta* remains infective as an overwintering adult; incubation period not less than 6 days, commonly much longer; virus does not pass to progeny of viruliferous leafhoppers through eggs or sperm; this leafhopper varies genetically in ability to transmit.

Immunological relationships: No protection is afforded against necrotic effects of a testing strain of this virus (var. *lethale* Black) by prior inoculation of *Nicotiana rustica* with isolates of *Marmor medicaginis*, *M. cucumeris*, *M. upsilon*, *Annulus tabaci*, *A. orae*, or *A. dubius*, but the varieties *vulgare* Black and *agalliae* Black protect; these specifically protecting strains give no similar protection against formation of necrotic lesions by subsequently applied isolates of *Marmor tabaci*, *M. lethale*, *Annulus tabaci*, or *A. orae*.

Thermal inactivation: At 50 to 52° C in 10 minutes.

Filterability: Passes Berkefeld W filter.

Other properties: Virus viable at 23 to 27° C less than 13 hours after extraction of juice from diseased plant; not infective after drying in leaf tissues.

Literature: Barrus and Chupp, Phytopath., *12*, 1922, 123–132; Black, Am. Potato Jour., *11*, 1934, 148–152; Cornell Univ. Agr. Exp. Sta., Mem. 209, 1937, 1–23; Phytopath., *28*, 1938, 863–874; Am. Jour. Bot., *27*, 1940, 386–392; Am. Potato Jour., *18*, 1941, 231–233; Phytopath., *33*, 1943, 363–371; Genetics, *28*, 1943, 200–209; Proc. Am. Philos. Soc., *88*, 1944, 132–144; Hansing, Cornell Univ. Agr. Exp. Sta., Bull. 792, 1943; Price and Black, Am. Jour. Bot., *28*, 1941, 594–595; Taylor, Am. Potato Jour., *15*, 1938, 37–40; Walker and Larson, Jour. Agr. Res., *59*, 1939, 259–280; Watkins, Jour. Econ. Ent., *32*, 1939, 561–564; Cornell Univ. Agr. Exp. Sta., Bull. 758, 1941, 1–24; Younkin, Am. Potato Jour., *19*, 1942, 6–11.

Strains: Beside the type variety, *Aureogenus vastans* var. *vulgare* Black (Am. Jour. Bot., *27*, 1940, 391), on which the species is based, two distinctive strains have been given varietal names:

1a. *Aureogenus vastans* var. *agalliae* Black. (Am. Potato Jour., *18*, 1941, 233.) From New Latin *Agallia*, generic name of vector of this strain. Common name: New Jersey strain of potato yellow-dwarf virus. Differing from the type especially in its distinctive vector, the leafhopper, *Agallia constricta* Van Duzee, which is incapable of transmitting the type strain, and in not being transmitted by *Aceratagallia sanguinolenta* (Provancher), common vector of the type variety. Experimentally, transmitted also by *Agallia quadripunctata* (Provancher); perhaps rarely by *Agalliopsis novella* (Say); Differing but little from the type in effects on potato (var. Green Mountain) and *Nicotiana rustica* but more definitely in effects on crimson clover, in affected plants of which a rusty-brown necrosis along the veins, not induced by the type strain, is always present in some degree.

1b. *Aureogenus vastans* var. *lethale* Black. (Am. Jour. Bot., *27*, 1940, 391.) From Latin *lethalis*, causing death. Common name: Strain B5 of potato yellow-dwarf virus. Differing from the type variety especially in a tendency to induce in *Nicotiana rustica*, experimentally, brown primary lesions with necrotic gray centers, systemic yellowing, extensive necrosis of veins, collapse of large areas of leaf, and sometimes death of the host; not known to occur in nature as a separate strain, but readily isolated as a variant from strains collected in nature.

2. **Aureogenus magnivena** Black. (Proc. Am. Philos. Soc., *88*, 1944, 144.) From Latin *magnus*, large, and *vena*, vein.

Common name: Clover big-vein virus.

Host: Experimentally, *LEGUMINOSAE—Trifolium incarnatum* L., crimson clover.

Insusceptible species: *SOLANACEAE—Nicotiana rustica* L., Indian tobacco; *Solanum tuberosum* L., potato.

Geographical distribution: United States (presumably, Washington, D. C.).

Induced disease: In crimson clover, experimentally, unevenly thickened veins which are depressed below the upper surface of the leaf; these enlarged veins, best observed from below, sometimes bear enations that arise from their lower surfaces, leaves often curl upward and inward marginally; in summer, yellowing of leaves progresses from margins inward, the yellow color being later replaced in part by red or purple red; petioles undulating; plants dwarfed; internodes shortened; no clearing of veins; no rusty-brown necrosis.

Transmission: Not by inoculation of expressed juice. By leafhoppers, *Agalliopsis novella* (Say), *Agallia constricta* Van Duzee, *A. quadripunctata* (Provancher); not by *Aceratagallia sanguinolenta* (Provancher) (*CICADELLIDAE*).

3. Aureogenus clavifolium Black. (Proc. Am. Philos. Soc., *88*, 1944, 141.) From Latin *clava*, club, and *folium*, leaf.

Common name: Clover club-leaf virus.

Host: Experimentally, *LEGUMINOSAE—Trifolium incarnatum* L., crimson clover.

Insusceptible species: *SOLANACEAE—Nicotiana rustica* L., Indian tobacco; *Solanum tuberosum* L., potato.

Geographical distribution: United States (Princeton, N. J.).

Induced disease: In crimson clover, experimentally, youngest leaves lighter green than normal, slow to unfold; leaf margins yellowed or colored red or purple red; affected leaves narrow, smooth or savoyed; plant dwarfed, new shoots from leaf axils slightly stimulated; new growth of spindly stems and small leaves; no rusty-brown necrosis of veins, no obvious enlargement of veins, and no obvious clearing of veins at the onset of disease.

Transmission: Not by inoculation of expressed juice. By leafhopper, *Agalliopsis novella* (Say) (*CICADELLIDAE*); not by leafhoppers, *Aceratagallia sanguinolenta* (Provancher), *Agallia constricta* Van Duzee, nor *A. quadripunctata* (Provancher) (*CICADELLIDAE*).

Genus V. Galla *Holmes.*

(*Loc. cit.*, 106)

Viruses of the Fiji-Disease Group, inducing diseases characterized by vascular proliferation. Generic name from Latin *galla*, a gall nut.

The type species is *Galla fijiensis* Holmes.

Key to the species of genus Galla.

I. Infecting sugar cane.
  A. Inducing formation of conspicuous galls.
    1. *Galla fijiensis.*
  B. Not inducing formation of conspicuous galls.
    2. *Galla queenslandiensis.*

II. Infecting anemone.
    3. *Galla anemones.*

III. Infecting peach.
    4. *Galla verrucae.*

IV. Infecting corn.
    5. *Galla zeae.*

1. Galla fijiensis Holmes. (Handb. Phytopath. Viruses, 1939, 106.) From name of Fiji Islands.

Common name: Fiji-disease virus.

Host: *GRAMINEAE—Saccharum officinarum* L., sugar cane.

Geographical distribution: Fiji Islands, New South Wales, Java, Philippine Islands, New Guinea and New Caledonia.

Induced disease: In sugar cane, galls on vascular bundles, formed by proliferation of phloem and nearby cells. Affected cells show characteristic spherical or oval inclusion bodies. Developing leaves shortened, crumpled, abnormally dark green. Infected stools of cane become bushy. Roots small, bunchy.

Transmission: By leafhoppers, *Perkinsiella saccharicida* Kirk. (in Queensland) and *P. vastatrix* Breddin (in Philippine Islands) (*FULGORIDAE*, subfamily *Delphacinae*). Not by grafting. Not by inoculation of expressed juice. Not through eggs of *P. vastatrix*. Cuttings taken from affected canes produce some healthy and some diseased plants, because virus does not become uniformly distributed throughout the host tissues.

Literature: Kunkel, Bull. Exp. Sta., Hawaiian Sugar Planters' Assoc., Bot.

Ser., *3*, 1924, 99–107; Lyon, *ibid.*, *3*, 1921, 1–43; Hawaiian Planters' Rec., *12*, 1915, 200; Mungomery and Bell, Queensland, Bur. Sugar Exp. Sta., Div. Path., Bull. 4, 1933; Ocfemia, Am. Jour. Bot., *21*, 1934, 113–120; Ocfemia and Celino, Phytopath., *29*, 1939, 512–517; Reinking, Phytopath., *11*, 1921, 334–337.

2. **Galla queenslandiensis** H. (*loc. cit.*, 109). From Queensland, where the induced disease was first studied.

Common name: Sugar-cane dwarf-disease virus.

Host: *GRAMINEAE—Saccharum officinarum* L., sugar cane.

Geographical distribution: Queensland.

Induced disease: In sugar cane, young leaves marked with scattered chlorotic streaks, leaves stiff and erect, spindle twisted, abnormally short and pale. As leaves mature, streaks disappear, leaves become darker than normal green. In recently infected plants, vascular bundles are enlarged, irregular in shape, fused and characterized by abnormal proliferation of thin-walled lignified cells.

Literature: Bell, Queensland, Bur. Sugar Exp. Sta., Div. Path., Bull. 3, 1932.

3. **Galla anemones** H. (*loc. cit.*, 108). From Latin *anemone*, anemone or windflower.

Common name: Anemone-alloiophylly virus.

Hosts: *RANUNCULACEAE—Anemone nemorosa* L., vernal windflower; *A. ranunculoides* L.; *A. trifolia* L.

Geographical distribution: Germany.

Induced disease: Leaves thickened and distorted, petioles thickened. Flowers distorted or not formed. Vascular bundles larger and more numerous than in healthy plants. Palisade cells short, chloroplasts smaller and fewer than normal.

Transmission: By needle puncture into rhizomes immersed in filtered juice of diseased plant. By contamination of soil with fragments of diseased leaves or rhizomes.

Literature: Klebahn, Bericht. d. Deutsch. Bot. Gesellsch., *15*, 1897, 527–536; Ztschr. wissensch. Biol., Abt. E, Planta, *1*, 1926, 419–440; *6*, 1928, 40–95; Phytopath. Ztschr., *4*, 1932, 1–36; *9*, 1936, 357–370.

4. **Galla verrucae** Blodgett. (Phytopath., *33*, 1943, 30.) From Latin *verruca*, wart. Originally spelled *verruca*, apparently by a typographical error, which was corrected twice on the following page, once in a statement that the genitive *verrucae* had been given as specific epithet.

Common name: Peach-wart virus.

Host: *ROSACEAE—Prunus persica* (L.) Batsch, peach.

Geographical distribution: United States (Idaho, Washington, Oregon).

Induced disease: In peach, no characteristic effect on foliage. Fruits blistered, welted, later with warty outgrowths conspicuously raised. Affected tissues light tan to red, rough, cracked and russeted, or smooth. Gumming usual, often severe. Warty tissue superficial; underlying tissues coarse, filled with gum pockets, but not abnormal in flavor. Warty tissue may be hard and bony, but more often it is merely tougher than normal.

Transmission: By budding and inarching.

Literature: Blodgett, Phytopath., *31*, 1941, 859–860 (Abst.); *33*, 1943, 21–32.

5. **Galla zeae** McKinney. (Jour. Washington Acad. Sci., *34*, 1944, 328.) From Latin *zea*, a kind of grain.

Common name: Wallaby-ear disease virus.

Host: *GRAMINEAE—Zea mays* L., corn (maize).

Geographical distribution: Southeastern Queensland, Australia.

Induced disease: In corn (maize), small swellings on secondary veins on undersides of young leaves, spreading to base and tip of leaf along veins; plant dwarfed, becoming abnormally deep green and deficient in development of pollen; silk, cobs, and grain retarded in growth.

Transmission: By leafhopper, *Cicadula bimaculata* Evans (*CICADELLIDAE*).

Literature: Schindler, Jour. Austral. Inst. Agr. Sci., *8*, 1942, 35–37.

Genus VI. Fractilinea *McKinney.*

(Jour. Washington Acad. Sci., *34*, 1944, 148.)

Viruses of the Stripe-Disease Group; hosts grasses; insect vectors, cicadellid and fulgorid leafhoppers. Generic name from Latin, meaning interrupted and line.

The type species is *Fractilinea maidis* (Holmes) McKinney.

Key to the species of genus Fractilinea.

I. Vectors, cicadellid leafhoppers.
   1. *Fractilinea maidis.*
   2. *Fractilinea oryzae.*
   3. *Fractilinea tritici.*
   4. *Fractilinea quarta.*

II. Vectors, fulgorid leafhoppers.
   5. *Fractilinea zeae.*
   6. *Fractilinea avenae.*

1. Fractilinea maidis (Holmes) McKinney. (*Marmor maidis* Holmes, Handb. Phytopath. Viruses, 1939, 56; *Fractilinea maidis* McKinney, Jour. Washington Acad. Sci., *34*, 1944, 149.) From New Latin *mays*, corn (i.e. maize).

Common name: Maize-streak virus.

Hosts: *GRAMINEAE—Zea mays* L., corn (maize); *Digitaria horizontalis* Willd., *Eleusine indica* Gaert.; *Saccharum officinarum* L., sugar cane.

Geographical distribution: Africa.

Induced disease: In corn, pale spots at base of young leaf, followed by chlorotic spotting and streaking of subsequently formed leaves. Virus moves rapidly (up to 40 cm in 2 hours at 30° C) after introduction into host plant by insect. More virus in chlorotic spots than in green areas of affected leaves.

Transmission: By leafhoppers, *Cicadulina* (= *Balclutha*) *mbila* (Naude), *C. zeae* China, and *C. storeyi* China (*CICADELLIDAE*). In *C. mbila* ability to transmit this virus is controlled by a sex-linked dominant gene; active male (AX) (Y), inactive male (aX) (Y), inactive female (aX) (aX), active female (AX) (AX) or (AX) (aX). Inactive individuals ingest virus when feeding, but can become infective only if the intestine is wounded purposely or accidentally. If inoculated artificially by introducing virus into blood, both active and inactive insects become infective. Incubation period, 6 to 12 hours at 30° C. Young not infected through the egg. Infective leafhopper cannot transmit virus unless feeding puncture exceeds a minimum period, about 5 minutes in duration. This virus has not been transmitted to its plant hosts by inoculation of expressed juices.

Filterability: At pH 6, passes Chamberland L_1 and L_3, Berkefeld V and N, filters; retained by Seitz E K filter disc.

Literature: Storey, Ann. Appl. Biol., *12*, 1925, 422–439; *15*, 1928, 1–25; *19*, 1932, 1–5; Proc. Roy. Soc., B, *112*, 1932, 46–60; *113*, 1933, 463–485; *125*, 1938, 455–477; Ann. Appl. Biol., *21*, 1934, 588–589; *24*, 1937, 87–94; East Afr. Agr. Jour., *1*, 1936, 471–475; Storey and McClean, Ann. Appl. Biol., *17*, 1930, 691–719.

Strains: Two strains that differ radically from the type, var. *typicum* H. (*loc. cit.*, 56), have been given varietal names, as follows:

1a. *Fractilinea maidis* var. *sacchari* H. (*loc. cit.*, 57). From New Latin *Saccharum*, generic name of sugar cane. Common name: Cane-streak strain of

maize-streak virus. Differing from the type strain in being specialized for attacking sugar cane, in which the type (from maize) tends to be localized or finally lost with resultant spontaneous recovery of the temporary host. The cane-streak strain usually spreads readily in the cane plant; leaves become much marked with broken, narrow, pale, longitudinal stripes and spots; stems remain unaffected. One variety of sugar cane, P.O.J. 213, is resistant and, if infected, tends to recover. (McClean, Intern. Soc. Sugar Cane Techn., Bull. 27, 1932; Proc. So. Afr. Sugar Techn. Assoc., 1936, 1–11; Storey, Rept. Imp. Bot. Conf., London, 1924, 132–144; Union So. Afr. Dept. Agr., Sci. Bull. 39, 1935; Ann. Appl. Biol., *17*, 1930, 691–719.

1b. *Fractilinea maidis* var. *mitis* H. (*loc. cit.*, 58). From Latin *mitis*, mild. Common name: Mottle strain of maize-streak virus. Differing from the typical strain by the mildness of the disease induced in corn (maize), transitory chlorotic mottling of newly developed leaves, followed by fading of mottling and production of apparently normal leaves. Young leaves, while mottled, are less rigid than normal and may not remain as nearly erect as healthy leaves. (Storey, Ann. Appl. Biol., *24*, 1937, 87–94.)

2. **Fractilinea oryzae** (Holmes) *comb. nov.* (*Marmor oryzae* Holmes, *loc. cit.*, 64.) From Latin *oryza*, rice.

Common name: Rice dwarf-disease virus.

Hosts: *GRAMINEAE—Oryza sativa* L., rice. Experimentally, also *Alopecurus fulvus* L.; *Avena sativa* L., oat; *Echinochloa crusgalli* Beauv. var. *edulis* Honda; *Panicum miliaceum* L.; *Poa pratensis* L.; *Secale cereale* L., rye; *Triticum vulgare* Vill., wheat.

Insusceptible species: *GRAMINEAE —Zea mays* L., corn (maize); *Hordeum vulgare* L., barley; *Setaria italica* Beauv., foxtail millet; *Andropogon sorghum* Brot. (= *Holcus sorghum* L.), sorghum.

Geographical distribution: Japan, Philippine Islands.

Induced disease: In rice, yellowish green spots along veins of young leaf, followed by chlorotic spotting and streaking of subsequently formed leaves. Growth stunted, internodes and roots abnormally short, forming a dwarf plant. Vacuolate intracellular bodies, 3 to 10 by 2.5 to 8.5 microns in size, close to nuclei of cells in affected tissues.

Transmission: By leafhoppers, *Nephotettix apicalis* var. *cincticeps* Uhler, *N. bipunctatus* Fabr., and *Deltocephalus dorsalis* Motsch. (*CICADELLIDAE*). Virus transmitted through some of the eggs but through none of the sperm of infected individuals of *N. apicalis*. Transfer from individuals thus infected through the egg to their progeny likewise demonstrated, even to the 7th generation. This is the only confirmed instance of transmission of a phytopathogenic virus through the eggs of an insect vector and is considered as evidence that the virus multiplies within the body of its vector as well as in its plant hosts. Incubation period in insect usually 30 to 45 days after first feeding on an infected plant, sometimes as short as 10 or as long as 73 days; nymphs from viruliferous eggs do not become infective until 7 to 38 (average 19) days after emergence. Transmission by inoculation of expressed juice has not been demonstrated. No transmission through seeds from diseased rice plants. No soil transmission.

Literature: Agati et al., Philippine Jour. Agr., *12*, 1941, 197–210; Fukushi, Trans. Sapporo Nat. Hist. Soc., *12*, 1931, 35–41; Proc. Imp. Acad., Tokyo, *9*, 1933, 457–460; Jour. Fac. Agr. Hokkaido Imp. Univ., *37*, 1934, 41–164; Trans. Sapporo Nat. Hist. Soc., *13*, 1934, 162–166; Proc. Imp. Acad., Tokyo, *11*, 1935, 301–303; *13*, 1937, 328–331; *15*, 1939, 142–145; Jour. Fac. Agr. Hokkaido Imp. Univ., *45*, 1940, 83–154; Katsura, Phytopath.,

26, 1936, 887–895; Takata, Jour. Japan Agr. Soc., *171*, 1895, 1–4; *172*, 1896, 13–32 (Takata's papers, in Japanese, constitute the first published record of transmission by an insect of a virus causing disease in a plant, the leafhopper *Deltocephalus dorsalis* Motsch. transmitting dwarf-disease virus to rice; see Fukushi, 1937, cited above).

3. **Fractilinea tritici** McKinney. (Jour. Washington Acad Sci., *34*, 1944, 327.) From Latin *triticum*, wheat.

Common name: Winter-wheat mosaic virus.

Hosts: *GRAMINEAE—Triticum aestivum* L., wheat; *Secale cereale* L., rye; *Avena byzantina*; *A. fatua* L., wild oat; *A. sativa* L., oat; *Hordeum vulgare* L., barley.

Geographical distribution: Union of Soviet Socialist Republics.

Induced disease: In winter wheat and rye, chlorotic mottling; profuse branching. In winter wheat, phloem necrosis; chloroplasts few, small; vacuolate inclusions in cells; nuclei enlarged and with extra nucleoli; no protein crystals of the pupation-disease type in affected cells. In spring wheat, barley, and oats, chlorotic mottling without profuse branching; no proliferation of flowers, but grain is rarely formed, most infected plants dying before this stage of growth.

Transmission: By leafhopper, *Deltocephalus striatus* L. (*CICADELLIDAE*), with incubation period of 15 to 18 days. Not by inoculation of expressed juice. Not through soil.

Literature: Zazhurilo and Sitnikova, Compt. rend. Acad. Sci. U. R. S. S., *25*, 1939, 798–801; *26*, 1940, 474–478; *29*, 1940, 429–432; Proc. Lenin Acad. Agr. Sci., U. R. S. S., *6*, 1941, 27–29. [Rev. Appl. Myc., *19*, 1940, 268; *20*, 1941, 157, 396; *22*, 1943, 59].

4. **Fractilinea quarta** (Holmes) *comb. nov.* (*Marmor quartum* Holmes, *loc. cit.*, 65.) From Latin *quartus*, fourth.

Common name: Sugar-cane chlorotic-streak virus or fourth-disease virus.

Host: *GRAMINEAE—Saccharum officinarum* L., sugar cane.

Geographical distribution: Java, Queensland, Hawaii, Puerto Rico, Colombia, United States (Louisiana).

Induced disease: In sugar cane, reduction of growth rate; wilting at midday; long, narrow, longitudinal streaks, of creamy or white color, in the leaves. Streaks 1/16 to 3/16 inches wide, generally less than 1 foot long, fragmenting.

Transmission: By leafhopper, *Draeculacephala portola* Ball (*CICADELLIDAE*). Not demonstrated by inoculation of expressed juice.

Thermal inactivation: In cuttings, at 52° C in less than 20 minutes.

Literature: Abbott, Phytopath., *28*, 1938, 855–857; Sugar Bull., *16*, 1938, 3–4; Abbott and Ingram, Phytopath., *32*, 1942, 99–100; Bell, Queensland Agr. Jour., *40*, 1933, 460–464; Martin, Hawaiian Planters' Rec., *34*, 1930, 375–378; Hawaiian Sugar Planters' Assoc. Proc., *53*, 1934, 24–35.

5. **Fractilinea zeae** (Holmes) *comb. nov.* (*Marmor zeae* Holmes, *loc. cit.*, 59.) From New Latin *Zea*, generic name for corn (maize), from Latin *zea*, a kind of grain.

Common name: Maize-stripe virus.

Host: *GRAMINEAE—Zea mays* L., corn (maize).

Insusceptible species: *GRAMINEAE —Saccharum officinarum* L., sugar cane.

Geographical distribution: Hawaii, Tanganyika, Mauritius, Trinidad, Cuba. Not in United States.

Induced disease: In corn (maize), at first few, elongated, chlorotic lesions near base of young leaf, later enlarging and fusing to form continuous stripes. Subsequently formed leaves banded and striped variously. Vacuolate intracellular inclusions in cells of affected areas.

Transmission: By leafhopper, *Peregrinus maidis* (Ashm.) (*FULGORIDAE*); the incubation period in this in-

sect is usually between 11 and 29 days, although shorter periods have been demonstrated in a few cases. Virus may persist in the insect host until death, but may become exhausted earlier. Not by aphid, *Aphis maidis* Fitch (*APHIDIDAE*). Not by inoculation of expressed juice.

Literature: Briton-Jones, Trop. Agr., *10*, 1933, 119–122; Carter, Ann. Ent. Soc. Am., *34*, 1941, 551–556; Kunkel, Bull. Hawaiian Sugar Planters' Assoc., Bot. Ser., *3*, 1921, 44–57; 1924, 108–114; Hawaiian Planters' Rec., *26*, 1922, 58-64; Phytopath., *17*, 1927, 41 (Abst.); Stahl, Trop. Pl. Res. Found., Bull. 7, 1927; Storey, Rept. of Plant Pathologist, Amani Agr. Res. Station, 4th Ann. Rept., 1931-32, pp. 8–13.

6. **Fractilinea avenae** McKinney. (Jour. Washington Acad. Sci., *34*, 1944, 327.) From Latin *avena*, oats.

Common name: Pupation-disease virus.

Hosts: *GRAMINEAE*—*Avena sativa* L., oat; *Triticum aestivum* L., wheat; *Echinochloa crusgalli* Beauv.; *Setaria viridis*; rarely, *Agropyron repens* (L.) Beauv. and *Bromus inermis* Leyss. Experimentally, also *Hordeum vulgare* L., barley; *Panicum miliaceum* L., millet; *Oryza sativa* L., rice; *Secale cereale* L., rye; *Zea mays* L., corn (maize).

Geographical distribution: West Siberia.

Induced disease: In oat, chlorotic mottling, profuse development of shoots, proliferation of flowers with change to leaf-like structures. Protein crystals in affected cells have been regarded as accumulated virus.

Transmission: By leafhopper, *Delphax striatella* Fallan (*FULGORIDAE*), especially first and second instar nymphs; fifth instar nearly immune to infection. Incubation period, 6 days or more. Virus overwinters in insect as well as in plants. Not transmitted from an infected leafhopper to its progeny. Not through soil. Not through seeds from infected plants.

Literature: Sukhov et al., Compt. rend. Acad. Sci., U. R. S. S., *20*, 1938, 745–748; *26*, 1940, 479–482, 483–486.

FAMILY II. MARMORACEAE HOLMES EMEND.

(Handb. Phytopath. Viruses, 1939, 16.)

Viruses of the Mosaic Group, inducing diseases usually characterized by persistent chlorotic or necrotic spotting, and often by mottling. The family is here extended to include several small groups of viruses, formerly assigned independent family rank, but sharing a tendency to aphid transmission, so far as known, and inducing diseases characterized by abnormal growth habit, thickening and rolling of leaves, or dwarfing, traits not incompatible with the characters of the present group. Should any one of these small groups become the center of a large assemblage of new viruses in the future, separate familial status for it might again be advantageous. In the combined grouping here used, specific vectors, so far as known, are aphids (*APHIDIDAE*).

Key to the genera of family **Marmoraceae.**

I. Viruses of the Typical Mosaic-Disease Group.
 Genus I. *Marmor*, p. 1163.
II. Viruses of the Spindle-Tuber Group.
 Genus II. *Acrogenus*, p. 1202.
III. Viruses of the Leaf-Roll Group.
 Genus III. *Corium*, p. 1203.
IV. Viruses of the Dwarf-Disease Group.
 Genus IV. *Nanus*, p. 1206.
V. Viruses of the Rough-Bark Group.
 Genus V. *Rimocortius*, p. 1208.
VI. Viruses of the Symptomless Group.
 Genus VI. *Adelonosus*, p. 1211.

Genus I. **Marmor** *Holmes.*

(*Loc. cit.*, 16)

Viruses inducing typical mosaic diseases in various plants. Generic name from Latin *marmor*, a mottled substance.

The type species is *Marmor tabaci* Holmes.

Key to the groups within genus **Marmor.**

A. Relatively resistant to heat inactivation, usually requiring more than 10 minutes at 85 to 90° C for complete inactivation.
 1. Tobacco-Mosaic Virus Group.
B. Relatively susceptible to heat inactivation, requiring less than 10 minutes at 85 to 90° C for complete inactivation.
 a. Replacing potato-veinbanding virus in mixed infections.
  2. Tobacco-Etch Virus Group.
 aa. Not replacing potato-veinbanding virus in mixed infections.
  3. Cucumber-Mosaic Virus Group.
C. Many additional species cannot yet be grouped into definite subdivisions of the genus; they constitute a residual or
 4. Miscellaneous Mosaic-Virus Group.

Key to the species of the Tobacco-Mosaic Virus Group.

Viruses relatively resistant to heat inactivation, requiring in most cases more than 10 minutes at 85 to 90° C for complete inactivation. Insect vectors as yet unknown under natural conditions.

I. Found in nature principally in solanaceous plants; *Cucurbitaceae* insusceptible. Chlorotic mottling in some hosts, necrotic lesions in others as result of experimental infection. Suspensions show anisotropy of flow.
1. *Marmor tabaci.*
2. *Marmor constans.*

II. Found in nature only in cucurbitaceous plants; *Solanaceae* insusceptible. Only mottling as result of experimental infection. Suspensions show marked anisotropy of flow.
3. *Marmor astrictum.*

III. Found only in leguminous plants. Chlorotic lesions in some varieties of the common snap-bean plant, necrotic lesions in others, as a result of experimental infection.
4. *Marmor laesiofaciens.*

IV. Found in greenhouses confined to roots and lower parts of plants. Only necrotic lesions as result of experimental infection. Suspensions do not show anisotropy of flow.
5. *Marmor lethale.*

V. Found in tomato and experimentally transmissible to a number of species of plants in this and other families. Resembling the preceding in a number of physical characteristics, including failure to show anisotropy of flow.
5a. *Marmor dodecahedron.*

1. **Marmor tabaci** Holmes. (Holmes, Handb. Phytopath. Viruses, 1939, 17; *Musivum tabaci* Valleau, Phytopath., *30*, 1940, 822; *Phytovirus nicomosaicum* Thornberry, Phytopath., *31*, 1941, 23.) From New Latin *Tabacum*, early generic name for tobacco.

Common names: Tobacco-mosaic virus, tomato-mosaic virus.

Hosts: *SOLANACEAE—Nicotiana tabacum* L., tobacco; *Lycopersicon esculentum* Mill., tomato; and *Capsicum frutescens* L., garden pepper, among crop plants; nearly all, if not all, solanaceous plants can be infected, although in some the virus remains localized at or near the site of inoculation. *PLANTAGINACEAE*—A strain of this virus has been found in nature infecting *Plantago lanceolata* L., ribgrass, *P. major* L. and *P. rugelii* Dcne., common broad-leaved plantains. Experimental hosts are widely distributed through many related families of plants.

Geographical distribution: World-wide.

Induced disease: In most varieties of tobacco, yellowish-green primary lesions, followed by clearing of veins, distortion and greenish-yellow mottling of newly formed leaves. In Ambalema tobacco, no symptoms, virus being restricted to inoculated leaves or those nearby. Strains of tobacco showing necrotic effects have been produced recently. In tomato, no obvious primary lesions, systemic disease characterized by greenish-yellow mottling of foliage, moderate distortion of leaf shape, and a reduction of fruit yield not exceeding 50 per cent. If some strain of potato-mottle virus (*Marmor dubium*) is also present, a more severe disease is induced; this is known as double-virus streak, and is characterized by systemic necrosis. In most varieties of garden pepper, yellowish primary lesions followed by systemic chlorotic mottling. In the Tabasco pepper and its recent derivatives, recovery by abscission of inoculated leaf, after localization of virus in necrotic primary lesions. Vacuolate intracellular inclusions are found in chlorotic tissues of all hosts that show distinct chlorotic mottling.

Transmission: By slight abrasive contacts. By inoculation of expressed juice. To some extent by the aphids, *Myzus pseudosolani* Theob., *M. circumflexus* (Buckt.), *Macrosiphum solanifolii* Ashm., and *Myzus persicae* (Sulz.) (*APHIDIDAE*). By grafting. Through soil.

Through dodder, *Cuscuta campestris* Yuncker (*CONVOLVULACEAE*), without infecting this plant vector. Not through pollen from diseased plants. Not through seeds from diseased tobacco; seed transmission has been reported in the case of recently ripened seeds from diseased tomato.

Serological relationships: Precipitin test gives cross reactions between all known strains, except those characterized by failure to spread systemically in tobacco. No cross reactions with other viruses except weakly with cucurbit-mosaic virus (*Marmor astrictum*). Type and other strains of tobacco-mosaic virus give cross reactions in complement-fixation and neutralization tests.

Immunological relationships: Plant protection tests, particularly in *Nicotiana sylvestris* Spegaz. and Comes, have demonstrated that tissues invaded by any strain of this virus are immune to subsequent infection by the tomato aucuba-mosaic strain of tobacco-mosaic virus, indicating a group relationship not shared by other viruses, such as cucumber-mosaic virus or tobacco-ringspot virus.

Thermal inactivation: At 88 to 93° C in 10 minutes; at 86 to 92° C in 30 minutes.

Filterability: Tobacco-mosaic virus was the first virus shown to be filterable, by Iwanowski in 1892; its filterability was confirmed and interpreted by Beijerinck in 1898.

Other properties: The ultimate particles of tobacco-mosaic virus have been shown to be rod-shaped and isotropic, sometimes associated in pairs, end to end. Under proper conditions, thread-like paracrystals are formed. Specific gravity has been determined as about 1.37, refractive index as about 1.6. Isoelectric point between pH 3.2 and 3.5. Suspensions in media of lower refractive indices show anisotropy of flow. Sedimentation constants, at 20° C, 187×10^{-13} cm per sec. per dyne at infinite dilution for unaggregated virus and 216×10^{-13} cm per sec. per dyne for associated particles. The computed average length of the virus unit is about 272 millimicrons; diameter, 13.8 millimicrons. Electron micrographs show that characteristic particles are rod-like, between 10 and 20 millimicrons in width, variable in length, but in some preparations averaging 270 millimicrons in length for single units, 405 to 540 millimicrons in length for associated pairs; X-ray measurements in air-dry gel show width 15.20 ± 0.05 millimicrons. Solutions stronger than about 1.3 per cent separate into layers, the lower spontaneously doubly refracting and more concentrated than the upper. At concentrations of electrolytes somewhat less than are required to precipitate the virus as fibres or needle-shaped paracrystals, the solutions form clear gels that become fluid on shaking or diluting (at pH 7 and 30° C). The virus is destroyed by high-frequency sound radiation, by pressures between 6000 and 8000 kilograms per square centimeter, and by hydrogen-ion concentrations above pH 11 or below pH 1. It is relatively stable between pH 2 and pH 8. It is rapidly broken down in 6 M urea solutions, in the presence of salts, to low-molecular-weight components devoid of activity. Analysis of purified virus: carbon 47.7 per cent, hydrogen 7.35 per cent, nitrogen 15.9 per cent, sulfur 0.24 per cent, phosphorus 0.60 per cent, lipoid 0.0 per cent, carbohydrate 1.6 to 2.0 per cent. A revised estimate of the sulfur content is 0.20 per cent, probably all in cysteine; no methionine has been detected in the typical variety of this virus. The percentages of the following substances in the virus are: tyrosine 3.9, tryptophane 4.5, proline 4.6, arginine 9.0, phenylalanine 6.0, serine 6.4, threonine 5.3, cysteine 0.68, alanine 2.4, aspartic acid 2.6, glutamic acid 5.3, leucine 6.1, valine 3.9, nucleic acid 5.8, and amide nitrogen 1.9, collectively accounting for about 68 per cent of the total weight. Virus formation ceases in infected host tissues immersed in 0.0002 molar sodium cyanide solution, beginning again after removal of cyanide.

Literature: The literature dealing with tobacco-mosaic virus is too voluminous to permit citation of more than a few representative publications. Allard, U. S. Dept. Agr., Bull. 40, 1914; Bawden and Pirie, Proc. Roy. Soc. London, Ser. B., *123*, 1937, 274–320; Beale, Jour. Exp. Med., *54*, 1931, 463–473; Beijerinck, Verhandel. Konink. Akad. Wetenschappen te Amsterdam, II, *6*, 1898, 3–22; Grant, Phytopath., *24*, 1934, 311–336; Hoggan, Jour. Agr. Res., *49*, 1934, 1135–1142; Iwanowski, Bull. Acad. Imp. Sci. St. Petersburg, Ser. 4, *3*, 1892, 67–70; Jensen, Phytopath., 23, 1933, 964–974; Johnson, Science, 64, 1926, 210; Kausche et al., Naturwiss., *27*, 1939, 292–299; Knight, Jour. Biol. Chem., *147*, 1943, 663–666; Kunkel, Phytopath., *24*, 1934, 437–466; Lauffer, Jour. Am. Chem. Soc., *66*, 1944, 1188–1194; Price, Phytopath., *23*, 1933, 749–769; Stanley, Phytopath., *26*, 1936, 305–320; Takahashi and Rawlins, Proc. Soc. Exp. Biol. and Med., *30*, 1932, 155–157; Valleau and Johnson, Kentucky Agr. Exp. Sta., Bull. 376, 1937; Vinson, Science, *66*, 1927, 357–358; Woods, Science, *91*, 1940, 295–296.

Strains: A great number of variant strains have been isolated both experimentally and from plants infected in nature. These usually share with the type variety most of the fundamental properties, particle size, especially width, stability at relatively high temperatures, longevity in storage, some common antigens. The following have been distinguished from the type, var. *vulgare* H. (*loc. cit.*, 17), by varietal names:

1a. *Marmor tabaci* var. *aucuba* H. (*loc. cit.*, 20). A group of isolates producing necrotic local lesions in inoculated leaves of *Nicotiana sylvestris* Spegaz. and Comes; useful in identifying many other strains of this virus which on prior application protect the tissues of this plant from the necrotic effects of aucuba-type strains (Smith, Ann. Appl. Biol., *18*, 1931, 471–493; Kunkel, Phytopath., *24*, 1934, 437–466).

1b. *Marmor tabaci* var. *deformans* H. (*loc. cit.*, 22). Producing exceptionally severe malformation of tomato foliage. (Ainsworth, Ann. Appl. Biol., *24*, 1937, 545–556).

1c. *Marmor tabaci* var. *canadense* H. (*loc. cit.*, 23). Producing a necrotic type of streak disease in tomatoes (Jarrett, Ann. Appl. Biol., *17*, 1930, 248–259).

1d. *Marmor tabaci* var. *lethale* H. (*loc. cit.*, 24). Producing spreading necrotic lesions in tobacco and tomato under experimental conditions (Jensen, Phytopath., *27*, 1937, 69–84; Norval, Phytopath. *28*, 1938, 675–692).

1e. *Marmor tabaci* var. *plantaginis* H. (Phytopath., *31*, 1941, 1097). Specially adapted in nature for systemic spread in species of *Plantago*. This variety contains histidine (0.55 per cent) and methionine (2 per cent) not found in the type of the species.

1f. *Marmor tabaci* var. *obscurum* H. (Handb. Phytopath. Viruses, 1939, 25). Systemic in tobacco without producing obvious disease under experimental conditions (Holmes, Phytopath., *24*, 1934, 845–873; *26*, 1936, 896–904; Jensen, Phytopath., *27*, 1937, 69–84).

1g. *Marmor tabaci* var. *immobile* H. (*loc. cit.*, 26). Produces chlorotic primary lesions in experimentally infected tobacco, but rarely becomes systemic. (Jensen, Phytopath., *23*, 1933, 964–977; *27*, 1937, 69–84).

1h. *Marmor tabaci* var. *artum* H. (*loc. cit.*, 27). Necrotic lesions experimentally induced in *Nicotiana glutinosa* L. (*SOLANACEAE*) are much smaller than those of the type variety (Jensen, Phytopath., *27*, 1937, 69–84).

1i. *Marmor tabaci* var. *siccans* Doolittle and Beecher. (Phytopath., *32*, 1942, 991). Causing necrosis and shriveling of tomato foliage.

2. **Marmor constans** McKinney. (Jour. Washington Acad. Sci., *34*, 1944, 326.) From Latin *constans*, fixed.

Common name: Tobacco mild dark-green mosaic virus.

Hosts: *SOLANACEAE—Nicotiana glauca* R. Grah., tree tobacco.

Insusceptible species: *SOLANACEAE—Lycopersicon esculentum* Mill., tomato. *CUCURBITACEAE—Cucumis sativus* L., cucumber.

Geographical distribution: Islands of Grand Canary and Teneriffe.

Induced disease: In *Nicotiana glauca*, systemic chlorotic mottling.

Transmission: By inoculation of expressed juice. No insect vector is known.

Thermal inactivation: At about 86°C. in 10 minutes.

Literature: McKinney, Jour. Agr. Res., *39*, 1929, 557–578; Am. Jour. Bot., *28*, 1941, 770–778; Peterson and McKinney, Phytopath., *28*, 1938, 329–342; Thornberry and McKinney, *ibid.*, *29*, 1939, 250–260.

3. **Marmor astrictum** Holmes. (Holmes, Handb. Phytopath. Viruses, 1939, 27; *Musivum astrictum* Valleau, Phytopath., *30*, 1940, 823.) From Latin *astrictus*, limited, in reference to host range.

Common names: Cucurbit-mosaic virus, English cucumber-mosaic virus.

Hosts: *CUCURBITACEAE—Cucumis sativus* L., cucumber; *C. anguria* L., gherkin; *C. melo* L., melon; *Citrullus vulgaris* Schrad., watermelon; only cucurbitaceous plants have appeared to be susceptible thus far.

Insusceptible species: All tested solanaceous species. *CUCURBITACEAE—Bryonia dioica* L.; *Cucurbita pepo* L., vegetable marrow. *LEGUMINOSAE—Phaseolus vulgaris* L. var. Golden Cluster.

Geographical distribution: England.

Induced disease: In cucumber, clearing of veins and crumpling in young leaves, followed by a green-mosaic mottling, with blistering and distortion of newly formed leaves. Plant stunted. Fruit unmarked or slightly mottled. Diseased plants less obviously affected during winter months.

Transmission: By inoculation of expressed juice. No insect vector is known.

Serological relationships: Weak cross-precipitin reactions and full cross-neutralization reactions with tobacco-mosaic virus (*Marmor tabaci*). Two common antigens postulated. Preparations of virus that have been inactivated by treatment with nitrous acid or X-rays are still antigenic.

Thermal inactivation: At 80 to 90° C in 10 minutes.

Filterability: Passes Pasteur-Chamberland filters L_1 to L_7, and membranes of 150 millimicrons average pore diameter.

Other properties: Virus, infectious in dilution of 10^{-10}, is present to the extent of 0.2 to 0.3 gram per liter of juice from diseased plants. Preparations show sheen and anisotropy of flow, indicating rod-shaped particles. Solutions stronger than 2.5 per cent separate into 2 layers at room temperature, the lower being the more concentrated and birefringent. Precipitates with ammonium sulfate show needle-shaped paracrystals. Sedimentation constants $S_{20}° = 173 \times 10^{-13}$ cm. sec.$^{-1}$ dyne^{-1} and about 200×10^{-13} cm. sec.$^{-1}$ dyne^{-1}. Virus withstands drying without inactivation but with partial loss of ability to show anisotropy of flow and with reduction of serological activity to about half. Tryptophane content 1.4 per cent, phenylalanine 10.2 per cent, the first lower and the second higher than in tobacco-mosaic virus.

Literature: Ainsworth, Ann. Appl. Biol., *22*, 1935, 55–67; Bawden and Pirie, Nature, *139*, 1937, 546–547; Brit. Jour. Exp. Path., *18*, 1937, 275–291; Knight, Arch. Virusf., *2*, 1942, 260–267; Knight and Stanley, Jour. Biol. Chem., *141*, 1941, 29–38; *141*, 1941, 39–49; Price, Am. Jour. Bot., *27*, 1940, 530–541; Price and Wyckoff, Nature, *141*, 1938, 685.

Strains: A distinctive strain has been distinguished from the type, var. *chlorogenus* H. (*loc. cit.*, 27), by the varietal name:

3a. *Marmor astrictum* var. *aucuba* H. (*loc. cit.*, 29). Differing from the type of this species by inducing a yellow-mottling, rather than a green-mottling, mosaic in cucumber (Ainsworth, Ann. Appl. Biol., *22*, 1935, 55–67).

4. **Marmor laesiofaciens** Zaumeyer and Harter. (Jour. Agr. Res., *67*, 1943, 305.) From Latin *laesio*, substantive from *laedere*, to injure, and participle from *facere*, to make.

Common name: Bean-mosaic virus 4; southern bean mosaic virus 1.

Hosts: *LEGUMINOSAE—Phaseolus vulgaris* L., bean. Experimentally, also *Phaseolus lunatus* L., sieva bean; *Soja max* Piper var. Virginia, Virginia soy bean.

Insusceptible species: All tested species in families other than the *LEGUMINOSAE*.

Geographical distribution: United States (Louisiana).

Induced disease: In bean, systemic chlorotic mottling in some varieties, localized necrosis in others; in a few varieties, systemic necrosis. In mottling-type varieties, chlorotic mottling of foliage; pods marked by dark green blotches or shiny areas, slightly malformed, short, frequently curled at end. In necrotic-type varieties with localized response, bearing a dominant gene lacking in mottling-type varieties, reddish necrotic lesions at the site of inoculation; no evidence of systemic spread of virus. In varieties showing systemic necrosis, pinpoint or slightly larger necrotic primary lesions with veinal necrosis of inoculated leaf; systemic veinal necrosis, distortion and curling of affected leaves, drooping at the pulvini; stem and petiole streak; eventual death of plant.

Transmission: By inoculation of expressed juice. Through seeds from infected plants.

Serological relationships: Not demonstrated.

Immunological relationships: Previous infection with bean-mosaic virus, *Marmor phaseoli*, does not protect against infection with this virus.

Thermal inactivation: At 90 to 95° C, time not stated, probably 10 minutes.

Other properties: Withstands dilution of 1:500,000 and aging 32 weeks at 18° C.

Literature: Zaumeyer and Harter, Phytopath., *32*, 1942, 438–439; *33*, 1943, 16; *34*, 1944, 510–512; Jour. Agr. Res., *67*, 1943, 295–300, 305–328.

Strains: A strain differing from the type has been given the varietal name:

4a. *Marmor laesiofaciens* var. *minus* Zaumeyer and Harter. (Jour. Agr. Res., *67*, 1943, 305.) From Latin *minor*, lesser. Differing from the type by inducing formation of slightly less diffuse and spreading lesions in necrotic-type bean leaves; also by inducing milder early symptoms and more severe late symptoms in mottling-type beans. Passes through seeds from infected plants to infect seedlings grown from them. Found in additional localities in the United States (California, Colorado, Idaho, Maryland).

5. **Marmor lethale** H. (*loc. cit.*, 86). From Latin *lethalis*, causing death.

Common name: Tobacco-necrosis virus.

Hosts: *SOLANACEAE—Nicotiana tabacum* L., tobacco; *N. glutinosa* L.; *N. langsdorffii* Weinm.; *Lycopersicon esculentum* Mill., tomato; *Solanum nigrum* L. *COMPOSITAE*—Aster. *GERANIACEAE—Pelargonium hortorum* Bailey. *LEGUMINOSAE—Phaseolus vulgaris* L., bean. Confined to roots of these natural hosts except in the cases of *Nicotiana tabacum* and *N. glutinosa* in which lower leaves are sometimes invaded; necrotic lesions along midrib and larger veins in these. No obvious manifestations of disease in infected roots. Experimentally to plants in many families with production of localized necrotic lesions only.

Geographical distribution: England, Scotland, Australia. This virus has been found only in greenhouses.

Induced disease: In tobacco, necrosis of midrib and larger veins of first-developed pair of leaves, between November and February. Virus also in roots of many healthy-looking plants throughout the year. Upon artificial inoculation of foliage, numerous small brown necrotic local lesions are produced. Yield of virus from infected plant 0.02 mg per cc of expressed juice, on the average.

Transmission: By contamination of soil with virus. No insect vector is known. Experimentally, by inoculation of expressed juice.

Serological reactions: Precipitates with homologous antiserum. No cross reaction with tomato bushy-stunt or tobacco-mosaic viruses.

Immunological relationships: Protection tests show lack of relationship to tobacco-mosaic virus, tobacco-ringspot virus, tomato-ringspot virus, cucumber-mosaic virus, and the severe-etch strain of tobacco-etch virus.

Thermal inactivation: At 90 to 92° C in 10 minutes.

Filterability: Average particle diameter 20 to 30 millimicrons as determined by filtration through Gradocol membranes; other reports give diameter as 13 to 20 millimicrons by filtration (14 to 19 millimicrons by radiation experiments, about 20 millimicrons from electron micrographs).

Other properties: Infectious after storage for months in dried leaves and after storage for half a year in absolute ethyl alcohol at room temperature. Specific gravity 1.3. More soluble in ammonium sulfate solutions at 0° C than at room temperature. Composition: Carbon 44.8 to 45.3 per cent, nitrogen 15.5 to 16.5 per cent, hydrogen 6.5 to 7.0 per cent, phosphorus 1.4 to 1.7 per cent, sulfur 1.1 to 2.0 per cent, carbohydrate 7.0 to 9.0 per cent; ash 5.8 to 7.0 per cent (3 to 5 per cent after prolonged dialysis at pH 3). Nucleic acid of the ribose type has been isolated. No anisotropy of flow in solution but crystals are birefringent, showing sharp extinctions parallel to, and at right angles to, the plane of the crystal when examined edge-on in a polarizing microscope. Sedimentation constant, $S_{20}° = 112 \times 10^{-13}$; in other preparations a crystalline component with sedimentation constant 130×10^{-13} and an amorphous component with sedimentation constant 58×10^{-13} have been reported, as well as small amounts of a substance with sedimentation constant 220×10^{-13}.

Strains: Isolates of tobacco-necrosis virus serologically distinct but not otherwise different from each other appear to imply the existence of several strains of this virus, or of a closely related group of viruses, in England.

Literature: Bawden, Brit. Jour. Exp. Path., *22*, 1941, 59–70; Bawden et al., *ibid.*, *23*, 1942, 314–328; Cohen, Proc. Soc. Exp. Biol. and Med., *48*, 1941, 163–167; Lea, Nature, *146*, 1940, 137–138; Pirie et al., Parasitol., *30*, 1938, 543–551; Price, Am. Jour. Bot., *25*, 1938, 603–612; Am. Jour. Bot., *27*, 1940, 530–541; Arch. Virusf., *1*, 1940, 373–386; Price and Wyckoff, Phytopath., *29*, 1939, 83–94; Smith, Parasitol., *29*, 1937, 70–85; *29*, 1937, 86–95; Smith and Bald, Parasitol., *27*, 1935, 231–245; Smith and MacClement, Parasitol., *32*, 1940, 320–332.

5a. **Marmor dodecahedron** H. (*loc. cit.*, 30). From Greek *dōdekahedron*, dodecahedron.

Common name: Tomato bushy-stunt virus.

Hosts: *SOLANACEAE—Lycopersicon esculentum* Mill., tomato. Experimentally, also *SOLANACEAE—Datura stramonium* L.; *Nicotiana glutinosa* L.; *N. langsdorffii* Weinm.; *N. tabacum* L., tobacco; *Solanum nigrum* L. *LEGUMINOSAE—Phaseolus vulgaris* L., bean; *Vigna sinensis* (L.) Endl., cowpea. *COMPOSITAE—Zinnia elegans* Jacq., zinnia.

Geographical distribution: British Isles.

Induced disease: In tomato, some primary lesions necrotic, ring-like or spot-like, others masked, or disclosed only by chlorophyll retention in yellowing leaves. In young plants, systemic necrotic lesions may cause death; in older plants, growth ceases, young leaves become pale yellow; growing points may die, inducing growth of axillary buds to produce a bushy top; older leaves become yellowed and show some purple coloration. In White Burley tobacco, local necrosis only, lesions small, red at first, then white. In cowpea, reddish necrotic primary lesions only.

Transmission: By inoculation of expressed juice. Through dodder, *Cuscuta campestris* Yuncker (*CONVOLVULACEAE*). Not through seeds of diseased plants. No insect vector is known.

Serological relationships: A specific antiserum, prepared by a single intravenous injection of rabbits with 2 mg of purified virus, gives granular, compact precipitates, serving for quantitative estimation of this virus, antiserum being used at dilutions of 1:200 or 1:800, virus at dilutions to 10^{-6}.

Immunolcgical relationships: Will infect plants previously invaded by tobacco-mosaic virus, tomato spotted-wilt virus, tobacco-ringspot virus, and Bergerac-ringspot virus.

Filterability: Passes membranes down to 40 millimicrons average pore diameter.

Other properties: Virus crystallizes from solutions of ammonium sulfate as isotropic, rhombic dodecahedra, which shrink and swell reversibly on drying and rewetting; shrinkage reduces size to 80 per cent of the wet dimensions. In the presence of heparin, non-birefringent prisms, rather than dodecahedra, appear. $S_{20}° = 132 \times 10^{-13}$ cm. sec.$^{-1}$ dyne^{-1}. Particle approximately spherical, 27.4 millimicrons in diameter by X-ray measurements (average diameter by filtration data, 14 to 20 millimicrons). Solutions do not show anisotropy of flow. Inactivated by drying. Molecular weight 8,800,000. Density 1.353. Molecular weight may be as high as 24,000,000 in solution, but the density is then lower, 1.286. Analysis: carbon 47 to 50 per cent, nitrogen 15.8 to 16.4 per cent, phosphorus 1.3 to 1.5 per cent, ash 1.7 to 5 per cent, hydrogen 7.2 to 8.2 per cent, sulfur 0.4 to 0.8 per cent, carbohydrate 5 to 6 per cent.

Literature: Ainsworth, Jour. Ministry Agr., *43*, 1936, 266–269; Bawden and Pirie, Nature, *141*, 1938, 513; Brit. Jour. Exp. Path., *19*, 1938, 251–263; Bernal and Fankuchen, Jour. Gen. Physiol., *25*, 1941, 111–165; Bernal et al., Nature, *142*, 1938, 1075; Cohen, Jour. Biol. Chem. *144*, 1942, 353–362; Proc. Soc. Exp. Biol. and Med., *51*, 1942, 104–105; Lauffer, Jour. Phys. Chem., *44*, 1940, 1137–1146; Lauffer and Stanley, Jour. Biol. Chem., *135*, 1940, 463–472; Neurath and Cooper, Jour. Biol. Chem., *135*, 1940, 455–462; Smith, Nature, *135*, 1935, 908; Ann. Appl. Biol., *22*, 1935, 731–741; Jour. Roy. Hort. Soc., *60*, 1935, 448–451; Smith and MacClement, Parasitol., *33*, 1941, 320–330; Stanley, Jour. Biol. Chem., *135*, 1940, 437–454.

Key to the species of the Tobacco-Etch Virus Group.

Viruses relatively susceptible to heat inactivation (inactivated at 52 to 58° C in 10 minutes). A small, closely allied group, tending to replace or to be replaced by each other, if present in mixture in tobacco.

I. Not replaced, if in mixture, by other viruses of this group; dominant member of the group in tobacco.
   6. *Marmor erodens.*

II. Replaced by No. 6, not by No. 8, if in mixture with it in tobacco.
   7. *Marmor hyoscyami.*

III. Replaced by No. 6 or 7 if in mixture with either in tobacco.
   8. *Marmor upsilon.*

6. **Marmor erodens** Holmes. (Holmes, Handb. Phytopath. Viruses, 1939, 40; *Foliopellis erodens* Valleau, Phytopath., *30*, 1940, 825.) From Latin *erodere*, to erode or gnaw away.

Common name: Tobacco-etch virus.

Hosts: *SOLANACEAE—Capsicum frutescens* L., pepper; *Datura stramonium* L., Jimson weed; *Lycopersicon esculentum* Mill., tomato; *Nicotiana tabacum* L., tobacco; *Petunia* sp., petunia; *Physalis heterophylla* Nees.

Geographical distribution: United States.

Induced disease: In tobacco, systemic mild-mottling chlorosis, with traces of necrotic etching; intranuclear crystalline inclusions and intracytoplasmic granular and amorphous inclusions that tend to crystallize, forming needle-shaped birefringent bodies, 2 to 10 microns in length.

Transmission: Experimentally, by *Myzus persicae* (Sulz.), *M. circumflexus* (Buckt.), *Aphis rhamni* Boyer, *A. fabae* (Scop.), and *Macrosiphum gei* (Koch) (*APHIDIDAE*); by inoculation of expressed juice.

Serological relationships: Precipitin reactions with homologous antisera, but no cross-reactions with tobacco-mosaic virus, tobacco-ringspot virus, potato-mottle virus, potato aucuba-mosaic virus, potato mild-mosaic virus, hyoscyamus-mosaic virus, potato-veinbanding virus, or pea-mosaic virus.

Immunological relationships: Protects tobacco against subsequent infection by potato-veinbanding virus and hyoscyamus-mosaic virus. In mixed infections, it suppresses and replaces these two viruses.

Thermal inactivation: At 53 to 55° C in 10 minutes.

Filterability: Passes Pasteur-Chamberland L_1, not L_3, filter candle.

Other properties: Sedimentation constant $S_{20}° = 170 \times 10^{-13}$ cm. sec.$^{-1}$ dyne^{-1}. Concentrated preparations show anisotropy of flow, indicating elongated particle shape.

Literature: Bawden and Kassanis, Ann. Appl. Biol., *28*, 1941, 107–118; Fernow, Cornell Agr. Exp. Sta. (Ithaca), Mem. 96, 1925; Holmes, Phytopath., *32*, 1942, 1058–1067; Johnson, Kentucky Agr. Exp. Sta., Res. Bull. 306, 1930.

Strains: A distinctive severe-symptom strain, isolated from plants infected in nature and studied intensively, has been distinguished from the type, var. *vulgare* H. (*loc. cit.*, 40), by the varietal name:

6a. *Marmor erodens* var. *severum* H. (*loc. cit.*, 41). Differing from the type by a tendency to induce more pronounced necrotic etching and a greater stunting effect in infected tobacco.

7. **Marmor hyoscyami** *spec. nov.* From New Latin *Hyoscyamus*, genus name of plant from which this virus was first isolated.

Common names: Hyoscyamus-mosaic virus, Hy. III virus, Hyoscyamus-III-disease virus.

Hosts: *SOLANACEAE—Hyoscyamus niger* L., henbane. Experimentally, also *Nicotiana tabacum* L., tobacco.

Insusceptible species: *CUCURBITACEAE—Cucumis sativus* L., cucumber.

Geographical distribution: England.

Induced disease: In henbane, chlorotic clearing of veins followed by yellow-mottling mosaic.

Transmission: By inoculation of expressed juice to dilutions of 10^{-4}. By aphids, *Myzus persicae* (Sulz.), *M. circumflexus* (Buckt.), and *Macrosiphum solanifolii* Ashm. (= *M. gei* Koch) (*APHIDIDAE*).

Serological relationships: Several isolates of this virus give mutual cross-precipitin reactions but no precipitation occurs when antiserum prepared with this virus is mixed with cucumber-mosaic virus, tobacco-etch virus, or potato-veinbanding virus.

Immunological relationships: No immunity with respect to this virus is induced in tobacco by previous infection with cucumber-mosaic virus. Potato-veinbanding virus is unable to multiply in the presence of this virus and is replaced by it. Tobacco-etch virus pro-

tects against this virus and replaces it in mixed infections.

Thermal inactivation: At 58° C in 10 minutes.

Filterability: Passes Chamberland L_1, but not L_3, filter candles.

Other properties: Concentrated solutions show anisotropy of flow. Yield of virus, 1 to 3 mg per liter of juice expressed from diseased tobacco plants.

Literature: Bawden and Kassanis, Ann. Appl. Biol., *28*, 1941, 107–118; Hamilton, *ibid.*, *19*, 1932, 550–567; Sheffield, *ibid.*, *25*, 1938, 781–789; Watson and Roberts, Proc. Roy. Soc. London, Ser. B, *127*, 1939, 543–576.

8. **Marmor upsilon** *comb. nov.* (*Marmor cucumeris* var. *upsilon* Holmes, *loc. cit.*, 33; *Murialba venataenia* Valleau, Phytopath., *30*, 1940, 824.) From Greek name of the letter Y, sometimes used to denote this virus.

Common names: Potato-veinbanding virus, potato virus Y.

Hosts: *SOLANACEAE—Solanum tuberosum* L., potato; *Nicotiana tabacum* L., tobacco. Experimentally, also *Lycium barbarum* L.

Geographical distribution: England, France, United States, Brazil. Rare in Scotland and part of Ireland.

Induced disease: In some potato varieties, leaf drop and necrotic stem-streak; in others, no signs of disease; in still others, chlorotic mottling with or without necrosis. In combination with strains of the potato-mottle virus (*Marmor dubium*), this virus causes rugose mosaic, a common and destructive double-virus disease.

Transmission: By inoculation of expressed juice. By aphid, *Myzus persicae* (Sulz.); experimentally, also by *Aphis rhamni* Boyer (synonym for *Aphis abbreviata* Patch) (*APHIDIDAE*).

Serological relationships: Precipitin reactions with homologous antisera. No cross reactions with tobacco-mosaic virus, tobacco-etch virus, hyoscyamus-mosaic virus, potato-mottle virus, potato mild-mosaic virus, potato aucuba-mosaic virus, tobacco-ringspot virus, or common pea-mosaic virus. Reported cross reaction with cucumber-mosaic virus needs confirmation.

Immunological relationships: A mild strain protects against subsequent infection with the typical virus. This virus is suppressed and replaced by hyoscyamus-mosaic virus and by tobacco-etch virus in mixed infections.

Thermal inactivation: At 52° C in 10 minutes.

Filterability: Passes with difficulty through Gradocol membrane of 42 millimicron average pore diameter.

Other properties: Inactivated by drying.

Literature: Dennis, Nature, *142*, 1938, 154; Johnson, Phytopath., *25*, 1935, 650–652; Jones and Vincent, Jour. Agr. Res., *55*, 1937, 69–79; Kassanis, Ann. Appl. Biol., *29*, 1942, 95; Koch, Phytopath., *23*, 1933, 319–342; Kramer and Silberschmidt, Arquivos Inst. Biol., São Paulo, Brazil, *11*, 1940, 165–188; Salaman, Nature, *139*, 1937, 924; Smith, Proc. Roy. Soc., Ser. B, *109*, 1931, 251–267; Smith and Dennis, Ann. Appl. Biol., *27*, 1940, 65–70.

Key to the species of the Cucumber-Mosaic Virus Group.

Viruses relatively susceptible to heat inactivation, requiring less than 10 minutes at 85 to 90° C for complete inactivation. Not replacing potato-veinbanding virus in mixed infections.

I. Infecting both dicotyledonous and monocotyledonous plants.

9. *Marmor cucumeris.*

II. Infecting dicotyledonous, but not monocotyledonous, plants.

10. *Marmor solani.*

11. *Marmor aucuba.*

12. *Marmor umbelliferarum.*

13. *Marmor cruciferarum.*
14. *Marmor brassicae.*
15. *Marmor betae.*
16. *Marmor lactucae.*
17. *Marmor dahliae.*
18. *Marmor phaseoli.*
19. *Marmor leguminosarum.*
20. *Marmor pisi.*
21. *Marmor medicaginis.*

III. Infecting monocotyledonous, but not dicotyledonous, plants.

22. *Marmor tulipae.*
23. *Marmor mite.*
24. *Marmor iridis.*
25. *Marmor sacchari.*
26. *Marmor cepae.*
27. *Marmor scillearum.*

9. **Marmor cucumeris** Holmes. (Holmes, Handb. Phytopath. Viruses, 1939, 31; *Murialba cucumeris* Valleau, Phytopath., *30*, 1940, 823.) From Latin *cucumis*, cucumber.

Common name: Cucumber-mosaic virus.

Hosts: Very wide range of hosts among dicotyledonous and monocotyledonous plants; cucumber, celery, spinach, tobacco, and pepper are sometimes seriously affected. Overwintering hosts are: *SOLANACEAE—Physalis subglabrata* Mackenzie and Bush, *P. heterophylla* Nees. *ASCLEPIADACEAE—Asclepias syriaca* L. *PHYTOLACCACEAE—Phytolacca decandra* L. *LABIATAE—Nepeta cataria* L. Probably there are also other susceptible perennials.

Geographical distribution: Probably almost world-wide.

Induced disease: In cucumber, *Cucumis sativus* L., yellowish-green systemic mottling. Leaves small, distorted, curled; plants dwarfed, internodes shortened. Few fruits set. Fruits mottled, misshapen, giving the disease the name "white pickle." In black cowpea, *Vigna sinensis* (L.) Endl., small reddish necrotic local lesions only. No intracellular bodies are found in plants infected with cucumber-mosaic virus.

Transmission: By inoculation of expressed juice. By aphids, *Myzus persicae* (Sulz.), *M. pseudosolani* Theob., *M. circumflexus* (Buckt.), *Macrosiphum solanifolii* Ashm., and *Aphis gossypii* Glov. (*APHIDIDAE*). Through seeds of diseased plants in *Echinocystis lobata* (Michx.) Torr. and Gray, wild cucumber, in *Cucumis melo* L., muskmelon, and in *Cucurbita pepo* L., vegetable marrow. By several species of dodder, *Cuscuta californica* Choisy, *C. campestris* Yuncker, and *C. subinclusa* Dur. and Hilg. (*CONVOLVULACEAE*).

Immunological relationships: Infection with the type and other chlorotic-mottling strains protects zinnia against subsequent infection by an indicator strain of this virus (var. *judicis*).

Thermal inactivation: At 70 to 80° C in 10 minutes.

Filterability: Passes Berkefeld W and N filters and collodion membranes of 45 millimicron average pore diameter.

Other properties: Inactivated by drying or 3 to 4 days' storage in juice at room temperature.

Literature: Ainsworth, Ann. Appl. Biol., *25*, 1938, 867–869; Chamberlain, New Zealand Jour. Science and Technology, *21*, 1939, 73A–90A; Celino, Philippine Agr., *29*, 1940, 379–414; Doolittle, Phytopath., *6*, 1916, 145–147; U. S. Dept. Agr., Bull. 879, 1920; Doolittle and Walker, Jour. Agr. Res., *31*, 1925, 1–58; Gilbert, Phytopath., *6*, 1916, 143–144; Hoggan, Jour. Agr. Res., *47*, 1933, 689–704; Jagger, Phytopath., *6*, 1916, 148–151;

8, 1918, 32–33; Kendrick, Phytopath., *24*, 1934, 820–823; Mahoney, Proc. Am. Soc. Hort. Sci., *332*, 1935, 477–480; Price, Phytopath., *25*, 1935, 776–789; *29*, 1939, 903–905; Am. Jour. Bot., *27*, 1940, 530–541; Storey, Ann. Appl. Biol., *26*, 1939, 298–308.

Strains: Various host plants seem to have induced specialization of cucumber-mosaic virus in strains particularly adapted to existence in their tissues. Several of these and certain laboratory-derived strains useful in technical procedures have been distinguished from the type, var. *vulgare* H. (*loc. cit.*, 31), by varietal names, as follows:

9a. *Marmor cucumeris* var. *commelinae* H. (*loc. cit.*, 35). From New Latin *Commelina*, generic name of weed serving as a natural reservoir of this strain. Common name: Southern celery-mosaic strain of cucumber-mosaic virus. Differing from the type in severity of disease induced in celery and some other plants. Transmitted by *Aphis gossypii* Glov., *A. maidis* Fitch, and *Pentalonia nigronervosa* Coq. (*APHIDIDAE*). (Price, Phytopath., *25*, 1935, 947–954; Wellman, *ibid.*, *24*, 1934, 695–725, 1032–1037; *25*, 1935, 289–308, 377–404.)

9b. *Marmor cucumeris* var. *phaseoli* H. (*loc. cit.*, 36). From New Latin *Phaseolus*, generic designation of lima bean. Common name: Lima-bean strain of cucumber-mosaic virus. Differing from type of species in ability to cause a chlorotic mottling disease in lima bean in nature. (Harter, Phytopath., *26*, 1936, 94; Jour. Agr. Res., *56*, 1938, 895–906; McClintock, Phytopath., *7*, 1917, 60.)

9c. *Marmor cucumeris* var. *lilii* H. (*loc. cit.*, 37). From Latin *lilium*, lily. Common name: Lily-mosaic strain of cucumber-mosaic virus. Differing from the type variety by ability to persist in nature in lilies, producing masked infection or chlorotic mottling unless in mixture with lily-symptomless virus (*Adelonosus lilii*), when a more severe disease involving necrosis is induced. (Brierley, Phytopath., *29*, 1939, 3; *30*, 1940, 250–257; Brierley and Doolittle, *ibid.*, *30*, 1940, 171–174; Ogilvie and Guterman, *ibid.*, *19*, 1929, 311–315; Price, *ibid.*, *27*, 1937, 561–569.)

9d. *Marmor cucumeris* var. *judicis* H. (*loc. cit.*, 38). From Latin *judex*, judge. Common name: Indicator strain of cucumber-mosaic virus. Differing from the type variety in inducing the formation of necrotic local lesions in zinnia (*Zinnia elegans* Jacq., *COMPOSITAE*). Previous infection of zinnia by other strains of cucumber-mosaic virus inhibits the formation of these necrotic local lesions, identifying the strains as related to each other and to the indicator strain. (Price, Phytopath., *24*, 1934, 743–761; *25*, 1935, 776–789.)

9e. *Marmor cucumeris* var. *vignae* H. (*loc. cit.*, 39). From New Latin *Vigna*, generic name of cowpea. Common name: Cowpea-mottling strain of cucumber-mosaic virus. Differing from the type variety in producing systemic chlorotic mottling, rather than reddish-brown necrotic local lesions, in Black cowpea. Not known in nature but derived experimentally from a mild-mottling strain of cucumber-mosaic virus during serial passage in cowpea. (Price, Phytopath., *24*, 1934, 743–761; *25*, 1935, 776–789.)

10. **Marmor solani** H. (*loc. cit.*, 47). From New Latin *Solanum*, generic name of potato.

Common names: Potato mild-mosaic virus, potato virus A.

Hosts: *SOLANACEAE—Solanum tuberosum* L., potato. Experimentally, also *Nicotiana tabacum* L., tobacco; *Solanum nigrum* L. var. *nodiflorum*; and *Datura stramonium* L., Jimson weed.

Geographical distribution: United States, England, Holland.

Induced disease: In potato, very mild chlorotic mottling or masked symptoms in some varieties (as Irish Chieftain), systemic necrosis in others (for example,

British Queen). Immunity to aphid infection with this virus is found in the varieties Katahdin and Earlaine. A combination disease, characterized by pronounced yellow-mosaic patterns, is caused by this virus in the variety Irish Chieftain if the potato-veinbanding virus (*Marmor upsilon*) is also present. In tobacco, experimentally, faint veinbanding mosaic.

Transmission: To potato, by rubbing methods of inoculation of expressed juice, using carborundum powder; to tobacco, by rubbing without carborundum. By aphids, *Aphis abbreviata* Patch and *Myzus persicae* (Sulz.) (*APHIDIDAE*).

Serological relationships: No cross-precipitin reactions with potato aucuba-mosaic virus, potato-veinbanding virus, tobacco-mosaic virus, tobacco-etch virus, tobacco-ringspot virus, or pea-mosaic virus.

Immunological relationships: A feeble strain of this virus has been found to protect fully against the typical strain in the Netherlands.

Thermal inactivation: At 50° C in 10 minutes.

Literature: Bawden, Ann. Appl. Biol., *23*, 1936, 487–497; Chester, Phytopath., *25*, 1935, 686–701; Dykstra, Phytopath., *29*, 1939, 40–67; Hansen, Tidsskr. Planteavl, *42*, 1937, 631–681; Murphy and Loughnane, Sci. Proc. Roy. Dublin Soc., *21*, 1936, 419–430; Murphy and McKay, *ibid.*, *20*, 1932, 227–247; Oortwijn Botjes, Tijdsch. Plantenziekten, *45*, 1939, 25–29; Schultz *et al.*, Phytopath., *27*, 1937, 190–197; *30*, 1940, 944–951.

11. **Marmor aucuba** H. (*loc. cit.*, 49). From New Latin *Aucuba*, a genus of plants having mottled foliage.

Common name: Potato aucuba-mosaic virus.

Hosts: *SOLANACEAE—Solanum tuberosum* L., potato. Experimentally, also *Atropa belladonna* L. (symptomless); *Capsicum frutescens* L., pepper; *Datura stramonium* L., Jimson weed (symptomless); *Hyoscyamus niger* L., henbane (symptomless); *Lycopersicon esculentum* Mill., tomato; *Petunia hybrida* Vilm., *petunia* (symptomless); *Nicotiana tabacum* L., tobacco (symptomless); *Solanum dulcamara* L., bittersweet; *S. nigrum* L. var. *nodiflorum*.

Geographical distribution: United States, Great Britain, Europe.

Induced disease: In potato, yellow spots on lower leaves of some varieties; in the variety Irish Chieftain, brilliant yellow mottle over whole plant, perhaps because of simultaneous presence of potato mild-mosaic virus in this variety. Necrosis of the cortex and of the pith in tubers in many varieties.

Transmission: By inoculation of expressed juice. Probably by aphid, *Myzus persicae* (Sulz.) (*APHIDIDAE*).

Serological relationships: No precipitin cross-reactions with potato mild-mosaic virus, potato-veinbanding virus, tobacco-mosaic virus, tobacco-etch virus, tobacco-ringspot virus, or pea-mosaic virus. Precipitin cross-reactions with the Canada-streak strain of potato aucuba-mosaic virus.

Thermal inactivation: At 65 to 68° C in 10 minutes.

Filterability: Passes Pasteur-Chamberland L_1 filter, but not L_3 or L_5.

Literature: Chester, Phytopath., *25*, 1935, 686–701; *27*, 1937, 903–912; Clinch, Sci. Proc. Roy. Dublin Soc., *22*, 1941, 435–445; Clinch et al., *ibid.*, *21*, 1936, 431–448; Dykstra, Phytopath., *29*, 1939, 917–933.

Strains: One strain differing from the type has been given a varietal name:

11a. *Marmor aucuba* var. *canadense* Black and Price. (Phytopath. *30*, 1940, 444.) From common name of strain.

Common name: Canada-streak strain of potato aucuba-mosaic virus. Differing from the type variety by tendency to produce necrosis in stems, veins, petioles, and leaves and also, about 2 months after harvest, in pith of tuber, especially at stem end. (Chester, Phytopath., *27*,

1937, 903–912; Dykstra, Phytopath., *29*, 1939, 917–933.)

12. **Marmor umbelliferarum** H. (*loc. cit.*, 67). From New Latin *Umbelliferae*, family name of plants among which celery is classified.

Common name: Celery-mosaic virus, western celery-mosaic virus.

Hosts: *UMBELLIFERAE—Apium graveolens* L., celery and celeriac; *Daucus carota* L., carrot. Experimentally, also *Anethum graveolens* L., dill; *Anthriscus cerefolium* (L.) Hoffm., salad chervil; *Carum carvi* L., caraway; *Coriandrum sativum* L., coriander; *Petroselinum hortense* Hoffm., parsley.

Insusceptible species: *Cucumis sativus* L., cucumber, and all other tested species not of the family *Umbelliferae.*

Geographical distribution: United States (California).

Induced disease: In celery, at first, clearing of veins in young leaves; later, foliage yellowed, plant stunted, young petioles shortened, older petioles horizontal, giving plant a flat appearance. Foliage mottled green and yellow; leaflets narrow, twisted or cupped; older leaves with some necrosis; petioles with white streaks or spots. In celeriac, clearing of veins, followed by systemic chlorotic mottling. In carrot, chlorotic spotting of young leaves, followed by systemic chlorotic mottling.

Transmission: By inoculation of expressed juice, in dilutions to 1:4000. No specific insect vector is known, but 11 species of aphids capable of breeding on celery transmit the virus, though they do not long retain the power of transmission after leaving diseased plants. These vectors are *Aphis apigraveolens* Essig, *A. apii* Theob., *A. ferruginea-striata* Essig, *A. gossypii* Glov., *A. middletonii* Thomas, *A. rumicis* Linn., *Cavariella capreae* (Fabr.), *Myzus circumflexus* (Buckt.), *M. convolvuli* (Kalt.), *M. persicae* (Sulz.), *Rhopalosiphum melliferum* (Hottes) (*APHIDIDAE*). Some aphids not able to breed on celery also transmit this virus.

Thermal inactivation: At 55 to 60° C in 10 minutes.

Filterability: Passes all grades of Chamberland filters.

Other properties: Virus active after storage at −18° C for 18 months.

Literature: Severin and Freitag, Hilgardia, *11*, 1938, 493–558.

13. **Marmor cruciferarum** H. (*loc. cit.*, 69). From New Latin *Cruciferae*, family name of plants among which cauliflower is classified.

Common name: Cauliflower-mosaic virus.

Hosts: *CRUCIFERAE—Brassica oleracea* L., cauliflower, kale, Brussels sprouts, cabbage, and broccoli; *B. campestris* L., wild yellow mustard; *Matthiola incana* R. Br., annual stock. Experimentally, also *Brassica adpressa* Boiss; *B. alba* Rabenh., white mustard; *B. arvensis* (L.) Ktze., charlock; *B. juncea* Coss., leaf mustard (one strain not susceptible); *B. napus* L., rape; *B. pe-tsai* Bailey, pe-tsai; *B. nigra* Koch, black mustard; *B. rapa* L., turnip; *Capsella bursa-pastoris* Medic., shepherd's purse; *Iberis amara* L., rocket candytuft; *Lepidium sativum* L., garden cress; *Lunaria annua* L., honesty; *Raphanus raphanistrum* L., white charlock; *R. sativus* L., radish.

Insusceptible species: *CHENOPODIACEAE—Spinacia oleracea* L. *COMPOSITAE—Lactuca sativa* L. *CRUCIFERAE—Alyssum saxatile* L.; *A. maritimum* Lam.; *Arabis albida* Stev.; *Athysanus pusillus* Greene; *Brassica juncea* Coss. (Japanese strain; another strain susceptible); *Cheiranthus cheiri* L.; *Erysimum perofskianum* Fisch. and Mey.; *Hesperis matronalis* L.; *Malcomia maritima* R. Br.; *Roripa nasturtium* Rusby; *Stanleya pinnata* (Pursh.) Britt.; *Thysanocarpus radians* Benth. *LEGUMINOSAE—Vicia faba* L. *SOLANACEAE—Capsicum frutescens* L.; *Lycoper-*

sicon esculentum Mill.; *L. pimpinellifolium* Mill.; *Nicotiana glutinosa* L.; *N. langsdorffii* Weinm.; *N. tabacum* L. vars. Turkish and White Burley. *TROPAEOLACEAE—Tropaeolum majus* L. *UMBELLIFERAE—Apium graveolens* L.

Geographical distribution: United States, England.

Induced disease: In cauliflower, clearing of veins, followed by mild chlorotic mottling, veins usually banded with dark green, necrotic flecks later in chlorotic areas. Midrib curved, leaves distorted. Plant stunted; terminal head or curd dwarfed. Solanaceous plants appear to be immune, a point of distinction between this virus and turnip-mosaic virus, *Marmor brassicae*.

Transmission: By inoculation of expressed juice, using carborundum powder. By many aphid species, *Brevicoryne brassicae* (Linn.), cabbage aphid; *Rhopalosiphum pseudobrassicae* Davis, false cabbage aphid; *Myzus persicae* (Sulz.), peach aphid; *Aphis graveolens* Essig, celery leaf aphid; *A. apigraveolens* Essig, celery aphid; *A. middletonii* Thomas, erigeron root aphid; *A. gossypii* Glov., cotton aphid; *Cavariella capreae* (Fabr.), yellow willow aphid; *Myzus circumflexus* (Buckt.), lily aphid; *Rhopalosiphum melliferum* (Hottes), honeysuckle aphid. (*APHIDIDAE*). No seed transmission.

Thermal inactivation: At 75° C in 10 minutes.

Literature: Caldwell and Prentice, Ann. Appl. Biol., *29*, 1942, 366–373, 374–379; Rawlins and Tompkins, Phytopath., *24*, 1934, 1147 (Abst.); Tompkins, Jour. Agr. Res., *55*, 1937, 33–46.

14. Marmor brassicae H. (H., *loc. cit.*, 70; *Marmor matthiolae* H., *loc. cit.*, 71.) From New Latin, *Brassica*, generic name of turnip.

Common name: Turnip-mosaic virus.

Hosts: *CRUCIFERAE—Brassica rapa* L., turnip; *B. napobrassica* Mill., swede or rutabaga; *B. napus* L., rape; *B. nigra* (L.) Koch, black mustard; *B. oleracea* L., cabbage; *Armoracia rusticana* Gaertn., horse-radish; *Cheiranthus cheiri* L., wallflower; *Matthiola incana* R. Br., stock; *Sinapis alba* L., white mustard. Experimentally, also *CRUCIFERAE—Berteroa incana* (L.) DC.; *Brassica alba* Rabenh., white mustard; *B. arvensis* (L.) Ktze.; *B. chinensis* L., Chinese cabbage; *B. juncea* (L.) Coss.; *Capsella bursa-pastoris* (L.) Medic.; *Cardamine heterophylla* (Forst. f.) O. E. Schultz; *Cheiranthus allionii* Hort.; *Coronopus didymus* Smith; *Hesperis matronalis* L.; *Lepidium ruderale* L.; *L. sativum* L., *L. virginicum* L.; *Nasturtium officinale* R. Br.; *Neslia paniculata* (L.) Desv.; *Radicula palustris* (L.) Moench.; *Raphanus sativus* L.; *Sisymbrium altissimum* L.; *S. officinale* (L.) Scop.; *Thlaspi arvense* L. *CHENOPODIACEAE—Beta vulgaris* L.; *Spinacia oleracea* L., spinach. *COMPOSITAE—Calendula officinalis* L. *Zinnia elegans* Jacq. *RANUNCULACEAE—Delphinium ajacis* L. *SOLANACEAE—Lycopersicon pimpinellifolium* Mill.; *Nicotiana bigelovii* S. Wats.; *N. glutinosa* L.; *N. langsdorffii* Weinm.; *N. repanda* Willd.; *N. rustica* L.; *N. sylvestris* Speg. and Comes; *N. tabacum* L., tobacco; *Petunia hybrida* Vilm.

Geographical distribution: United States, England, New Zealand.

Induced disease: In turnip, systemic chlorotic mottling; plants stunted, leaves distorted. In tobacco, experimentally, characteristic necrotic primary lesions only.

Transmission: By inoculation of expressed juice. By cabbage aphid, *Brevicoryne brassicae* (Linn.), and by the peach aphid, *Myzus persicae* (Sulz.) (*APHIDIDAE*).

Thermal inactivation: At 54° C in 10 minutes.

Strains: A considerable number of strains of this virus appear to occur in nature, but those that have been studied often have been considered as distinct viruses and not compared with each other

under identical circumstances. More work is needed to show existing alliances.

Literature: Chamberlain, New Zealand Jour. Agr., *53*, 1936, 321–330; New Zealand Jour. Science and Technology, *21*, 1939, 212A–223A; Clayton, Jour. Agr. Res., *40*, 1930, 263–270; Gardner and Kendrick, *ibid.*, *22*, 1921, 123–124; Hoggan and Johnson, Phytopath., *25*, 1935, 640–644; Larson and Walker, Jour. Agr. Res., *59*, 1939, 367–392; *62*, 1941, 475–491; Schultz, Jour. Agr. Res., *22*, 1921, 173–178; Smith, Ann. Appl. Biol., *22*, 1935, 239–242; Tompkins, Jour. Agr. 15. **Marmor betae** H. (*loc. cit.*, 72). From Latin *beta*, beet.

Common name: Sugar-beet mosaic virus.

Hosts: *CHENOPODIACEAE—Beta vulgaris* L., beet; *Spinacia oleracea* L., spinach.

Geographical distribution: France, Denmark, Germany, Sweden, United States, England.

Induced disease: In beet, discrete yellowish secondary lesions or clearing of veins on young leaves, followed by chlorotic mottling of newly formed leaves. Darkening of vascular tissue. Leaves bend back near tips, which sometimes die. Intracellular bodies formed. In spinach, 6 to 21 days after infection, chlorotic flecks on young leaves. Plant stunted, outer leaves killed, dying from their tips back. Center of plant survives for a time, but finally dies.

Transmission: By inoculation of expressed juice, in dilutions to 10^{-3}. By aphids, *Myzus persicae* (Sulz.), *Aphis rumicis* Linn., and perhaps *Macrosiphum solanifolii* Ashm. (= *M. gei* Koch) (*APHIDIDAE*). No seed transmission.

Thermal inactivation: At 55 to 60° C in 10 minutes.

Other properties: Inactivated by standing in expressed juice for 24 to 48 hours at about 70° F.

Literature: Böning, Forsch. Geb. Pflanzenkr. u. Immun. Pflanzenreich, *3*, 1927 81–128; Cent. f. Bakt., II Abt., *71*, 1927, 490–497; Gratia and Manil, Compt. rend. Soc. Biol., Paris, *118*, 1935, 379–381; Hoggan, Phytopath., *23*, 1933, 446–474; Jones, Washington Agr. Exp. Sta. Bull. 250, 1931; Lind, Tidsskr. Planteavl, *22*, 1915, 444–457; Robbins, Phytopath., *11*, 1921, 349–365; Schmidt, Ber. Deutsch. Bot. Ges., *45*, 1927, 598–601.

16. **Marmor lactucae** H. (*loc. cit.*, 84). From Latin *lactuca*, lettuce.

Common name: Lettuce-mosaic virus.

Hosts: *COMPOSITAE—Lactuca sativa* L., lettuce; *Senecio vulgaris* L., groundsel. Experimentally, also *COMPOSITAE—Sonchus asper* Hoffm., prickly sow-thistle. *LEGUMINOSAE—Lathyrus odoratus* L., sweet pea; *Pisum sativum* L., pea.

Insusceptible species: *COMPOSITAE—Sonchus oleraceus* L., *S. arvensis* L., *Taraxacum officinale* Web., *Carduus arvensis* Curt. *CRUCIFERAE—Brassica oleracea* L. *CUCURBITACEAE—Cucumis sativus* L. *SOLANACEAE—Lycopersicon esculentum* Mill., *Nicotiana tabacum* L., *N. glutinosa* L., *Datura stramonium* L.

Geographical distribution: United States, England, Germany, Bermuda.

Induced disease: In lettuce varieties, clearing of veins followed by systemic chlorotic mottling, dwarfing and defective hearting; sometimes by scorching of leaf edges, vein necrosis or necrotic flecking between veins.

Transmission: By inoculation of expressed juice, in dilutions to 1:100 if mixed with a little 0.5 per cent sodium sulphite solution and a trace of powdered carborundum. By aphids, *Myzus persicae* (Sulz.) and *Macrosiphum gei* Koch (*APHIDIDAE*). Through seeds from diseased plants. It is believed that seed-borne virus is the most important source of primary inoculum in the spring.

Thermal inactivation: At 55 to 60° C in 10 minutes.

Filterability: Fails to pass L_1 Pasteur-Chamberland filter.

Literature: Ainsworth and Ogilvie, Ann. Appl. Biol., *26*, 1939, 279–297; Jagger, Jour. Agr. Res., *20*, 1921, 737–740; Newhall, Phytopath., *13*, 1923, 104–106.

17. **Marmor dahliae** H. (*loc. cit.*, 85). From New Latin *Dahlia*, generic name of host plant.

Common name: Dahlia-mosaic virus.

Hosts: *COMPOSITAE—Dahlia pinnata* Cav., dahlia. Experimentally, also *D. imperialis* Roezl.; *D. maxonii* Safford.

Geographical distribution: United States, Holland, Germany, England.

Induced disease: In intolerant varieties of dahlia, chlorotic mottling of foliage, leaf distortion, dwarfing of all stems and of roots, occasionally necrotic streaking of midveins. In tolerant varieties, inconspicuous chlorotic mottling or masked symptoms.

Transmission: By aphid, *Myzus persicae* (Sulz.) (*APHIDIDAE*). By grafting. Not by inoculation of expressed juice. Not through soil. Not through seeds from diseased plants.

Literature: Brierley, Am. Dahlia Soc. Bull., Ser. 9, No. 65, 1933; Contrib. Boyce Thompson Inst., *5*, 1933, 235–288; Goldstein, Bull. Torrey Bot. Club, *54*, 1927, 285–293.

18. **Marmor phaseoli** H. (*loc. cit.*, 87). From New Latin *Phaseolus*, generic name of bean.

Common name: Bean-mosaic virus.

Hosts: *LEGUMINOSAE—Phaseolus vulgaris* L., bean. Experimentally, also *Phaseolus acutifolius* Gray var. *latifolius* Freem.; *P. aureus* Roxb.; *P. calcaratus* Roxb.; *P. lunatus* L.; *Lespedeza striata* (Thunb.) Hook. and Arn.; *Vicia faba* L.; *V. sativa* L., spring vetch.

Insusceptible species: *LEGUMINOSAE—Pisum sativum* L., garden pea; *Lathyrus odoratus* L., sweet pea.

Geographical distribution: World-wide, wherever beans are grown.

Induced disease: In bean, first leaves to be affected are crinkled, stiff, chlorotic; later leaves show chlorotic mottling; leaf margins often rolled down. Optimum temperature for expression of disease, 20 to 28° C, partial masking at 28 to 32° C, complete masking at 12 to 18° C.

Transmission: By inoculation of expressed juice in dilutions to 1:1000, using carborundum or other abrasive powder. By aphids, *Aphis rumicis* Linn., *Macrosiphum* (= *Illinoia*) *solanifolii* Ashm., *M. pisi* Kalt., *Aphis gossypii* Glov., *A. medicaginis* Koch, *A. spiraecola*, *Brevicoryne brassicae* (Linn.), *Hyalopterus atriplicis* Linn., *Macrosiphum ambrosiae* Thos., *Rhopalosiphum pseudobrassicae* Davis, and *Myzus persicae* (Sulz.) (*APHIDIDAE*). In beans, there is seed transmission to 30 to 50 per cent of plants grown from infected parents; pollen from infected plants is said to transmit virus.

Thermal inactivation: At 56 to 58° C in 10 minutes.

Literature: Fajardo, Phytopath., *20*, 1930, 469–494, 883–888; Murphy, *ibid.*, *30*, 1940, 779–784; Murphy and Pierce, *ibid.*, *28*, 1938, 270–273; Parker, Jour. Agr. Res., *52*, 1936, 895–915; Pierce, Phytopath., *24*, 1934, 87–115; Jour. Agr. Res., *49*, 1934, 183–188; *51*, 1935, 1017–1039; Reddick, II Congr. Intern. Path. Comp., 1931, 363–366; Reddick and Stewart, Phytopath., *8*, 1918, 530–534; Richards and Burkholder, Phytopath., *33*, 1943, 1215–1216; Wade and Andrus, Jour. Agr. Res., *63*, 1941, 389–393; Wade and Zaumeyer, U. S. Dept. Agr., Circ. 500, 1938; Walker and Jolivette, Phytopath., *33*, 1943, 778–788; Zaumeyer and Kearns, *ibid.*, *26*, 1936, 614–629; Zaumeyer and Wade, Jour. Agr. Res., *51*, 1935, 715–749.

19. **Marmor leguminosarum** H. (*loc. cit.*, 89). From New Latin *Leguminosae*, family name of pea.

Common name: Pea-mosaic virus.

Hosts: *LEGUMINOSAE—Lathyrus odoratus* L., sweet pea; *Pisum sativum* L., pea; *Trifolium pratense* L., red clover; *Vicia faba* L., broad bean. Experiment-

ally, also *Cicer arietinum* L.; *Desmodium canadense* (L.) DC.; *Lathyrus sativus* L., grass pea; *Lupinus albus* L., white lupine; *L. angustifolius*, blue lupine; *L. densiflorus* Benth.; *L. hartwegii* Lindl.; *L. nanus* Dougl.; *Medicago arabica* Huds., spotted bur clover; *M. hispida* Gaertn., oothed bur clover; *Melilotus alba* Desr., white sweet clover; *M. indica* All., annual yellow sweet clover; *M. officinalis* (L.) Lam., yellow sweet clover; *Phaseolus acutifolius* Gray, tepary bean; *P. vulgaris* L., bean; *Trifolium agrarium* L.; *T. carolinianum* Michx.; *T. dubium* Sibth.; *T. glomeratum* L., cluster clover; *T. hybridum* L., alsike clover; *T. incarnatum* L., crimson clover; *T. procumbens* L.; *T. reflexum* L.; *T. suaveolens*, Persian clover; *Vicia sativa* L., common vetch.

Insusceptible species: All tested species in families other than the *Leguminosae*.

Geographical distribution: United States, British Isles, Europe, New Zealand.

Induced disease: In pea, clearing of veins in young leaves, followed by chlorosis of newly formed leaves, stunting of plant, and systemic chlorotic mottling. In sweet pea, systemic chlorosis and chlorotic mottling, flower colors broken. In lupine, necrotic streak on one side of stem, stunting of plant and bending of growing point to injured side. Plant soon wilts and dies. In *Vicia faba*, mottled leaves contain characteristic isometric crystals in host-cell nuclei (especially within nucleoli) as well as in cell cytoplasm.

Transmission: By inoculation of expressed juice, with ease. By aphids, *Macrosiphum pisi* Kalt., *M. solanifolii* Ashm. (= *M. gei* Koch), and *Aphis rumicis* Linn. (*APHIDIDAE*). Not transmitted through seed.

Serological relationships: Specific precipitin reactions differentiate this virus from tobacco-mosaic virus, tobacco-etch virus, potato-mottle virus, potato mild-mosaic virus, potato aucuba-mosaic virus, and tobacco-ringspot virus.

Thermal inactivation: At 60° C in 10 minutes.

Literature: Chester, Phytopath., *25*, 1935, 686–701; Doolittle and Jones, *ibid.*, *15*, 1925, 763–772; Johnson and Jones, Jour. Agr. Res., *54*, 1937, 629–638; McWhorter, Phytopath., *31*, 1941, 760–761; Murphy and Pierce, *ibid.*, *27*, 1937, 710–721; Osborn, *ibid.*, *27*, 1937, 589–603; Pierce, Jour. Agr. Res., *51*, 1935, 1017–1039; Spierenburg, Tijdschr. Plantenz., *42*, 1936, 71–76; Zaumeyer and Wade, Jour. Agr. Res., *53*, 1936, 161–185.

20. **Marmor pisi** H. (*loc. cit.*, 90). From Latin *pisum*, pea.

Common name: Pea enation-mosaic virus.

Hosts: *LEGUMINOSAE—Pisum sativum* L., pea; *Vicia faba* L., broad bean. Experimentally, also *Lathyrus odoratus* L., sweet pea; *Soja max* (L.) Piper, soy bean; *Trifolium incarnatum* L., crimson clover.

Insusceptible species: *LEGUMINOSAE—Arachis hypogaea* L., peanut; *Medicago sativa* L., alfalfa; *Melilotus alba* Desr., white sweet clover; *M. officinalis* (L.) Lam., yellow sweet clover; *Phaseolus aureus* Roxb., mung bean; *P. vulgaris* L., bean; *Trifolium hybridum* L., alsike clover; *T. pratense* L., red clover; *T. repens* L., white Dutch clover. *SOLANACEAE—Lycopersicon esculentum* Mill., tomato; *Solanum tuberosum* L., potato.

Geographical distribution: United States, perhaps Germany.

Induced disease: In peas, systemic chlorotic mottling; in some varieties, as Alderman, occasional necrotic spots and numerous enations on lower surfaces of leaves. Pods distorted. In broad bean, systemic chlorotic spotting and striping of leaves. In sweet pea and soy bean, experimentally, systemic chlorotic mottling.

Transmission: By inoculation of expressed juice, using carborundum; more readily from aphid-inoculated plants than from mechanically-inoculated plants.

Infective in dilutions to 10^{-3}. By aphids, *Macrosiphum pisi* Kalt. and *M. solanifolii* Ashm. (= *M. gei* Koch) (*APHIDIDAE*), with incubation periods of about 12 hours before the insects can infect. Not through seeds from diseased plants.

Thermal inactivation: At 66° C in 10 minutes.

Literature: Böning, Forsch. Geb. Pflanzenkr. u. Immun. Pflanzenreich, *4*, 1927, 43–111; Johnson and Jones, Jour. Agr. Res., *54*, 1937, 629–638; Loring et al., Proc. Soc. Exp. Biol. and Med., *38*, 1938, 239–241; Osborn, Phytopath., *25*, 1935, 160–177; *28*, 1938, 749–754, 923–934; Pierce, Jour. Agr. Res., *51*, 1935, 1017–1039; Snyder, Phytopath., *24*, 1934, 78–80; Stubbs, *ibid.*, *27*, 1937, 242–266.

21. **Marmor medicaginis** H. (*loc. cit.*, 91). From New Latin *Medicago*, generic name of alfalfa (lucerne).

Common name: Alfalfa-mosaic virus.

Hosts: *LEGUMINOSAE—Medicago sativa* L., alfalfa (lucerne). *SOLANACEAE—Solanum tuberosum* L., potato. Experimentally, also transmissible to many species of dicotyledonous plants (summarized by Price, Am. Jour. Bot., *27*, 1940, 530–541) including *CUCURBITACEAE—Cucumis sativus* L., cucumber. *COMPOSITAE—Zinnia elegans* Jacq., zinnia. *LEGUMINOSAE—Phaseolus vulgaris* L., bean; *Trifolium incarnatum* L., crimson clover. *SOLANACEAE—Capsicum frutescens* L., pepper; *Lycopersicon esculentum* Mill., tomato; *Nicotiana tabacum* L., tobacco.

Geographical distribution: United States.

Induced disease: In alfalfa, systemic chlorotic mottling, tending to be masked at times. In bean, (most varieties) small necrotic primary lesions, reddish brown at periphery. No secondary lesions. Some bean varieties show no lesions after inoculation; one of these, Refugee Rogue, possesses two dominant genes either of which will confer this type of resistance. In tobacco, white necrotic flecks, small rings and arcs on inoculated leaves; later, systemic mottling, followed by production of necrotic oak-leaf patterns; virus content may be low in plants long diseased, especially in summer.

Transmission: By inoculation of expressed juice. By aphids, *Macrosiphum pisi* Kalt. (for typical strain) and *M. solanifolii* Ashm. (for potato-calico strain) (*APHIDIDAE*). Not through seeds from diseased plants.

Immunological relationships: Resistance to superinfection with the type of this virus is conferred by earlier infection with potato-calico virus (now considered a related strain but earlier regarded as distinct), but not by earlier infection with potato-mottle virus, cucumber-mosaic virus, or the Canada-streak strain of potato aucuba-mosaic virus.

Thermal inactivation: At 65 to 70° C in 10 minutes.

Other properties: Sedimentation constant, $73.9 \pm 5.2 \times 10^{-13}$ cm. per sec. in a unit centrifugal field. Specific volume 0.673. Particles spherical or nearly so. Diameter 16.5 millimicrons; weight 2.1×10^{6} times hydrogen unit. Isoelectric point about pH 4.6. Inactivated and, more slowly, hydrolyzed by trypsin.

Literature: Black and Price, Phytopath., *30*, 1940, 444–447; Lauffer and Ross, Jour. Am. Chem. Soc., *62*, 1940, 3296–3300, Pierce, Phytopath., *24*, 1934, 87–115; Price, Am. Jour. Bot., *27*, 1940, 530–541; Ross, Phytopath., *31*, 1941, 394–410, 410–420; Wade and Zaumeyer, Jour. Am. Soc. Agron., *32*, 1940, 127–134; Zaumeyer, Jour. Agr. Res., *56*, 1938, 747–772.

Strains: At least one strain of alfalfa-mosaic virus was formerly considered as an independent virus, causing a disease known as calico in potato. It has now been given varietal rank and distinguished from the type, var. *typicum* Black and Price (Phytopath., *30*, 1940, 446) by the following name:

21a. *Marmor medicaginis* var. *solani* Black and Price (Phytopath., *30*, 1940,

446). From New Latin *Solanum*, generic name of potato.

Common name: Potato-calico strain of alfalfa-mosaic virus. Differing from the type by inducing a more severe disease in potato, in which it is commonly found in nature. (Price and Black, Phytopath., *30*, 1940, 444–447; Dykstra, *ibid.*, *29*, 1939, 917–933; Porter, Potato Assoc. Amer. Proc., *18*, 1931, 65–69; Hilgardia, *6*, 1931, 277–294; *9*, 1935, 383–394.)

22. **Marmor tulipae** H. (*loc. cit.*, 52). From New Latin *Tulipa*, generic name of tulip.

Common name: Tulip color-adding virus.

Hosts: *LILIACEAE—Tulipa gesneriana* L., garden tulip; *T. eichleri* Regel; *T. greigi* Regel.

Insusceptible species: *AMARYLLIDACEAE—Narcissus* sp., narcissus. *IRIDACEAE—Iris germanica* L., iris. *LILIACEAE—Allium cepa* L., onion. *SOLANACEAE—Nicotiana tabacum* L., tobacco.

Geographical distribution: Wherever hybrid tulips are grown.

Induced disease: In tulip, no obvious effect on leaves but dark striping of flower by pigment intensification. Little interference with growth of plant. No intracellular bodies.

Transmission: By hypodermic injections of expressed juice in dilutions to 10^{-6}. By aphids, *Myzus persicae* (Sulz.), *Macrosiphum solanifolii* Ashm. (= *M. gei* Koch, *Illinoia solanifolii* Ashm.), *Aphis* (= *Anuraphis*) *tulipae* B. de Fonsc. (on bulbs), and perhaps *Macrosiphum pelargonii* Kalt. (*APHIDIDAE*). Not through seeds from diseased plants.

Thermal inactivation: At 65 to 70° C in 10 minutes.

Literature: Hughes, Ann. Appl. Biol., *18*, 1931, 16–29; *21*, 1934, 112–119; McWhorter, Phytopath., *22*, 1932, 998 (Abst.); *25*, 1935, 898 (Abst.); Ann. Appl. Biol., *25*, 1938, 254–270.

23. **Marmor mite** H. (*loc. cit.*, 53). From Latin *mitis*, mild.

Common name: Lily latent-mosaic virus.

Hosts: *LILIACEAE—Lilium amabile; L. auratum* Lindl.; *L. canadense* L.; *L. candidum* L.; *L. cernuum; L. chalcedonicum* L.; *L. croceum* Chaix.; *L. davmottiae; L. elegans* Thunb.; *L. formosanum* Stapf.; *L. giganteum; L. henryi* Baker; *L. leucanthum; L. longiflorum* Thunb.; *L. myriophyllum; L. pumilum; L. regale* Wils.; *L. sargentiae* Wils.; *L. speciosum* Thunb.; *L. superbum* L.; *L. testaceum* Lindl.; *L. tigrinum* Ker; *L. umbellatum* Hort.; *L. wallacei; Tulipa gesneriana* L., garden tulip; *T. clusiana* Vent.; *T. linifolia* Regel.

Insusceptible species: *LILIACEAE—Allium cepa* L., onion; *Lilium hansoni* Leichtl. *IRIDACEAE—Iris germanica* L., iris. *SOLANACEAE—Nicotiana tabacum* L., tobacco.

Geographical distribution: Wherever lilies and tulips are cultivated.

Induced disease: In Easter lily, masked symptoms or systemic chlorotic mottling, in either case without necrotic flecking. In tulip, systemic chlorotic mottling in foliage and flower "breaking" (color removal, except in a few varieties in which color intensification occurs instead). Intracellular bodies characterize invaded tissues.

Transmission: By inoculation of expressed juice (rubbing surface of leaves), in both lily and tulip. By plugging and grafting of dormant bulbs of tulip. By aphids, *Myzus persicae* (Sulz.), *Macrosiphum solanifolii* Ashm. (= *M. gei* Koch), and *Aphis* (= *Anuraphis*) *tulipae* B. de Fonsc. (*APHIDIDAE*). Not through seeds from mosaic *Lilium longiflorum*.

Thermal inactivation: At 65 to 70° C in 10 minutes.

Literature: Atanasoff, Bull. Soc. Bot. Bulgarie, *2*, 1928, 51–60; Brierley, Phytopath., *29*, 1939, 3 (Abst.); *30*, 1940, 250–

257; *31*, 1941, 838–843; Brierley and Doolittle, *ibid.*, *30*, 1940, 171–174; Cayley, Ann. Appl. Biol., *15*, 1928, 529–539; *19*, 1932, 153–172; Guterman, Hort. Soc. N. Y., Yearbk., *1930*, 51–102; Hall, Gard. Chron., *93*, 1933, 330–331; Hughes, Ann. Appl. Biol,. *21*, 1934, 112–119; McKay and Warner, Nat. Hort. Mag., *12*, 1933, 179–216; McWhorter, Phytopath., *25*, 1935, 898 (Abst.); Science, *86*, 1937, 179; Ann. Appl. Biol., *25*, 1938, 254–270; Science, *88*, 1938, 411; Ogilvie and Guterman, Phytopath., *19*, 1929, 311–315.

24. **Marmor iridis** H. (*loc. cit.*, 55). From New Latin *Iris*, generic name of iris.

Common name: Iris-mosaic virus.

Hosts: *IRIDACEAE—Iris filifolia* Boiss., *I. tingitana* Boiss. and Reut., and *I. xiphium* L., bulbous irises; *Iris ricardi* Hort.; *I. unguicularis* Poir.; bearded iris, variety William Mohr.

Insusceptible species: *SOLANACEAE—Lycopersicon esculentum* Mill., tomato; *Nicotiana tabacum* L., tobacco; *Petunia hybrida* Vilm., petunia. *LILIACEAE—Tulipa gesneriana* L., tulip.

Geographical distribution: United States (Washington, Oregon, California), Holland, Bulgaria, France, England.

Induced disease: In bulbous irises, dwarfing of plant, chlorotic mottling of foliage, breaking of flowers. Rate of increase in planting stock decreased. Flower breaks usually darker than normal color of flower. Vacuolate intracellular bodies in some affected tissues.

Transmission: By injection of freshly extracted juice of diseased plants into internodal tissue. By aphids, *Macrosiphum* (= *Illinoia*) *solanifolii* Ashm. and *Myzus persicae* (Sulz.) (*APHIDIDAE*).

Literature: Brierley and McWhorter, Jour. Agr. Res., *53*, 1936, 621–635.

25. **Marmor sacchari** H. (*loc. cit.*, 60). From New Latin *Saccharum*, generic name of sugar cane, from Latin *saccharum*, sugar.

Common name: Sugar-cane mosaic virus.

Hosts: *GRAMINEAE—Saccharum officinarum* L., sugar cane; *Holcus sorghum* L., sorghum; *H. sudanensis* Bailey, Sudan grass; *Brachiaria platyphylla* Nash; *Chaetochloa magna* Scribn.; *C. verticillata* Scribn.; *Paspalum boscianum* Fluegge; *Syntherisma sanguinale* Dulac. Experimentally, also *Zea mays* L., corn (maize); *Chaetochloa lutescens* Stuntz; *Echinochloa crusgalli* Beauv.; *Miscanthus sinensis* Anderss., eulalia; *Panicum dichotomiflorum* Michx.; *Pennisetum glaucum* R. Br., pearl millet; *Saccharum narenga* Wall.

Insusceptible species: All tested species other than *Gramineae*.

Geographical distribution: Originally in Far East; now in nearly all countries where sugar cane is grown; believed still to be absent from Mauritius.

Induced disease: In sugar cane, systemic mottling chlorosis, light areas of pattern elongated, but crossing veins. Occasionally, stem cankers. Regularly, discoloration and necrosis in mature inner stalk tissues. Vacuolate intracellular bodies occur in diseased tissues. Canes sometimes recover, spontaneously losing the virus and becoming susceptible to reinfection.

Transmission: By inoculation of expressed juice (puncture through inoculum into young leaf). By aphids, *Aphis maidis* Fitch, *Carolinaia cyperi* Ainslie, *Hysteroneura setariae* (Thomas), and *Toxoptera graminum* Rond.; not by *Sipha flava* Forbes (*APHIDIDAE*). Not by *Draeculacephala mollipes* (Say) (*CICADELLIDAE*).

Serological relationships: Specific neutralizing and precipitating antibodies have been demonstrated.

Thermal inactivation: At 53 to 54° C in 10 minutes in leaf tissues.

Other properties: Active after storage 27 days at −6° C.

Literature: Brandes, Jour. Agr. Res., *19*, 1920, 131–138, 517–522; *24*, 1923, 247–262; Desai, Current Science, *3*, 1935, 18; Forbes and Mills, Phytopath., *33*, 1943, 713–718; Ingram and Summers, Jour. Agr. Res., *52*, 1936, 879–888; Kunkel, Bull. Exp. Sta. Hawaiian Sugar Planters' Assoc., Bot. Ser., *3*, 1924, 115–167; Matz, Jour. Agr. Res., *46*, 1933, 821–839; Rafay, Indian Jour. Agr. Science *5*, 1935, 663–670; Scín, Jour. Dept. Agr. Porto Rico, *14*, 1930, 49–68; Stoneberg, U. S. Dept. Agr., Tech. Bull. 10, 1927; Tate and Vandenberg, Jour. Agr. Res., *59*, 1939, 73–79.

26. **Marmor cepae** H. (*loc. cit.*, 66). From Latin *cepa*, onion.

Common name: Onion yellow-dwarf virus.

Host: *LILIACEAE—Allium cepa* L., onion (the variety *viviparum* Metz. is symptomless when infected and may serve as an unrecognized reservoir of virus).

Geographical distribution: United States, Germany, Czecho-Slovakia, Russia, New Zealand.

Induced disease: In onion (most varieties), yellow streaks at base of developing leaf, followed by yellowing, crinkling, and flattening of newly formed leaves; leaves prostrate, flower stalks bent, twisted, stunted; plants reduced in size, bulbs small, yield of seeds reduced. A few varieties of onion are relatively tolerant, and the tree-onion, var. *viviparum* is symptomless after infection.

Transmission: By inoculation of expressed juice. By 48 of 51 tested species of aphid, principally *Aphis rumicis* Linn., *A. maidis* Fitch, and *Rhopalosiphum prunifoliae* Fitch (*APHIDIDAE*). Not through seeds from diseased plants. Not by contaminated soil.

Thermal inactivation: At 75 to 80° C in 10 minutes.

Other properties: Virus withstands dilution to 10^{-4}, storage at 29° C for about 100 hours and storage at −14° C for more than time tested (6 hours), but is inactivated by drying in leaf tissues.

Literature: Andreyeff, Rev. Appl. Mycol., *17*, 1938, 575–576; Blattny, Ochrana Rostlin, *10*, 1930, 130–138; Bremer, Phytopath. Ztschr., *10*, 1937, 79–105; Brierley and Smith, Phytopath., *34*, 1944, 506–507; Chamberlain and Baylis, New Zealand Jour. Science and Technology, *21*, 1939, 229A–236A; Drake et al., Iowa State Coll. Jour. Science, *6*, 1932, 347–355; Jour. Econ. Ent., *26*, 1933, 841–846; Henderson, Phytopath., *20*, 1930, 115 (Abst.); Iowa State Coll., Research Bull. *188*, 1935, 211–255; Melhus et al., Phytopath., *19*, 1929, 73–77; Porter, U. S. Dept. Agr., Plant Dis. Rept., *12*, 1928, 93; Tate, Iowa State Coll. Jour. Science, *14*, 1940, 267–294.

27. **Marmor scillearum** Smith and Brierley (Phytopath., *34*, 1944, 503.) From New Latin *Scilleae*, name of tribe in which hosts are classed.

Common name: Ornithogalum-mosaic virus.

Hosts: *LILIACEAE* (of the tribe Scilleae)—*Ornithogalum thyrsoides* Jacq.; probably also *Galtonia candicans* Decne.; *Hyacinthus orientalis* L., hyacinth; *Lachenalia* sp.

Insusceptible species: *LILIACEAE* (of the tribe Scilleae)—*Muscari botryoides* Mill.; *Scilla peruviana* L.; *Camassia leichtlinii* (Baker) S. Wats.; *Hyacinthus azureus* (Fenzl.) Baker. *AMARYLLIDACEAE—Pancratium maritimum; Zephyranthus* sp. *IRIDACEAE—Tritonia crocata* (L.) Ker. *LILIACEAE—Agapanthus africanus; Allium cepa*, onion; *A. cernuum* Roth.; *A. fistulosum* L.; *A. porrum* L.; *Gloriosa rothschildiana* O'Brien; *Lilium formosanum* Stapf.; and *L. longiflorum*. *SOLANACEAE—Nicotiana tabacum* L.

Geographical distribution: United States (Oregon; probably also Alabama and presumed to be widespread in plants of the squill tribe, *Scilleae*, of the family *LILIACEAE*).

Induced disease: In *Ornithogalum thyrsoides*, young leaves finely mottled with light and dark green, and becoming more conspicuously mottled with gray or yellow as the leaves mature; flower stalks sometimes boldly marked with light and dark green blotches. In perianth segments, thin longitudinal streaks.

Transmission: By inoculation of expressed juice in the presence of fine carborundum powder, with difficulty. By aphids, *Aphis gossypii* Glov., *Macrosiphum lilii* Monell, *M. solanifolii* Ashm., and *Myzus persicae* (Sulz.); less efficiently by *Myzus circumflexus* (Buckt.) (*APHIDIDAE*).

Key to the species of the Miscellaneous Mosaic-Virus Group.

Many of the following viruses, although described in some detail in the literature, stand in need of reinvestigation to determine additional properties and possible relationships to preceding groups.

I. Affecting species of *MALVACEAE*.
- 28. *Marmor abutilon.*

II. Affecting species of *CELASTRACEAE*.
- 29. *Marmor euonymi.*

III. Affecting species of *OLEACEAE*.
- 30. *Marmor ligustri.*

IV. Affecting species of *LEGUMINOSAE* (and no. 39, other families also).
- 31. *Marmor laburni.*
- 32. *Marmor arachidis.*
- 33. *Marmor trifolii.*
- 34. *Marmor pachyrhizi.*
- 35. *Marmor vignae.*
- 36. *Marmor repens.*
- 37. *Marmor fastidiens.*
- 38. *Marmor iners.*
- 39. *Marmor efficiens.*

V. Affecting species of *GRAMINEAE*.
- 40. *Marmor tritici.*
- 41. *Marmor graminis.*

VI. Affecting species of *MUSACEAE*.
- 42. *Marmor abaca.*

VII. Affecting species of *PASSIFLORACEAE*.
- 43. *Marmor passiflorae.*

VIII. Affecting species of *ROSACEAE*.
- 44. *Marmor flaccumfaciens.*
- 45. *Marmor rosae.*
- 46. *Marmor veneniferum.*
- 47. *Marmor mali.*
- 48. *Marmor fragariae.*
- 49. *Marmor marginans.*
- 50. *Marmor rubi.*
- 51. *Marmor persicae.*
- 52. *Marmor astri.*
- 53. *Marmor rubiginosum.*
- 54. *Marmor cerasi.*
- 55. *Marmor lineopictum.*
- 56. *Marmor pallidolimbatus.*
- 57. *Marmor nerviclarens.*

IX. Affecting species of *VITACEAE*.

58. *Marmor viticola.*

X. Affecting species of *SANTALACEAE*.

59. *Marmor santali.*

XI. Affecting species of *CONVOLVULACEAE* and, experimentally, of other families.

60. *Marmor secretum.*

XII. Affecting species of *GERANIACEAE*.

61. *Marmor pelargonii.*

XIII. Affecting species of *SOLANACEAE* and in most cases also of other families.

62. *Marmor angliae.*

63. *Marmor aevi.*

64. *Marmor raphani.*

XIV. Affecting species of *PRIMULACEAE*.

65. *Marmor primulae.*

XV. Affecting species of *MORACEAE*.

66. *Marmor caricae.*

XVI. Affecting species of *RUTACEAE*.

67. *Marmor italicum.*

28. **Marmor abutilon** H. (*loc. cit.*, 50). From New Latin *Abutilon*, generic name of a host.

Common name: Abutilon-mosaic virus.

Hosts: *MALVACEAE—Abutilon striatum* Dicks. var. *thompsonii* Veitch. Experimentally, also *Abutilon arboreum* Sweet; *A. avicennae* Gaertn.; *A. esculentum* St. Hil.; *A. indicum* Sweet; *A. insigne* Planch.; *A. megapotamicum* St. Hil. and Naud.; *A. regnellii* Miq.; *A. sellowianum* Regel; *A. venosum* Lem.; *A. vitifolium* Presl.; *Althaea ficifolia* Cav.; *A. officinalis* L.; *A. rosea* Cav.; *Anoda hastata* Cav.; *Kitaibelia vitifolia* Willd.; *Malva borealis; M. crispa; M. mauritiana* Mill.; *M. sylvestris* L.; *M. verticillata* L.; *Malvastrum capense* Garcke; *Modiola decumbens* G. Don.; *Sida mollis* Herb.; *S. napaea* Cav.; *Sidalcea candida* A. Gray.

Insusceptible species: *MALVACEAE—Althaea taurinensis; Sidalcea purpurea; Sphaeralcea umbellata* G. Don.

Geographical distribution: Germany, France, England, United States; originally obtained from a single variegated seedling found among green plants of *Abutilon striatum* imported from the West Indies in 1868 by Veitch and Sons; subsequently the infected plant [illegible] propagated vegetatively as an ornamental variety.

Induced disease: In *Abutilon*, systemic chlorotic mottling. Recovery occurs if there is persistent removal of affected leaves, suggesting that the virus does not increase in stems. After recovery, plants are susceptible to reinfection.

Transmission: By grafting, except patch-bark-grafting, which is ineffective. Occasionally through seeds from diseased plants. Not by inoculation of expressed juice. No insect vector is known.

Varieties: Distinctive strains have been noted, but not separately named; one isolate originally occurring in *Abutilon darwini* var. *tesselatum*, seems to belong here; it differs from the type principally in severity of induced disease and in ability to infect *Lavatera arborea*.

Literature: Baur, Ber. d. Deutsch. Bot. Gesellsch., *22*, 1904, 453–460; *24*, 1906, 416–428; *25*, 1907, 410–413; K. Preuss. Akad. Wiss., Sitzungsber., 1906, 11–19; Davis, Ann. Missouri Bot. Gard., *16*, 1929, 145–226; Hertzsch, Ztschr. f. Bot., *20*, 1927, 65–85; Keur, Phytopath., *23*, 1933, 20 (Abst.); *24*, 1934, 12–13 (Abst.); Bull. Torrey Bot. Club, *61*, 1934, 53–70; Lindemuth, Gartenflora, *51*, 1902, 323–

29. **Marmor euonymi** H. (*loc. cit.*, 51). From New Latin *Euonymus*, generic name of host.

Common name: Euonymus-mosaic virus.

Hosts: *CELASTRACEAE—Euonymus japonica* L. f. (sometimes written *Evonymus japonicus*). Probably also *E. radicans* Sieb.

Geographical distribution: Germany.

Induced disease: In *Euonymus japonica*, persistent yellowing along veins.

Transmission: By grafting.

Literature: Baur, Ber. d. Deutsch. Bot. Gesellsch., *26a*, 1908, 711-713; Rischkow, Biol. Zentralbl., *47*, 1927, 752-764.

30. **Marmor ligustri** H. (*loc. cit.*, 52). From New Latin *Ligustrum*, generic name of host, from Latin *ligustrum*, ancient name of privet plant.

Common name: Ligustrum-mosaic virus.

Host: *OLEACEAE—Ligustrum vulgare* L., common privet.

Geographical distribution: Germany.

Induced disease: Systemic chlorotic spotting.

Transmission: By grafting. Not through seeds from diseased plants.

Literature: Baur, Ber. d. Deutsch. Bot. Gesellsch., *25*, 1907, 410-413.

31. **Marmor laburni** H. (*loc. cit.*, 51). From generic name of a host plant, *Laburnum vulgare*.

Common name: Laburnum-mosaic virus.

Hosts: *LEGUMINOSAE—Laburnum vulgare Griseb.* (= *L. anagyroides* Medic.), bean tree. Experimentally, also *Cytisus hirsutus* L.

Insusceptible species: *LEGUMINOSAE—Laburnum alpinum* Griseb.; *Cytisus purpureus*.

Geographical distribution: Germany.

Induced disease: Systemic chlorotic variegation.

Transmission: By bark grafts or by budding. Not through seeds from diseased plants of *Laburnum vulgare*.

Literature: Baur, Ber. d. Deutsch. Bot. Gesellsch., *25*, 1907, 410-413.

32. **Marmor arachidis** H. (*loc. cit.*, 67). From New Latin *Arachis*, generic name of peanut.

Common name: Peanut-rosette virus.

Host: *LEGUMINOSAE—Arachis hypogaea* L., peanut.

Geographical distribution: Union of South Africa, Madagascar, Tanganyika Territory, Uganda, Senegal, Gambia, Sierra Leone, Java.

Induced disease: In peanut, yellowing of young leaves, at first with green veins; reduction in leaf size, petiole length, and internode length, producing rosette; curling and distortion of later-formed, wholly chlorotic or chlorotically mottled leaflets. Seed formation inhibited. No abnormal proliferation of tissues.

Transmission: By grafting. By both winged and wingless individuals of the aphid, *Aphis laburni* Kalt. (= *A. leguminosae* Theob.) (*APHIDIDAE*). Not by 13 tested species of leafhoppers. Not by inoculation of expressed juice. Not through seed from diseased plants. Not through soil.

Literature: Hayes, Trop. Agr., *9*, 1932, 211-217; McClintock, Science, *45*, 1917, 47-48; Soyer, Publ. Inst. Nat. Étud. Agron. Congo Belge, Sér. Sci., *21*, 1939, 23 pages (Rev. Appl. Mycol., *19*, 1940, 386, Abst.); Storey and Bottomley, Ann. Appl. Biol., *15*, 1928, 26-45; Zimmerman, Der Pflanzer, *3*, 1907, 129-133; *9*, 1913, 59-63.

33. **Marmor trifolii** H. (*loc. cit.*, 93). From New Latin *Trifolium*, generic name of red clover, from Latin *trifolium*, clover.

Common name: Red-clover vein-mosaic virus.

Hosts: *LEGUMINOSAE—Trifolium pratense* L., red clover; *Lathyrus odoratus* L., sweet pea; *Vicia faba* L., broad bean. Experimentally, also *Trifolium hybridum* L., alsike clover; *T. incarnatum* L., crim-

son clover; *T. repens* L., white clover; *Melilotus alba* Desr., white sweet clover; *Pisum sativum* L., pea.

Insusceptible species: *LEGUMINOSAE—Phaseolus vulgaris* L., bean; *P. aureus* Roxb., mung bean; *Medicago sativa* L., alfalfa. *SOLANACEAE—Lycopersicon esculentum* Mill., tomato; *Nicotiana tabacum* L., tobacco; *N. glutinosa* L.; *N. langsdorffii* Weinm.; *N. rustica* L.; *N. sylvestris* Spegaz. and Comes; *Solanum tuberosum* L., potato.

Geographical distribution: United States.

Induced disease: In red clover, yellow color along veins, but no mottling. Sometimes small yellow spots in interveinal areas. Little or no stunting. In *Vicia faba*, experimentally, necrotic splotches or rings sometimes at site of inoculation. Clearing of veins followed by appearance of whitish bands along the veins. Stalks discolored, purplish. Diseased plants are stunted and often die back to a point near the base of the stalk, inducing new growth from buds on the stem.

Transmission: By inoculation of expressed juice, using carborundum. By aphid, *Macrosiphum pisi* Kalt. (*APHIDIDAE*), without incubation period and without long retention. Not by aphids, *Macrosiphum solanifolii* Ashm. (= *M. gei* Koch) or *Aphis rumicis* Linn. (*APHIDIDAE*).

Thermal inactivation: At 60° C in 10 minutes.

Literature: Osborn, Phytopath., *27*, 1937, 1051–1058; Zaumeyer, Jour. Agr. Res., *56*, 1938; 747–772; Zaumeyer and Wade, Phytopath., *27*, 1937, 1009–1013.

34. **Marmor pachyrhizi** *spec. nov.* From New Latin *Pachyrhizus*, generic name of sincamas.

Common name: Sincamas-mosaic virus.

Host: *LEGUMINOSAE—Pachyrhizus erosus* (L.) Urb., sincamas (yam bean).

Insusceptible species: *LEGUMINOSAE—Phaseolus vulgaris* L., bean.

Geographical distribution: Philippine Islands.

Induced disease: In sincamas, chlorotic mottling of foliage; in plants infected when young, dwarfing.

Transmission: By inoculation of expressed juice, in the presence of sand as abrasive. Through about 25 percent of the seeds from infected plants. Not through soil, interlacing of roots, or casual contacts of leaves and stems. No insect vector is known.

Literature: Fajardo and Marañon, Philippine Jour. Science, *48*, 1932, 129–142.

35. **Marmor vignae** *spec. nov.* From New Latin *Vigna*, generic name of cowpea, from family name of an Italian botanist, Domenico Vigna.

Common name: Cowpea-mosaic virus.

Hosts: *LEGUMINOSAE—Vigna sinensis* (L.) Endl., cowpea. Experimentally, also *Phaseolus lunatus* L., lima bean.

Geographical distribution: United States (Arkansas, Oklahoma, Louisiana, Indiana, Georgia, Iowa, Mississippi, Kansas, New Jersey).

Induced disease: In cowpea, clearing of veins followed by chlorotic mottling, slight convex cupping of leaflets, shortened internodes, abortion of flowers, twisting of petioles, delayed maturity. Malformation of leaves, stunting of plants, and reduction of yield more pronounced in some varieties of cowpea than in others.

Transmission: By inoculation of expressed juice, especially in the presence of fine carborundum powder. By aphids, *Macrosiphum solanifolii* Ashm., *M. pisi* Kalt., *Aphis gossypii* Glov. (*APHIDIDAE*); not by various beetles nor by the bean leafhopper, *Empoasca fabae* LeB. (*CICADELLIDAE*). Through 5 per cent of seeds from infected cowpea plants.

Thermal inactivation: At 72 to 75° C in 10 minutes.

Other properties: Infectious in dilutions as high as 1:1000 and after 2 days

storage in expressed juice at room temperature, 20 to 25° C.

Literature: Elliott, Phytopath., *11*, 1921, 146–148; Gardner, Indiana Acad. Science Proc., *36*, 1927, 231–247; *37*, 1928, 417; McLean, Phytopath., *31*, 1941, 420–430; Smith, Science, *60*, 1924, 268.

36. **Marmor repens** Johnson. (Phytopath., *32*, 1942, 114.) From Latin *repens*, unlooked for, in reference to unexpected discovery of this virus as a constituent of a complex formerly regarded as a single virus, so-called "white-clover mosaic virus".

Common name: Pea-wilt virus.

Hosts: *LEGUMINOSAE—Trifolium repens* L., white clover. Experimentally, also *Lathyrus odoratus* L., *Lens esculenta* Moench.; *Lupinus albus* L.; *Medicago lupulina* L.; *Melilotus alba* Desr.; *Phaseolus aureus* Roxb., mung bean; *P. vulgaris* L., bean; *Pisum sativum* L., pea; *Trifolium hybridum* L.; *T. incarnatum* L.; *T. pratense* L.; *Vicia faba* L.; *V. sativa* L.; *Vigna sinensis* (L.) Endl., cowpea.

Insusceptible species: *CARYOPHYLLACEAE—Stellaria media* (L.) Cyrill. *CHENOPODIACEAE—Beta vulgaris* L.; *Spinacia oleracea* L. *COMPOSITAE—Callistephus chinensis* Nees; *Lactuca sativa* L.; *Taraxacum officinale* Weber; *Zinnia elegans* Jacq. *CRUCIFERAE—Barbarea vulgaris* R. Br.; *Brassica oleracea* L.; *Raphanus sativus* L. *CUCURBITACEAE—Cucumis sativus* L. *GRAMINEAE—Zea mays* L. *LEGUMINOSAE—Glycine max* Merr.; *Lupinus hirsutus* L.; *Medicago sativa* L. *LILIACEAE—Lilium formosanum* Stapf. *PLANTAGINACEAE—Plantago lanceolata* L.; *P. major* L. *POLYGONACEAE—Rumex acetosella* L. *SCROPHULARIACEAE — Antirrhinum majus* L. *SOLANACEAE—Datura stramonium* L.; *Lycopersicon esculentum* Mill.; *Nicotiana glutinosa* L.; *N. rustica* L.; *N. sylvestris* Spegaz. and Comes; *N. tabacum* L.; *Solanum nigrum* L.

Geographical distribution: United States (Washington).

Induced disease: In white clover, systemic chlorotic mottling. In pea, experimentally, originally infected leaves wilt and die, remaining attached to the stem by their shriveled petioles; a few adjacent lower leaves may also wilt and die; in most varieties the top foliage remains green, but in two varieties, Alaska and Canada White, it mottles faintly; stems show faint grayish discoloration; plants are retarded in growth and dwarfed. If pea-mottle virus, *Marmor efficiens* Johnson, is also present, a severe streak disease occurs. Intracellular inclusions absent. In mung bean, experimentally, necrotic zonate local lesions. In cowpea, experimentally, brown necrotic local lesions in inoculated primary leaves, diffuse areas of bleaching in uninoculated trifoliate leaves. In bean, experimentally, mild chlorotic mottling except in three varieties that appear insusceptible (varieties Ideal Market, Kentucky Wonder, and Navy Robust).

Transmission: By inoculation of expressed juice. Not by dodder, *Cuscuta campestris* Yunck. (*CONVOLVULACEAE*). Not by pea aphid, *Macrosiphum pisi* Kalt. (*APHIDIDAE*). No insect vector is known.

Thermal inactivation: At 58 to 60° C in 10 minutes.

Filterability: Passes Berkefeld W filter candle.

Other properties: Infectious in dilution of 1:100,000. Not inactivated by storage in juice of infected plants at about 25° C for one month or by similar storage in dried tissues of infected pea plants.

Literature: Johnson, Phytopath., *32*, 1942, 103–116; Pierce, Jour. Agr. Res., *51*, 1935, 1017–1039.

37. **Marmor fastidiens** *spec. nov.* From Latin *fastidiens*, disdaining, in reference to slight irregularities in the reported host ranges of constituent strains and failure of this virus to infect certain varieties of the pea although it

may utilize many other varieties of this species as host.

Common name: Alsike-clover mosaic virus.

Hosts: *LEGUMINOSAE—Trifolium hybridum* L., alsike clover; *Pisum sativum* L., pea (except the varieties Horal, Perfection, and Surprise). Experimentally, also *Crotalaria striata* DC.; *C. retusa* L.; and *C. spectabilis* Roth (the two last-named species are reported to be insusceptible to the type strain of the virus, but susceptible to one or more of the other tested strains); *Lupinus albus* L.; *L. angustifolius* L.; *Medicago sativa* L.; *Melilotus alba* Desr.; *Phaseolus vulgaris* L., bean; *Trifolium incarnatum* L.; *T. pratense* L.; *Vicia faba* L.

Insusceptible species: *SOLANACEAE—Datura stramonium* L.; *Nicotiana glauca* Graham; *N. glutinosa* L.; *N. tabacum* L.; *Petunia hybrida* Vilm. *LEGUMINOSAE—Phaseolus aureus* Roxb., mung bean; *P. lunatus* L., sieva bean; *Soja max* (L.) Piper, soybean; *Trifolium repens* L., white clover; *Vicia sativa* L., spring vetch.

Induced disease: In pea and bean, experimentally, systemic chlorotic mottling; some isolates kill inoculated leaves and even cause death of infected plants.

Transmission: By inoculation with expressed juice, at dilutions to 1:6000 or 1:8000. No insect vector is known.

Thermal inactivation: At 60 to 65° C in 10 minutes; one strain at lower temperature, 54 to 58° C.

Strains: Several strains have been distinguished by the severity of their effects on host plants. These may be characterized as follows: var. *fastidiens, var. nov.*, type variety, the first of the strains to be described (originally known as alsike clover mosaic virus 1), induces mild disease in pea, does not infect red clover; var. *mite, var. nov.*, described as pea mosaic virus 4, induces mild symptoms on pea, infects red clover; var. *reprimens, var. nov.*, described as pea mosaic virus 5, stunts peas severely; var. *denudans, var. nov.*, described as alsike clover mosaic virus 2, defoliates pea plants. Varietal names from New Latin *fastidiens*, epithet of the species, and from Latin *mitis*, mild; *reprimere*, to restrain; and *denudare*, to denude; all three in reference to induced symptoms.

Literature: Wade and Zaumeyer, Phytopath., *28*, 1938, 505–511; Zaumeyer, Jour. Agr. Res., *60*, 1940, 433–452.

38. **Marmor iners** *spec. nov.* From Latin *iners*, sluggish or inert, in reference to failure of the virus to spread systemically in certain of its hosts.

Common name: Pea-streak virus.

Hosts: *LEGUMINOSAE—Pisum sativum* L., pea. Experimentally, also *Galega officinalis* L., goat's rue; *Glycine soja* Sieb. and Zucc., soya bean; *Lathyrus odoratus* L., sweet pea; *Lotus hispidus* Desf.; *Lupinus angustifolius* L., blue lupin; *L. luteus* L., yellow lupin; *L. mutabilis* Sweet; *Phaseolus vulgaris* L., bean; *Trifolium arvense* L., haresfoot trefoil; *T. cernuum* Brot., nodding clover; *T. fragiferum* L., strawberry clover; *T. glomeratum* L., cluster clover; *T. hybridum* L., alsike clover; *T. pratense* L., red clover; *T. repens* L., white clover; *Vicia villosa* Roth., hairy vetch. *CUCURBITACEAE—Cucumis melo* L., rock melon; *C. sativus* L., cucumber; *Cucurbita pepo* L., marrow.

Insusceptible species: *CHENOPODIACEAE—Spinacia oleracea* L., spinach; *Beta vulgaris* L., beet. *COMPOSITAE—Calendula officinalis* L., calendula; *Lactuca sativa* L., lettuce; *Zinnia elegans* Jacq., zinnia. *CRUCIFERAE—Brassica napus* L., swede; *B. oleracea* L., cabbage; *B. rapa* L., turnip; *Matthiola incana* R. Br., stock; *Raphanus sativus* L., radish; *Sisymbrium officinale* (L.) Scop., hedge mustard. *LEGUMINOSAE—Arachis hypogaea* L., peanut; *Lathyrus latifolius* L., perennial sweet pea; *L. pubescens* Hook. and Arn., Argentine sweet pea; *Lotus corniculatus* L.; *Lupinus arboreus* Sims, tree lupin; *Medicago arabica* Huds.; *M. sativa* L., lucerne (alfalfa); *Phaseolus multiflorus* Willd., run-

ner bean; *Trifolium striatum* L., striated clover; *T. subterraneum* L., subterranean clover; *Vicia faba* L., broad bean. *PLANTAGINACEAE* — *Plantago lanceolata* L., plantain. *SCROPHULARIACEAE*—*Antirrhinum majus* L. *SOLANACEAE*—*Cyphomandra betacea* Sendt., tree tomato; *Datura stramonium* L., Jimson weed; *Nicotiana glauca* R. Grah.; *N. rustica* L., Turkestan tobacco; *N. tabacum* L., tobacco; *Physalis peruviana* L., Cape gooseberry; *Solanum nigrum* L., black nightshade. *TROPAEOLACEAE*—*Tropaeolum majus* L., nasturtium. *UMBELLIFERAE*—*Apium graveolens* L., celery.

Geographical distribution: New Zealand.

Induced disease: In the pea, stunting, wilting of young leaves, purple or purple-brown spotting on young leaves, dark streak on stem. Near tip, stem may die. Stem becomes brittle, tip bent to one side. Pods may remain flat and turn dark purple or purple-brown, or if already formed may show purple or purple-brown markings. Older leaves turn yellow, then brown and shrivelled. Infected plants usually die within two or three weeks. In inoculated plants small brown primary lesions, rapidly increasing in size especially along veins, eventually involve the whole leaf; petiole and stem streak follows. Among garden peas, the varieties Pride of the Market, Little Marvel, Wm. Massey and Autocrat are little affected; among field peas, the varieties Unica and White Ivory are equally resistant. In cucumber, experimentally, numerous brown, necrotic local lesions, each with light colored center and surrounding light-yellow halo. In bean, experimentally, local and systemic necrosis, stem streak, death of plant.

Transmission: By inoculation of expressed juice, best with an abrasive powder such as fine sand. Not by *Myzus persicae* (Sulz.), *Macrosiphum solani* (*APHIDIDAE*), nor *Thrips tabaci* Lind. (*THRIPIDAE*). No insect vector is known.

Thermal inactivation: At 78 to 80° C in 10 minutes.

Filterability: Passes Mandler filters of preliminary, regular, and fine grades.

Other properties: Dilution end point $1:10^6$. Not inactivated at room temperature in 41 days.

Literature: Chamberlain, New Zealand Jour. Science and Technology, *20*, 1939, 365A–381A.

39. **Marmor efficiens** Johnson. (Phytopath., *32*, 1942, 114.) From Latin *efficiens*, effective, in reference to ability of this virus to cause mottling in all tested varieties of pea in contrast with inability of pea-wilt virus, a second constituent of the complex earlier known as "white-clover mosaic virus," to produce such chlorotic symptoms in tested varieties other than Alaska and Canada White.

Common name: Pea-mottle virus.

Hosts: *LEGUMINOSAE*—*Trifolium repens* L., white clover; *Pisum sativum* L., pea. Experimentally, also *CARYOPHYLLACEAE*—*Stellaria media* (L.) Cyrill. *CHENOPODIACEAE*—*Spinacia oleracea* L., spinach. *CUCURBITACEAE*—*Cucumis sativus* L. *LEGUMINOSAE*—*Lathyrus odoratus* L.; *Lens esculenta* Moench.; *Lupinus albus* L.; *L. hirsutus* L.; *Medicago lupulina* L.; *M. sativa* L., alfalfa (lucerne); *Melilotus alba* Desr.; *Phaseolus aureus* Roxb.; *P. vulgaris* L., bean; *Trifolium hybridum* L.; *T. incarnatum* L.; *T. pratense* L.; *Vicia faba* L.; *V. sativa* L. *SCROPHULARIACEAE*—*Antirrhinum majus* L.

Insusceptible species: *CHENOPODIACEAE*—*Beta vulgaris* L., sugar beet. *COMPOSITAE*—*Callistephus chinensis* Nees; *Lactuca sativa* L.; *Taraxacum officinale* Weber; *Zinnia elegans* Jacq. *CRUCIFERAE*—*Barbarea vulgaris* R. Br.; *Brassica oleracea* L.; *Raphanus sativus* L. *GRAMINEAE*—*Zea mays* L. *LEGUMINOSAE*—*Glycine max* Merr.; *Vigna sinensis* (L.) Endl. *LILIACEAE*—*Lilium formosanum* Stapf. *PLANTAGINACEAE* — *Plantago*

lanceolata L.; *P. major* L. *POLYGONACEAE*—*Rumex acetosella* L. *SOLANACEAE*—*Datura stramonium* L.; *Lycopersicon esculentum* Mill.; *Nicotiana glutinosa* L.; *N. rustica* L.; *N. sylvestris* Spegaz. and Comes; *N. tabacum* L.; *Solanum nigrum* L.

Geographical distribution: United States (Washington).

Induced disease: Experimentally, in pea, developing leaves late in opening; clearing of veins, chlorotic spotting, stunting, chlorotic mottling; stipules mottled; stems, pods, and seeds appear normal. If pea-wilt virus (*Marmor repens* Johnson) is also present, a severe streak disease occurs. Intracellular inclusions absent. In bean, light yellow spots and clearing of veins. In spinach, severe chlorotic mottling, dwarfing. In alfalfa, streaks of yellowing along veins, chlorotic mottling.

Transmission: By inoculation of expressed juice. By dodder, *Cuscuta campestris* Yunck. (*CONVOLVULACEAE*). Not by pea aphid, *Macrosiphum pisi* Kalt. (*APHIDIDAE*). No insect vector is known.

Thermal inactivation: At 60 to 62° C in 10 minutes.

Filterability: Passes Berkefeld W filter candle.

Other properties: Infectious in dilution of 1:10,000 and after storage in expressed juice or dried tissues for one month at about 25° C.

Literature: Johnson, Phytopath., *32*, 1942, 103–116; Johnson and Jones, Jour. Agr. Res., *54*, 1937, 629–638; Pierce, *ibid.*, *51*, 1935, 1017–1039; Zaumeyer and Wade, *ibid.*, *51*, 1935, 715–749.

40. **Marmor tritici** H. (*loc. cit.*, 61). From Latin *triticum*, wheat.

Common names: Wheat-mosaic virus, wheat-rosette virus.

Hosts: *GRAMINEAE*—*Triticum aestivum* L., wheat; *Secale cereale* L., rye. Experimentally, also all tested species of the tribe Hordeae; *Triticum compactum* Host; *T. turgidum* L.; *T. durum* Desf.; *T. dicoccum* Schrank; *T. spelta* L.; *T. polonicum* L.; *T. monococcum* L., *Hordeum vulgare* L., barley.

Insusceptible species: *GRAMINEAE*—*Bromus inermis* Leyss., awnless brome-grass (of the tribe *Festuceae*).

Geographical distribution: United States, Japan.

Induced disease: In wheat, systemic chlorotic mottling, with dwarfing in some varieties; vacuolate, rounded intracellular bodies in diseased cells, usually close to nucleus. Some selections of Harvest Queen wheat are resistant.

Transmission: Through soil; remains infectious in soil 6 or more years. By inoculation of expressed juice (needle punctures in stem). Not through seeds or stubble of diseased plants. No insect vector is known.

Thermal inactivation: Contaminated soil becomes incapable of infecting wheat plants if heated for 10 minutes at 60° C though not if heated for the same length of time at 50° C.

Literature: Johnson, Science, *95*, 1942, 610; McKinney, Jour. Agr. Res., *23*, 1923, 771–800; U. S. Dept. Agr., Bull. 1361, 1925; U. S. Dept. Agr., Circ. 442, 1937; Jour. Agr. Res., *40*, 1930, 547–556; McKinney et al., *ibid.*, *26*, 1923, 605–608; Wada and Hukano, Agr. and Hort., *9*, 1934, 1778–1790 (Rev. Appl. Mycol., *14*, 1935, 618, Abst.); Jour. Imp. Agr. Exp. Sta., *3*, 1937, 93–128 (Rev. Appl. Mycol., *16*, 1937, 665, Abst.); Webb, Jour. Agr. Res., *35*, 1927, 587–614; *36*, 1928, 53–75.

41. **Marmor graminis** McKinney. (Jour. Washington Acad. Sci., *34*, 1944, 325.) From Latin *gramen*, grass.

Common name: Brome-grass mosaic virus.

Hosts: *GRAMINEAE*—*Bromus inermis* Leyss., awnless brome-grass. Experimentally, also *Triticum aestivum* L., wheat; *Avena sativa* L., oat.

Geographical distribution: United States (Kansas).

Induced disease: In awnless brome-grass, systemic chlorotic mottling of the

type commonly called yellow mosaic because of the distinctly yellow color of the chlorotic areas in affected leaves.

Transmission: By inoculation of expressed juice or of aqueous suspensions of dried diseased tissues; not inactivated by drying in diseased tissues for at least 51 days. No insect vector is known.

Literature: McKinney et al., Phytopath., *32*, 1942, 331.

42. **Marmor abaca** H. (*loc. cit.*, 63). From common name of host plant.

Common name: Abacá bunchy-top virus.

Host: *MUSACEAE—Musa textilis* Née, abacá (Manila hemp plant).

Insusceptible species: *MUSACEAE—Musa sapientum* L. vars. *cinerea* (Blanco) Teodoro, *compressa* (Blanco) Teodoro, *lacatan* (Blanco) Teodoro, and *suaveolens* (Blanco) Teodoro; *M. cavendishii* Lamb.

Geographical distribution: Philippine Islands.

Induced disease: In abacá (Manila hemp plant), chlorotic lines and spots along veins of young leaves, followed by growth of distorted leaves, successively shorter, narrower, stiffer, and more curled along their margins. The green areas of mottled leaves, petioles, and leaf sheaths are darker than normal. Newly formed diseased leaves unfurl early, but are short, producing the bunchy top that is referred to in the common name of the disease.

Transmission: By the aphid, *Pentalonia nigronervosa* Coq. (*APHIDIDAE*), vector also of the apparently distinct banana bunchy-top virus of Australia. The incubation period of abacá bunchy-top virus in this aphid is between 24 and 48 hours in length. The progeny of viruliferous aphids do not receive the virus directly, but must feed on diseased plants before they can infect healthy abacá. Transmission by inoculation of expressed juice has not been demonstrated. No soil transmission.

Literature: Ocfemia, Am. Jour. Bot., *17*, 1930, 1–18; Philippine Agriculturist, *22*, 1934, 567–581.

43. **Marmor passiflorae** H. (*loc. cit.*, 77). From New Latin *Passiflora*, generic name of passion fruit.

Common name: Passion-fruit woodiness virus.

Hosts: *PASSIFLORACEAE—Passiflora edulis* Sims, passion fruit; *P. coerulea* L. Experimentally, also *P. alba* Link and Otto.

Insusceptible species: *SOLANACEAE—Datura stramonium* L.; *Lycopersicon esculentum* Mill., tomato; *Nicotiana glutinosa* L.; *N. tabacum* L., tobacco.

Geographical distribution: Australia (New South Wales, Queensland, Victoria), Kenya.

Induced disease: In passion fruit, growth checked; leaves puckered, slightly chlorotic or obscurely mottled, curled, twisted, deformed. Clearing of veins has been observed. Color of stems darker green than normal in some places. Fruits short or deformed, discolored, surface sometimes roughened by cracks; so hard as not to be cut through readily. Pericarp or rind of fruit abnormally thick. Pulp deficient, color deepened. At temperatures below 80° F, some abscission of young chlorotic leaves; above 85° F, masking of the disease in most plants.

Transmission: By inserting cotton in stem wound after soaking it in expressed juice of diseased plant. By aphids, *Myzus persicae* (Sulz.), *Macrosiphum solanifolii* Ashm., and two dark-colored species of the genus *Aphis* (*APHIDIDAE*).

Literature: Cobb, Agr. Gaz. New South Wales, *12*, 1901, 407–418; Noble, Jour. and Proc. Roy. Soc. New South Wales, *62*, 1928, 79–98; Noble and Noble, *ibid.*, *72*, 1939, 293–317; Simmonds, Queensland Agr. Jour., *45*, 1936, 322–330.

44. **Marmor flaccumfaciens** H. (*loc. cit.*, 73). From Latin *flaccus*, flabby, and *facere*, to make.

Common names: Rose-wilt virus, rose dieback virus.

Hosts: *ROSACEAE—Rosa* hybrids, roses.

Geographical distribution: Australia, especially Victoria; New Zealand; possibly Italy.

Induced disease: In rose, leaflets crowded, brittle, recurved. Defoliation progresses from tip to base of plant. Tips of branches discolor and die back an inch or two. Stem darkens at base. Buds remain green and begin development, but growth is soon checked by necrosis at tips. Plant may recover temporarily, but not permanently.

Transmission: By inoculation of expressed juice (needle-puncture and scratch methods). No insect vector is known.

Filterability: Passes Seitz filter (Seitz EK Schichten type, size 6).

Literature: Gigante, Boll. Staz. Pat. Veg. Roma, n. s. *16*, 1936, 76–94; Grieve, Austral. Jour. Exp. Biol. and Med. Science, *8*, 1931, 107–121; Jour. Dept. Agr. Victoria, 1932 and 1933, pages 30–32.

45. **Marmor rosae** H. (*loc. cit.*, 74). From Latin *rosa*, rose.

Common name: Rose-mosaic virus.

Hosts: *ROSACEAE—Rosa rugosa* Thunb.; *R. chinensis* Jacq. var. *manetti* Dipp.; *R. multiflora* Thunb.; *R. odorata* Sweet, tea rose; *R. gymnocarpa*; *Rubus parviflorus* Nutt.

Geographical distribution: United States, England, Bulgaria, Brazil.

Induced disease: In *Rosa rugosa* and *R. chinensis* var. *manetti*, systemic chlorotic mottling.

Transmission: By budding and other forms of graftage. Not by inoculation of expressed juice. No insect vector is known.

Literature: Baker and Thomas, Phytopath., *32*, 1942, 321–326; Brierley, Phytopath., *25*, 1935, 8 (Abst.); Brierley and Smith, Am. Nurseryman, *72*, 1940, 5–8; Jour. Agr. Res., *61*, 1940, 625–660; Kramer, Revista de Agricultura, *15*, 1940, 301–311; O Biologico, *6*, 1940, 365–368; McWhorter, U. S. Dept. Agr., Plant Dis. Rep., *15*, 1931, 1–3; Milbrath, West. Florist, *13*, 1930, 29–30; Nelson, Phytopath., *20*, 1930, 130 (Abst.); Newton, Rep. Domin. Bot., 1930, Div. Bot., Canad. Dept. Agr., 1931, 23; Thomas and Massey, Hilgardia, *12*, 1939, 645–663; Vibert, Jour. Soc. Imp. et Cent. Hort., *9*, 1863, 144–145; White, Phytopath., *22*, 1932, 53–69; *24*, 1934, 1124–1125.

46. **Marmor veneniferum** H. (*loc. cit.*, 75). From Latin *venenifer*, poisonous, in reference to occasional killing of tissues near inserted bud in graft transmission.

Common name: Rose-streak virus.

Hosts: *ROSACEAE—Rosa multiflora* Thunb.; *R. odorata* Sweet; *Rosa* hybrids.

Geographical distribution: Eastern United States.

Induced disease: In various rose species and hybrids, brownish or reddish ring and veinbanding patterns on leaves, and ring patterns on stems. Sometimes necrotic areas near inserted bud, causing girdling of stem and wilting of foliage.

Transmission: By grafting. Not by inoculation of expressed juice. No insect vector is known.

Literature: Brierley, Phytopath., *25*, 1935, 7–8 (Abst.); Brierley and Smith, Jour. Agr. Res., *61*, 1940, 625–660.

47. **Marmor mali** H. (*loc. cit.*, 75). From Latin *malus*, apple tree.

Common name: Apple-mosaic virus.

Hosts: *ROSACEAE—Pyrus malus* L., apple. Experimentally, also *Cotoneaster harroviana*; *Eriobotrya japonica* Lindl., loquat; *Photinia arbutifolia* Lindl., toyon; *Rosa* sp., rose; *Sorbus pallescens*.

Insusceptible species: *ROSACEAE—Amelanchier alnifolia* Nutt.; *Crataegus douglasii* Lindl.; *Pyrus communis* L., pear.

Geographical distribution: United States, Australia, Bulgaria, British Isles.

Induced disease: In apple, clearing of veins and systemic chlorotic spotting. The chlorotic areas sometimes become necrotic during months of intense sunlight.

Transmission: By grafting. No insect

vector is known. Transmission by inoculation of expressed juice has not been demonstrated.

Thermal inactivation: Not demonstrated. Virus in stem tissues withstands at least 50° C for as much as 60 minutes without being inactivated.

Literature: Blodgett, Phytopath., *28*, 1938, 937-938; Bradford and Joley, Jour., Agr. Res., *46*, 1933, 901-908; Christoff, Phytopath. Zeitschr., *7*, 1934, 521-536; *8*, 1935, 285-296; Thomas, Hilgardia, *10*, 1937, 581-588.

48. **Marmor fragariae** H. (*loc. cit.*, 78). From New Latin *Fragaria*, generic name of strawberry, from Latin *fraga*, strawberries.

Common name: Strawberry-crinkle virus.

Hosts: *ROSACEAE—Fragaria* hybrids, cultivated strawberries. Experimentally, also *Fragaria vesca* L., woodland strawberry.

Geographical distribution: United States, England.

Induced disease: In cultivated strawberry, crinkling and chlorosis of leaves. At first, minute chlorotic flecks appear in young leaves. These flecks enlarge, and small necrotic spots may appear in their centers. Vein-clearing appears frequently. Affected foliage lighter and less uniformly green than normal. The variety Royal Sovereign may appear normal through carrying this virus.

Transmission: By aphid, *Myzus fragaefolii* Ckll. (= *Capitophorus fragariae* Theob.) (*APHIDIDAE*). By grafting. Not by inoculation of expressed juice.

Literature: Harris, Ann. Rept. East Malling Res. Sta. for 1936, 1937, 201-211, 212-221; *ibid.*, for 1937, 1938, 201-202; Harris and Hildebrand, Canad. Jour. Res., C, *15*, 1937, 252-280; Ogilvie et al., Ann. Rept. Long Ashton Res. Sta. for 1933, 1934, 96-97; Vaughan, Phytopath., *23*, 1933, 738-740; Zeller, Oregon Agr. Exp. Sta., Sta. Bull. 319, 1933; Zeller and Vaughan, Phytopath., *22*, 1932, 709-713.

49. **Marmor marginans** H. (*loc. cit.*, 79). From Latin *marginare*, to provide with a margin.

Common name: Strawberry yellow-edge virus.

Hosts: *ROSACEAE—Fragaria* hybrids, strawberries; *Fragaria californica* C. and S.; *F. chiloensis* Duch. (symptomless). Experimentally, also *Fragaria vesca* L.; *F. virginiana* Duch. (some clones appear to be immune to infection by runner inarching).

Geographical distribution: United States, England, France, New Zealand.

Induced disease: In strawberry, plant appears flat with outer zone of leaves more or less normal, central leaves dwarfed, yellow-edged, deficient in red pigmentation. The variety Premier may carry this virus without showing any obvious manifestation of disease.

Transmission: By aphid, *Myzus fragaefolii* Ckll. (*APHIDIDAE*). By grafting. Not by inoculation of expressed juice. Not through seeds from diseased plants.

Literature: Chamberlain, New Zealand Jour. Agr., *49*, 1934, 226-231; Harris, Jour. Pom. and Hort. Science, *11*, 1933, 56-76; Harris and Hildebrand, Canad. Jour. Res., C, *15*, 1937, 252-280; Hildebrand, *ibid.*, C, *19*, 1941, 225-233; Plakidas, Phytopath., *16*, 1926, 423-426; Jour. Agr. Res., *35*, 1927, 1057-1090.

50. **Marmor rubi** H. (Holmes, *loc. cit.*, 80; *Poecile rubi* McKinney, Jour. Washington Acad. Science, *34*, 1944, 148.) From Latin *rubus*, bramble bush.

Common name: Red-raspberry mosaic virus.

Hosts: *ROSACEAE—Rubus idaeus* L., red raspberry; *R. occidentalis* L., black raspberry.

Geographical distribution: United States.

Induced disease: In red raspberry, systemic chlorotic mottling, masked at high temperatures of summer. Foliage development delayed in spring. In some varieties, leaf petioles and cane tips die,

canes remain short and become rosetted.

Transmission: By aphids, principally *Amphorophora rubi* Kalt., but also *A. rubicola* Oestl. and *A. sensoriata* Mason (*APHIDIDAE*). Not by inoculation of expressed juice.

Literature: Bennett, Michigan Agr. Exp. Sta., Techn. Bull. 80, 1927; 125, 1932; Cooley, New York Agr. Exp. Sta. (Geneva), Bull. 675, 1936; Harris, Jour. Pom. and Hort. Science, *11*, 1933, 237–255; *17*, 1940, 318–343; Rankin, New York Agr. Exp. Sta., Geneva, Bull. 543, 1927; New York Agr. Exp. Sta., Geneva, Tech. Bull. 175, 1931.

51. **Marmor persicae** H. (Holmes, *loc. cit.*, 81; *Flavimacula persicae* McKinney, Jour. Washington Acad. Science, *34*, 1944, 149.) From New Latin *Persica*, former generic name of peach.

Common name: Peach-mosaic virus.

Hosts: *ROSACEAE—Prunus persica* (L.) Batsch, peach and nectarine, all tested varieties. Experimentally, also *P. armeniaca* L., apricot; *P. communis* Fritsch, almond; *P. domestica* L., plum and prune.

Insusceptible species: Attempts to infect sweet and sour cherries have thus far failed.

Geographical distribution: United States (Colorado, California, Utah, Oklahoma, Texas, New Mexico, Arizona).

Induced disease: In peach, short internodes in spring growth, sometimes breaking in flower pattern, chlorotic mottling and distortion of foliage early in season, masking of leaf symptoms or excision of affected areas of leaf lamina in midsummer; fruit small, irregular in shape, unsalable. Some peach varieties are less damaged than others, but all are thought to be equally susceptible to infection, and equally important as reservoirs of virus when infected. In almond, experimentally, symptomless infections; symptoms appear in some apricot and plum varieties when experimentally infected, not in others.

Transmission: By budding and other methods of grafting. Not by inoculation of expressed juice. Not through soil. No insect vector is known. Not through pollen or seed from diseased plants.

Thermal inactivation: Not demonstrated; virus not inactivated by temperatures effective in inactivating peach-yellows virus.

Literature: Bodine, Colorado Agr. Exp. Sta., Bull. 421, 1936; Bodine and Durrell, Phytopath., *31*, 1941, 322–333; Cation, *ibid.*, 24, 1934, 1380–1381; Christoff, Phytopath. Ztschr., *11*, 1938, 360–422; Cochran, California Cultivator, *87*, 1940, 164–165; Cochran and Hutchins, Phytopath., *28*, 1938, 890–892; Hutchins, Science, *76*, 1932, 123; Hutchins et al., U. S. Dept. Agr., Circ. 427, 1937, 48 pp.; Kunkel, Am. Jour. Bot., *23*, 1936, 683–686; Phytopath., *28*, 1938, 491–497; Thomas and Rawlins, Hilgardia, *12*, 1939, 623–644; Valleau, Kentucky Agr. Exp. Sta., Bull. 327, 1932, 89–103.

52. **Marmor astri** H. (*loc. cit.*, 83). From Latin *astrum*, star.

Common name: Peach asteroid-spot virus.

Host: *ROSACEAE—Prunus persica* (L.) Batsch, peach.

Geographical distribution: California.

Induced disease: In peach, discrete chlorotic lesions spreading along veins, forming star-like spots; developing leaves normal in appearance, becoming affected as they mature. Some chlorophyll retained in lesions as leaves turn yellow. Affected leaves shed early.

Transmission: By grafting. Not by inoculation of expressed juice. No insect vector is known.

Literature: Cochran and Smith, Phytopath., *28*, 1938, 278–281.

53. **Marmor rubiginosum** Reeves. (Phytopath., *30*, 1940, 789.) From Latin *rubiginosus*, rusty.

Common name: Cherry rusty-mottle virus.

Host: *ROSACEAE—Prunus avium* L., sweet cherry.

Geographical distribution: United States (Washington).

Induced disease: In sweet cherry, chlorotic mottling 4 to 5 weeks after full bloom, first on small basal leaves, later on all leaves. The older affected leaves develop autumnal colors and absciss, 30 to 70 per cent of the foliage being lost. The remaining foliage appears somewhat wilted, shows increased mottling, chlorotic spots, and areas becoming yellowish brown, appearing rusty. Blossoms normal. Fruits smaller than normal, insipid, not misshapen. Growth rate of tree reduced slightly.

Transmission: By grafting. Not by inoculation of expressed juice. No insect vector is known.

Literature: Reeves, Phytopath., *30*, 1940, 789 (Abst.); Jour. Agr. Res., *62*, 1941, 555–572 (see 566–567).

54. **Marmor cerasi** Zeller and Evans. (Phytopath., *31*, 1941, 467.) From Latin *cerasus*, cherry tree; originally spelled *cerasae*, by error.

Common name: Cherry mottle-leaf virus.

Hosts: *ROSACEAE—Prunus avium* L., sweet cherry; *P. emarginata* (Dougl.) Walp., wild cherry. Experimentally, also *P. cerasus* L. (tolerant) and *P. mahaleb* L. (tolerant).

Geographical distribution: United States (Washington, Oregon, Idaho, California) and Canada (British Columbia).

Induced disease: In sweet cherry, chlorotic mottling; leaves puckered, wrinkled, distorted, not perforated. Blossoms not affected. Fruit small, hard, insipid, uneven or delayed in ripening. Crop reduced. Branches shortened, tree eventually stunted.

Transmission: By budding. No insect vector is known. Not by the black cherry aphid, *Myzus cerasi* (F.) (*APHIDIDAE*). Not by inoculation of expressed juice.

Thermal inactivation: Not demonstrated; not at 46° C in 60 minutes nor at 49° C in 10 minutes in bud sticks.

Literature: Reeves, Washington State Hort. Assoc. Proc., *31*, 1935, 85–89; Jour. Agr. Res., *62*, 1941, 555–572; Zeller, Oregon State Hort. Soc. Report, 26, 1934, 92–95; Phytopath., *31*, 1941, 463–467.

55. **Marmor lineopictum** Cation (Phytopath., *31*, 1941, 1009.) From Latin *linea*, line, and *pictus*, ornamented.

Common names: Prunus line-pattern virus, peach line-pattern virus.

Hosts: *ROSACEAE—Prunus salicina* Lindl., Japanese plum; *P. mahaleb* L., Mahaleb cherry; *P. persica* (L.) Batsch, peach (= *Amygdalus persica* L.).

Geographical distribution: United States (Kentucky, Michigan, California, Ohio; perhaps widely distributed).

Induced disease: In peach and Mahaleb cherry, light-colored line patterns or faint chlorotic mottling, tending to become masked as leaf becomes old. In peach, affected foliage sometimes less glossy than normal. In *Prunus salicina*, no disease manifestations usually; rarely, chlorotic mottling on a few leaves.

Transmission: By grafting. No insect vector is known.

Literature: Berkeley, Div. of Bot. and Plant Path., Science Service, Dominion Dept. Agr., Ottawa, Canada, Publ. 679, 1941; Cation, Phytopath., *31*, 1941, 1004–1010; Thomas and Rawlins, Hilgardia, *12*, 1939, 623–644; Valleau, Kentucky Agr. Exp. Sta., Res. Bull. 327, 1932, 89–103.

56. **Marmor pallidolimbatus** Zeller and Milbrath. (In Handbook of Virus Diseases of Stone Fruits in North America, Michigan Agr. Exp. Sta., Miscell. Publ., May, 1942, 50; Phytopath., *32*, 1942, 635.) From Latin *pallidus*, pale, and *limbatus*, bordered.

Common name: Cherry banded-chlorosis virus.

Hosts: *ROSACEAE—Prunus serrulata* Lindl., flowering cherry; *P. avium* L., Mazzard cherry.

Geographical distribution: United States (Pacific Northwest).

Induced disease: In flowering cherry,

chlorotic bands surrounding discolored areas on leaves. In Mazzard cherry, dwarfing of whole plant, chlorotic bands on leaves.

Transmission: By budding, even in the absence of survival of inserted buds.

57. **Marmor nerviclarens** Zeller and Evans. (Phytopath., *31*, 1941, 467.) From Latin *nervus*, sinew or nerve, and *clarere*, to shine.

Common name: Cherry vein-clearing virus.

Hosts: *ROSACEAE—Prunus avium* L., sweet cherry. Perhaps also *P. serrulata* Lindl. and *P. domestica* L., on which symptoms similar to those induced by this virus have been observed.

Geographical distribution: United States (Oregon, Washington).

Induced disease: In sweet cherry, clearing of veins throughout each leaf or only in localized areas. Margins of leaves irregular, most indented where clearing of veins is most conspicuous. Elongated, elliptic, or slot-like perforations occur in some leaves. Affected leaves usually narrow. Enations occur as small blistered proliferations on lower side of main veins. Upper leaf surface silvery by reflected light. By midsummer, leaves droop and appear somewhat wilted; they may fold along the midvein. Internodes short; increased number of buds, spurs, or short branches at nodes; rosetting more pronounced on some branches than on others, mostly at end of year-old wood. In advanced disease, fruits pointed, small, flattened on suture side with swollen ridge along suture. Blossoms abnormally abundant, crop of fruit reduced or wanting.

Transmission: By grafting. Not demonstrated by inoculation of expressed juice. No insect vector is known.

58. **Marmor viticola** H. (*loc. cit.*, 83). From Latin *vitis*, vine, and *-cola*, inhabitant of.

Common name: Vine-mosaic virus.

Host: *VITACEAE—Vitis vinifera* L., grape.

Geographical distribution: France, Italy, Bulgaria, Czechoslovakia.

Induced disease: In grape, various modifications of systemic chlorotic mottling, and red pigmentation of parts of leaves with subsequent drying and dropping out of affected spots. Leaves deformed, crimped between main veins. Growth restricted.

Transmission: By inoculation of expressed juice and by pruning.

Literature: Blattný, Vinařský obzor., *25*, 1931, 4–5 (Cent. f. Bakt., II Abt., *84*, 1931, 464); Ochrana Rostlin, *13*, 1933, 104–105 (Rev. Appl. Mycol., *13*, 1934, 421); Gigante, Boll. Staz. Pat. Veg. Roma, n. s. *17*, 1937, 169–192 (Rev. Appl. Mycol., *17*, 1938, 221); Pantanelli, Malpighia, *24*, 1911, 497–523; *25*, 1912, 17–46; Stranak, II Congr. Intern. Path. Comp. Paris, 1931, 367–378; Ochrana Rostlin, *11*, 1931, 89–98 (Rev. Appl. Mycol., *11*, 1932, 280); Vielwerth, Ochrana Rostlin, *13*, 1933, 83–90 (Rev. Appl. Mycol., *13*, 1934, 421–422).

59. **Marmor santali** H. (*loc. cit.*, 94). From New Latin, *Santalum*, generic name of sandal.

Common name: Sandal leaf-curl virus.

Host: *SANTALACEAE—Santalum album* L., sandal.

Geographical distribution: India.

Induced disease: In sandal, leaves small, curled, wrinkled, thickened, brittle, abscissing. Systemic chlorotic mottling. Internode length normal. Infected twigs produce both flowers and fruits.

Transmission: By ring bark-grafts. Not by inoculation of expressed juice. No insect vector is known.

Literature: Venkata Rao, Mysore Sandal Spike Invest. Comm., Bull. 3, 1933.

60. **Marmor secretum** Bennett. (Phytopath., *34*, 1944, 88). From Latin *secretus*, hidden.

Common name: Dodder latent-mosaic virus.

Hosts: *CONVOLVULACEAE—Cuscuta californica* Choisy, dodder. Experi-

mentally, also *CHENOPODIACEAE—Beta vulgaris* L., sugar beet; *Chenopodium album* L., lamb's quarters; *C. murale* L., sowbane. *CONVOLVULACEAE—Cuscuta campestris* Yuncker; *C. subinclusa* Dur. and Hilg. *CRUCIFERAE—Brassica incana* (L.) F. W. Schultz, mustard (tolerant). *CUCURBITACEAE—Cucumis melo* L., cantaloupe. *PHYTOLACCACEAE—Phytolacca americana* L., pokeweed. *PLANTAGINACEAE—Plantago major* L., plantain. *POLYGONACEAE—Fagopyrum esculentum* Moench, buckwheat; *Polygonum pennsylvanicum* L., knotweed. *PRIMULACEAE—Samolus floribundus* HBK., water pimpernel. *SOLANACEAE—Lycopersicon esculentum* Mill., tomato; *Nicotiana glauca* Graham (tolerant); *N. palmeri* Gray; *N. rustica* L. (tolerant); *N. tabacum* L. (tolerant); *Solanum tuberosum* L., potato. *UMBELLIFERAE—Apium graveolens* L., celery.

Insusceptible species: *COMPOSITAE—Helianthus annuus* L., sunflower; *Lactuca sativa* L., lettuce. *CRUCIFERAE—Brassica oleracea* L., cabbage. *POLYGONACEAE—Eriogonum fasciculatum* Benth., California buckwheat. *SCROPHULARIACEAE—Verbascum thapsus* L., mullein. *SOLANACEAE—Atropa belladonna* L., belladonna.

Geographical distribution: United States (California).

Induced disease: In dodder, no symptoms. In sugar beet, experimentally, temporary systemic chlorotic spotting; occasional faded areas in leaves in subsequent chronic stage of disease. In cantaloupe, experimentally, chlorotic spotting, reduction in leaf size, death of some leaves, stunting of plant; melons small and of poor quality. In celery, experimentally, systemic chlorosis followed by dwarfing and mottling with subsequent apparent recovery.

Transmission: By dodder, *Cuscuta californica*, *C. campestris*, and *C. subinclusa*. By inoculation of extracted juice to some, but not to other, host plants; *Phytolacca americana* is readily infected by rubbing methods in the presence of a small amount of abrasive, and develops numerous necrotic primary lesions that serve for quantitative estimation of concentration of virus in inoculum. Through seeds from infected plants of dodder, *Cuscuta campestris*; not through seeds from diseased cantaloupe, buckwheat, or pokeweed plants. No insect vector is known.

Thermal inactivation: At 56 to 60° C in 10 minutes.

Filterability: Passes celite and Berkefeld N and W filters.

Other properties: Infective in dilutions to 1:3000. Inactivated by drying and by storage in expressed pokeweed juice, within 48 hours.

61. **Marmor pelargonii** *spec. nov.* From New Latin *Pelargonium*, generic name of common geranium.

Common names: Pelargonium leaf-curl virus; virus of dropsy or Kräuselkrankheit of geranium.

Host: *GERANIACEAE—Pelargonium hortorum* Bailey, geranium.

Induced disease: In geranium, circular or irregular chlorotic spots, sometimes stellate or dendritic, ½ to 5 mm in diameter, centers becoming brown with chlorotic border; severely affected leaves become yellow and drop; spotted leaves ruffled, crinkled, malformed, small, sometimes puckered and splitting. Petioles and stems show corky, raised, necrotic streaks; tops may die. Disease most severe in spring, inconspicuous in summer.

Transmission: By grafting. Not by inoculation of expressed juice nor by use of knife to prepare cuttings for propagation. Not through seed. No insect vector is known.

Literature: Berkeley, Canad. Hort. and Home Mag., *1938*, 1938, 1–4; Blattný, Ochrana Rostlin, *13*, 1933, 145 (Rev. Appl. Mycol., *13*, 1934, 378–379); Bremer, Blumen-u. Pflanzenbau, *48*, 1933, 32–33 (Rev. Appl. Mycol., *12*, 1933, 514); Halstead, New Jersey Agr. Exp. Sta., Rept. 14, 1893, 432–433; Jones, Washington Agr. Exp. Sta., Bull. 390, 1940;

Laubert, Gartenwelt, *31*, 1927, 391; Pape, *ibid.*, *26*, 1927, 329–331; *32*, 1928, 116–117; Pethybridge and Smith, Gard. Chron., *92*, 1932, 378–379; Schmidt, Gartenwelt, *81*, 1932, 40; Seeliger, Nachrichtenbl. Deutsch. Pflanzenschutzdienst, *6*, 1926, 63–64; Tuimann, Gartenwelt, *31*, 1927, 375–376; Verplancke, Bul. Cl. Sci. Acad. Roy. de Belgique, Ser. 5, *18*, 1932, 269–281 (Rev. Appl. Mycol., *11*, 1932, 649–650).

62. **Marmor angliae** H. (*loc. cit.*, 48). From Latin *Anglia*, England.

Common name: Potato-paracrinkle virus.

Hosts: *SOLANACEAE—Solanum tuberosum* L., potato. Experimentally, also *Datura stramonium* L., Jimson weed.

Insusceptible species: *SOLANACEAE—Nicotiana tabacum* L., tobacco.

Geographical distribution: England.

Induced disease: In potato, masked in all plants of the variety King Edward. Chlorotic mottling with some necrosis in the varieties Arran Victory and Arran Chief. Chlorotic mottling only in Arran Comrade, Majestic, and Great Scot potatoes. Two varieties, Sharpe's Express and Epicure, are said to be resistant.

Transmission: By grafts. Not by inoculation of expressed juice. No insect vector is known.

Literature: Dykstra, Phytopath., *26*, 1936, 597–606; Salaman and Le Pelley, Proc. Roy. Soc. London, Ser. B, *106*, 1930, 140–175.

63. **Marmor aevi** *spec. nov.* From Latin *aevum*, old age, in reference to the obvious involvement of old, but not of young, delphinium leaves.

Common name: Celery-calico virus.

Hosts: *CUCURBITACEAE—Cucumis sativus* L., cucumber; *C. melo* L., cantaloupe; *Cucurbita pepo* L., summer crookneck squash. *RANUNCULACEAE—Delphinium chinensis*; *D. formosum*, hardy larkspur; *D. grandiflorum; D. parryi; D. zalil. SOLANACEAE—Lycopersicon esculentum* Mill., tomato. *UMBELLIFERAE—Apium graveolens* L., celery. Experimentally, also *SOLANACEAE—Nicotiana tabacum* L., tobacco; *Petunia hybrida* Vilm., petunia. *VIOLACEAE—Viola cornuta* L.

Geographical distribution: United States.

Induced disease: In celery, clearing of veins, puckering and downward cupping of younger leaves, green islands of tissue in lemon-yellow areas of outer leaves, green and yellow zigzag bands on leaflets. In delphinium, basal and middle leaves with pale-orange, amber, or lemon-yellow areas; younger leaves normal green; chlorotic ring and line patterns.

Transmission: By inoculation of expressed juice in the presence of finely powdered carborundum. By aphids: *Aphis apigraveolens* Essig, celery leaf aphid; *A. apii* Theob., celery aphid; *A. ferruginea-striata* Essig, rusty-banded aphid; *A. gossypii* Glov., cotton aphid; *A. middletonii* Thomas, erigeron root aphid; *Myzus circumflexus* (Buckt.), lily aphid; *M. convolvuli* (Kalt.), foxglove aphid; *M. persicae* (Sulz.), green peach aphid; *Rhopalosiphum melliferum* (Hottes), honeysuckle aphid (*APHIDIDAE*).

Literature: Severin, Hilgardia, *14*, 1942, 441–464; Severin and Freitag, Phytopath., *25*, 1935, 891 (Abst.); Hilgardia, *11*, 1938, 493–558.

64. **Marmor raphani** *spec. nov.* From Latin *raphanus*, radish.

Common name: Radish-mosaic virus.

Hosts: *CRUCIFERAE—Raphanus sativus* L., radish. Experimentally, also *CRUCIFERAE—Brassica oleracea* L.; *B. nigra* (L.) Koch; *B. alba* (L.) Boiss; *B. arvensis* (L.) Ktze.; *B. pe-tsai* Bailey; *B. juncea* (L.) Coss; *B. rapa* L.; *B. adpressa* Boiss; *Capsella bursa-pastoris* (L.) Medic.; *Malcomia maritima* R. Br.; *M. bicornis* DC. *CHENOPODIACEAE—Chenopodium album* L.; *C. murale* L.; *Spinacia oleracea* L. *RANUNCULACEAE—Delphinium ajacis* L. *SOLANACEAE—Nicotiana glutinosa* L.; *N.*

langsdorffii Weinm.; *N. rustica* L.; *N. tabacum* L.

Geographical distribution: United States (California).

Induced disease: In radish, systemic chlorotic spotting followed by chlorotic mottling of foliage; little or no leaf distortion; plants not stunted.

Transmission: By inoculation of expressed juice. No insect vector is known; not by the cabbage aphid, *Brevicoryne brassicae* (L.); the false cabbage aphid, *Lipaphis pseudobrassicae* (Davis); or the green peach aphid, *Myzus persicae* (Sulz.) (*APHIDIDAE*). Not through seeds from diseased radish plants.

Thermal inactivation: At 65 to 68° C in 10 minutes.

Literature: Tompkins, Jour. Agr. Res., *58*, 1939, 119–130.

65. **Marmor primulae** *spec. nov.* From New Latin *Primula*, generic name of primrose.

Common name: Primrose-mosaic virus.

Hosts: *PRIMULACEAE—Primula obconica* Hance. Experimentally, also *P. malacoides* Franch. and *P. sinensis* Lindl.

Insusceptible species: *BEGONIACEAE—Begonia semperflorens* Link and Otto. *BORAGINACEAE—Myosotis alpestris* Schmidt. *CAMPANULACEAE—Campanula medium* L. *CARYOPHYLLACEAE—Dianthus barbatus* L. *CHENOPODIACEAE—Spinacia oleracea* L. *COMPOSITAE—Bellis perennis* L.; *Callistephus chinensis* Nees; *Gerbera jamesonii* Hook.; *Lactuca sativa* L.; *Senecio cruentus* DC.; *Tagetes patula* L. *CRUCIFERAE—Brassica oleracea* L.; *B. pe-tsai* Bailey; *B. rapa* L.; *Matthiola incana* R. Br.; *Raphanus sativus* L. *CUCURBITACEAE—Cucumis sativus* L.; *Cucurbita pepo* L. *EUPHORBIACEAE—Ricinus communis* L. *GRAMINEAE—Zea mays* L. *LEGUMINOSAE—Pisum sativum* L.; *Vicia faba* L.; *Vigna sinensis* (Torner) Savi. *LOBELIACEAE—Lobelia hybrida* Hort. *PAPAVERACEAE—Papaver orientale* L. *PRIMULACEAE—Anagallis arvensis* L.; *Cyclamen indicum* L.; *Primula auricula* L.; *P. veris* L. *RANUNCULACEAE—Anemone coronaria* L.; *Delphinium cultorum* Voss; *Ranunculus asiaticus* L. *RESEDACEAE—Reseda odorata* L. *ROSACEAE—Geum chiloense* Balb. *SCROPHULARIACEAE—Antirrhinum majus* L.; *Pentstemon barbatus* Nutt. *SOLANACEAE—Capsicum frutescens* L.; *Datura stramonium* L.; *Lycopersicon esculentum* Mill.; *Nicotiana glutinosa* L.; *N. tabacum* L.; *Solanum tuberosum* L. *TROPAEOLACEAE—Tropaeolum majus* L. *UMBELLIFERAE—Apium graveolens* L. *VERBENACEAE—Verbena hybrida* Voss. *VIOLACEAE—Viola tricolor* L.

Geographical distribution: United States (California).

Induced disease: In *Primula obconica*, chlorosis, stunting, rugosity with upward, or occasionally downward, cupping of leaves. Petioles and peduncles shortened; flowers reduced in size, broken in color (white-streaked). Leaves coarsely mottled with yellow-green, leaving green islands; tips of leaves sometimes narrowed.

Transmission: By inoculation of expressed juice, in the presence of 600-mesh powdered carborundum. Not by aphids, *Myzus persicae* (Sulz.) and *M. circumflexus* (Buckt.) (*APHIDIDAE*). No insect vector is known. Probably not through seeds.

Thermal inactivation: At 50° C, not 48° C, in 10 minutes.

Other properties: Infective after 24, not 48, hours *in vitro*. Infective after 1:10 dilution.

Literature: Tompkins and Middleton, Jour. Agr. Res., *63*, 1941, 671–679.

66. **Marmor caricae** (Condit and Horne) *comb. nov.* (*Ficivir caricae* Condit and Horne, Phytopath., *31*, 1941, 563.) From Latin *carica*, a kind of dried fig.

Common name: Fig-mosaic virus.

Hosts: *MORACEAE—Ficus carica* L.,

fig; *F. altissima* Blume; *F. krishna*; and *F. tsiela* Roxb.

Geographical distribution: United States (California, Texas), England, Puerto Rico, China, New South Wales, Western Australia.

Induced disease: In fig, systemic chlorotic spotting and mottling of foliage; some severe leaf distortion. Fruits sometimes affected, bearing light circular areas, rusty spots, being deformed or dropped prematurely. Necrotic lesions on profichi of Samson caprifigs also have been attributed to action of this virus.

Transmission: By budding. No insect vector is known; mites have been suspected as possible vectors.

Literature: Condit and Horne, Phytopath., *23*, 1933, 887–896; *31*, 1941, 561–563; *33*, 1943, 719–723; Ho and Li, Lingnan Science Jour., *15*, 1936, 69–70; Pittman, W. Austral. Dept. Agr. Jour., *12*, 1935 196.

67. **Marmor italicum** (Fawcett) *comb. nov.* (*Citrivir italicum* Fawcett, Phytopath., *31*, 1941, 357.) Specific epithet meaning "pertaining to Italy."

Common name: Citrus infectious-mottling virus.

Host: *RUTACEAE—Citrus aurantium* L., sour orange.

Geographical distribution: Italy.

Induced disease: In sour orange, white, pale green, or yellow irregular areas in leaves, leaving narrow green bands along midrib; leaves blistered and distorted.

Transmission: The aphid, *Toxoptera aurantii* (Phytopath., *24*, 1934, 661), has been suspected as vector.

Literature: Fawcett, Phytopath., *31*, 1941, 356–357; Petri, Bol. Staz. Pat. Veg. Roma, n. s. *11*, 1931, 105–114.

Note: Several additional species were described too late for complete systematic treatment here. They are plain's wheat mosaic virus, **Marmor campestre** McKinney (Jour. Washington Acad. Sci., *34*, 1944, 324) with varieties *typicum* McKinney and *galbinum* McKinney, respectively causing light-green mosaic and severe yellow mosaic of wheat in Kansas; wheat streak-mosaic virus, **Marmor virgatum** McKinney (*ibid.*, *34*, 1944, 324) with varieties *typicum* McKinney and *viride* McKinney (*ibid.*, *34*, 1944, 325), respectively causing yellow streak-mosaic and green streak-mosaic of wheat in Kansas; Agropyron-mosaic virus, **Marmor agropyri** McKinney (*ibid.*, *34*, 1944, 326), with varieties *typicum* McKinney and *flavum* McKinney, respectively causing green-mosaic mottling and yellow-mosaic mottling in the grass *Agropyron repens* (L.) Beauv. in Virginia; also a virus, **Flavimacula ipomeae** Doolittle and Harter (Phytopath., *35*, 1945, 703), causing feathery mottle of sweet potato in Maryland [see *Marmor persicae* for treatment of a virus that was assigned as type of *Flavimacula* McKinney (Jour. Washington Acad. Sci., *34*, 1944, 149), a genus originally differentiated from *Marmor* as containing viruses not yet inoculable save by tissue union; a natural group of viruses may be represented but their characteristics and affiliations seem not yet clear].

Genus II. **Acrogenus** *Holmes.*

(*Loc. cit.*, 110.)

Viruses of the Spindle-Tuber Group, inducing diseases characterized by abnormal growth habit of host plants without chlorotic or necrotic spotting, systemic chlorosis, witches'-broom formation, or production of galls. Generic name from Greek, meaning point- or peak-producing, in reference to shape of potatoes affected by potato spindle-tuber virus.

The type species is *Acrogenus solani* Holmes.

Key to the species of genus **Acrogenus.**

I. Infecting potato.
1. *Acrogenus solani.*

II. Infecting black currant.
2. *Acrogenus ribis.*

1. **Acrogenus solani** Holmes. (Handb. Phytopath. Viruses, 1939, 111.) From New Latin *Solanum*, generic name of potato.

Common names: Potato spindle-tuber virus, potato spindling-tuber virus, potato marginal leaf-roll virus.

Host: *SOLANACEAE—Solanum tuberosum* L., potato.

Geographical distribution: United States and Canada.

Induced disease: Plants erect, stiff, spindly, lacking vigor. Leaves small, erect, darker green than normal. Petioles sometimes slender, brittle. Tubers long, cylindrical, irregular in shape, tapered at ends, smooth and tender-skinned, of softer than normal flesh in spring. Eyes of tuber conspicuous.

Transmission: By inoculation of expressed juice; by use of contaminated knife in cutting successive tubers before planting; by contacts of freshly cut seed pieces. By aphids, *Myzus persicae* (Sulz.) and *Macrosiphum solanifolii* Ashm. (= *M. gei* Koch) (*APHIDIDAE*). Also by certain leaf-eating insects.

Thermal inactivation: At 60 to 65° C in 10 minutes (in tuber tissues).

Literature: Bald et al., Phytopath., *31*, 1941, 181–186; Folsom, Maine Agr. Exp. Sta., Orono, Bull. 312, 1923; Goss, Phytopath., *16*, 1926, 233, 299–303; *18*, 1928, 445–448; Nebraska Agr. Exp. Sta., Res. Bull. *47*, 1930; *53*, 1931; Jaczewski, La Défense des Plantes, Leningrad, *4*, 1927, 62–77 (Rev. Appl. Mycol., *6*, 1927, 572–573, Abst.); McLeod, Canad. Exp. Farms, Div. Bot., Rpt. for 1926, 1927.

Strains: A strain causing unmottled curly dwarf of potato has been given a varietal name to distinguish it from the type, var. *vulgaris* H. (*loc. cit.*, 111):

1a. *Acrogenus solani* var. *severus* H. (*loc. cit.*, 112). Inducing symptoms in potato on the whole more severe than those caused by the type strain.

Common name: Unmottled curly-dwarf strain of potato spindle-tuber virus. (Goss, Nebraska Agr. Exp. Sta., Res. Bull. 47, 1930; *53*, 1931; Schultz and Folsom, Jour. Agr. Res., *25*, 1923, 43–118.)

2. **Acrogenus ribis** H. (*loc. cit.*, 112). From Latin *ribes*, currant.

Common name: Black-currant reversion-disease virus.

Host: *SAXIFRAGACEAE—Ribes nigrum* L., European black currant.

Geographical distribution: British Isles.

Induced disease: In European black currant, leaves abnormally narrow and flat, small veins few. Flowers sometimes nearly transparent, smooth, sepals brightly colored beneath. Flowers and small fruits fall. Stems less woody than normal, with tendency to excessive gum production.

Transmission: By grafting. By big-bud mite, *Eriophyes ribis* (*ERIOPHYIDAE*). Not by inoculation of expressed juice. Not through soil. Not through seeds from diseased plants.

Literature: Amos and Hatton, Jour. Pom. and Hort. Science, *6*, 1926, 167–183; Amos et al., in East Malling Res. Sta., 15th Ann. Rpt., 1928, 43–46; Lee, Ann. Appl. Biol., *9*, 1935, 49–68.

Genus III. Corium *Holmes.*

(*Loc. cit.*, 119.)

Viruses of the Leaf-Roll Group, inducing diseases usually characterized by thicken-

ing and rolling of leaves. Foliage leathery. Sometimes conspicuous phloem necrosis. Generic name from Latin *corium*, leather.

The type species is *Corium solani* Holmes.

Key to the species of genus **Corium.**

I. Infecting potato.
   1. *Corium solani.*

II. Infecting beet.
   2. *Corium betae.*

III. Infecting raspberry.
   3. *Corium rubi.*
   4. *Corium ruborum.*

1. **Corium solani** Holmes. (Handb. Phytopath. Viruses, 1939, 120.) From New Latin *Solanum*, generic name of potato.

Common name: Potato leaf-roll virus.

Hosts: *SOLANACEAE—Solanum tuberosum* L., potato. Experimentally, also other solanaceous species, *Datura stramonium* L., Jimson weed; *Lycopersicon esculentum* Mill., tomato; *Solanum dulcamara* L., bittersweet; *S. villosum.*

Insusceptible species: *CHENOPODIACEAE—Beta vulgaris* L., beet.

Geographical distribution: North America, France, British Isles; probably wherever potatoes are grown.

Induced disease: In potato, leaves thick, rigid, leathery, and rolled, their starch content excessive. Plants dwarfed. Tubers few, small, crisp. Tubers of some varieties show conspicuous phloem necrosis, germinate with spindling sprouts.

Transmission: By aphid, *Myzus persicae* (Sulz.) (*APHIDIDAE*), with incubation period of 24 to 48 hours. Also by *Myzus convolvuli* (Kalt.) (= *M. pseudosolani* Theob.), *M. circumflexus* (Buckt.), *Macrosiphum solanifolii* Ashm., and *Aphis abbreviata* Patch (*APHIDIDAE*). By grafting. Not by inoculation of expressed juice.

Literature: Artschwager, Jour. Agr. Res., *15*, 1918, 559–570; *24*, 1923, 237–245; Dykstra, *ibid.*, *47*, 1933, 17–32; Elze, Phytopath., *21*, 1931, 675–686; Folsom, Maine Agr. Exp. Sta., Bull. 297, 1921, 37–52; *410*, 1942, 215–250; Murphy, Scient. Proc. Roy. Dublin Soc., *17*, 1923, 163–184; Murphy and M'Kay, *ibid.*, *19*, 1929, 341–353; Schultz and Folsom, Jour. Agr. Res., *21*, 1921, 47–80; Smith, Ann. Appl. Biol., *16*, 1929, 209–229; *18*, 1931, 141–157; Stevenson et al., Am. Potato Jour., *20*, 1943, 1–10.

2. **Corium betae** *spec. nov.* From Latin *beta*, beet.

Common names: Sugar-beet yellows virus, beet-yellows virus, jaunisse virus, vergelingsziekte virus.

Hosts: *CHENOPODIACEAE—Beta vulgaris* L., beet; *B. maritima* L.; *B. cicla*; *Atriplex hortensis* L.; *A. sibirica* L.; *Chenopodium album* L., lamb's quarters; *Spinacia oleracea* L., spinach. *AMARANTHACEAE —Amaranthus retroflexus* L.

Insusceptible species: *SOLANACEAE—Solanum tuberosum* L., potato; all other tested solanaceous species.

Geographical distribution: Belgium, Netherlands, Denmark, England; perhaps Germany and the United States.

Induced disease: In beet, young leaves little affected; older leaves yellow, brittle, short, thick, containing excessive amounts of carbohydrates; necrosis in secondary phloem. In spinach, yellowing, necrosis between veins on old leaves.

Transmission: Not by inoculation of expressed juice. By aphids, *Myzus persicae* (Sulz.), *Aphis fabae* Scop., *Macrosiphum solanifolii* Ashm., and *Aulacor-*

thum solani Kalt. (*APHIDIDAE*); virus is not transmitted by these aphids to their descendants. Not through seeds of beet. Virus overwinters in beets stored for subsequent use in seed production.

Serological relationships: Specific precipitating antiserum effective with crude sap of diseased, not healthy, plants and with sap of diseased plants after passage through a Chamberland L_1, not L_3, filter candle; ineffective with sap from beet plants suffering from mosaic.

Thermal inactivation: Virus heated to about 52°C no longer precipitates with specific antiserum.

Literature: Kleczkowski and Watson, Ann. Appl. Biol., *31*, 1944, 116–120; Petherbridge and Stirrup, London, Ministry Agr. and Fisheries, Bull. *93*, 1935; Quanjer and Roland, Tijdschr. Plantenziekten, *42*, 1936, 45–70; Roland, *ibid.*, *45*, 1939, 1–22, 181–203; Schreven, Meded. Inst. voor Suikerbietenteelt, Bergen op Zoom, *6*, 1936, 1; Watson, Proc. Roy. Soc. London, Ser. B, *128*, 1940, 535–552; Ann. Appl. Biol., *29*, 1942, 358–365.

3. **Corium rubi** H. (*loc. cit.*, 121). From New Latin *Rubus*, generic name of raspberry, from Latin *rubus*, bramble bush.

Common name: Raspberry leaf-curl virus.

Host: *ROSACEAE—Rubus idaeus* L., red raspberry.

Insusceptible species: *ROSACEAE—Rubus occidentalis* L., black raspberry; *R. neglectus* Peck, purple raspberry.

Geographical distribution: United States, not in England.

Induced disease: In red raspberry, veins retarded in growth, causing downward curling of leaf margins and crinkling of leaf lamina. Foliage dark green, dry in appearance, not wilting readily. In late summer, leaves bronzed, leaf surface glistening. Diseased canes easily winter-killed. Berries small and poor. The English variety Lloyd George is intolerant of the disease and is killed.

Transmission: By aphid, *Aphis rubicola* Oestl. (= *A. rubiphila* Patch) (*APHIDIDAE*). Not by inoculation of expressed juice.

Literature: Bennett, Michigan Agr. Exp. Sta., Tech. Bull. 80, 1927; Phytopath., *20*, 1930, 787–802, Harris, East Malling Res. Sta., Ann. Rpt. for 1934, 1935; Rankin, New York Agr. Exp. Sta., Geneva, Tech. Bull. 175, 1931.

Strains: A strain differing from the type, var. *alpha* H. (*loc. cit.*, 121), has been given a varietal name derived from its common name, raspberry beta-curl virus:

3a. *Corium rubi* var. *beta* H. (*loc. cit.*, 122). Infecting black and purple raspberries, as well as the red raspberry, which alone is susceptible to the type strain, raspberry alpha-curl virus. (Bennett, Phytopath., *20*, 1930, 787–802.)

4. **Corium ruborum** (Zeller and Braun) *comb. nov.* (*Minuor ruborum* Zeller and Braun, Phytopath., *33*, 1943, 161.) From Latin *rubus*, bramble bush.

Common name: Raspberry decline-disease virus.

Host: *ROSACEAE—Rubus idaeus* L., red raspberry.

Geographical distribution: United States (Oregon).

Induced disease: In Cuthbert raspberry, shoots retarded in spring, reddish; leaves in autumn rolled downward, fluted along veins, less green than normal between veins, slightly bronzed along margins and crests between veins. Internodes shortened near tips of canes. Affected canes small, weak, not hardy in winter. Small roots and feeder rootlets fewer than in healthy plants. Disease progressive over about three years. Fruits small, irregular, tending to be globose, crumbly when ripe, worthless.

Transmission: By grafting. No insect vector is known.

Genus IV. **Nanus** *Holmes.*

(*Loc. cit.*, 123.)

Viruses of the Dwarf-Disease Group, inducing diseases characterized by dwarfing of host plants or by growth of adventitious shoots with short internodes; chlorotic mottling absent. Generic name from Latin *nanus*, dwarf.

The type species is *Nanus loganobacci* Holmes.

Key to the species of genus **Nanus.**

I. Infecting rosaceous plants.

A. In loganberry and Phenomenal berry.
   1. *Nanus loganobacci.*

B. In black raspberry.
   2. *Nanus orientalis.*

C. In peach.
   3. *Nanus mirabilis.*

D. In ocean spray.
   4. *Nanus holodisci.*

E. In strawberry.
   5. *Nanus fragariae.*
   6. *Nanus cupuliformans.*

F. In prune and plum.
   7. *Nanus pruni.*

II. Infecting graminaceous plants.

A. In sugar cane.
   8. *Nanus sacchari.*

1. **Nanus loganobacci** Holmes. (Handb. Phytopath. Viruses, 1939, 124.)

From New Latin *loganobaccus*, specific epithet of loganberry, *Rubus loganobaccus* Bailey.

Common name: Loganberry-dwarf virus.

Hosts: *ROSACEAE—Rubus loganobaccus* Bailey, loganberry and Phenomenal berry.

Geographical distribution: United States (Oregon, Washington, and California).

Induced disease: In Phenomenal berry, leaves small, obovate, rigid, new canes short, spindly. In young plants, some necrosis along and between veins, leaves crinkled, finer veins chlorotic. Stems not streaked or mottled, normal in color. In late stages, canes very short, internodes short. Sepals and petals of flowers small. Fruit of fair size, but druplets ripen unevenly and tend to fall apart when picked. Loganberry is less susceptible than the Phenomenal berry but is similarly affected.

Transmission: By aphid, *Capitophorus tetrahodus* (*APHIDIDAE*). Not by inoculation of expressed juice.

Literature: Zeller, Phytopath., *15*, 1925, 732 (Abst.); *17*, 1927, 629–648.

2. **Nanus orientalis** H. (*loc. cit.*, 124).

From Latin *orientalis*, eastern.

Common names: Raspberry-streak virus, raspberry eastern blue-stem virus, raspberry rosette virus.

Host: *ROSACEAE—Rubus occidentalis* L., black raspberry.

Insusceptible species: *ROSACEAE—Rubus idaeus* L., red raspberry; *R. phoenicolasius* Maxim., Japanese wineberry.

Geographical distribution: United States.

Induced disease: In black raspberry, plants stunted, becoming smaller in successive seasons; leaves usually curled, close together on canes, dark green, often twisted so as to be upside down. New canes show bluish violet dots, spots, or stripes near their bases and sometimes also on branches or on fruiting spurs.

Fruit inferior in size, quality, and quantity. Plants live only 2 or 3 years after infection on the average.

Strains: A strain of this virus is believed responsible for mild streak of black raspberries, in which purple to violet, greenish brown, or bluish streaks on canes are narrowly linear or elliptical in form and often very faint; when the bloom is rubbed off, the lesions appear as though watersoaked and discolored. Leaves are slightly curled, their veins cleared. Fruits are dry and dull in lustre, even while still red, and of poor flavor when ripe.

Literature: Bennett, Michigan Agr. Exp. Sta., Tech. Bull. 80, 1927; Wilcox U. S. Dept. Agr., Dept. Circ. 227, 1923; Woods and Haut, U. S. Dept. Agr., Plant Dis. Rpt., *24*, 1940, 338–340.

3. **Nanus mirabilis** H. (*loc. cit.*, 126). From Latin *mirabilis*, strange.

Common name: Peach phony-disease virus.

Hosts: *ROSACEAE—Prunus persica* (L.) Batsch, peach. Experimentally, also other *Prunus* species.

Geographical distribution: United States (Georgia, Alabama, Florida; sparsely als› in Mississippi, Tennessee, South Carolina, Louisiana, Texas, Arkansas, Missouri).

Induced disease: In peach, tree dwarfed, foliage abnormally green, fruit small; flecks in wood, especially in roots; sections of roots show characteristic well-distributed purple spots after 3 to 5 minutes of treatment in 25 cc absolute methyl alcohol acidulated by the addition of 1 to 5 drops of concentrated, chemically pure hydrochloric acid.

Transmission: By root grafting, except by root-bark patch grafts, which are ineffective. Budding and grafting with parts of stem fail to transmit this virus.

Thermal inactivation: At 48° C in about 40 minutes in roots.

Literature: Hutchins, Georgia State Entomol. Bull., 78, 1933; Phytopath., *29*, 1939, 12 (Abst.); Hutchins and Rue, *ibid.*, *29*, 1939, 12 (Abst.).

4. **Nanus holodisci** H. (*loc. cit.*, 127). From New Latin *Holodiscus*, generic name of ocean spray.

Common name: Ocean-spray witches'-broom virus.

Host: *ROSACEAE—Holodiscus discolor* Max., ocean spray.

Geographical distribution: United States (Oregon and Washington).

Induced disease: In ocean-spray, diseased branches form clusters of thin wiry shoots with abnormally short internodes and crowded small leaves. Laterals numerous and more than normally branched. Bronzy red color acquired early by affected foliage.

Transmission: By aphid, *Aphis spiraeae* Schout. (*APHIDIDAE*). By grafting. Not demonstrated by inoculation of expressed juice.

Literature: Zeller, Phytopath., *21*, 1931, 923–925.

5. **Nanus fragariae** H. (Holmes, *loc. cit.*, 128; *Blastogenus fragariae* McKinney, Jour. Washington Acad. Science, *34*, 1944, 151.) From New Latin *Fragaria*, generic name of strawberry.

Common name: Strawberry witches'-broom virus.

Host: *ROSACEAE—Fragaria chiloensis* Duch. var. *ananassa* Bailey, cultivated strawberry.

Geographical distribution: United States (western Oregon).

Induced disease: In strawberry, leaves numerous, light in color, with spindly petioles, margins of leaflets bent down, runners shortened, plants dwarfed; flower stalks spindly and unfruitful; root systems normal and well developed.

Transmission: By aphis, *Myzus fragaefolii* Ckll. (*APHIDIDAE*). Not demonstrated by inoculation of expressed juice.

Literature: Zeller, Phytopath., *17*, 1927, 329–335.

6. **Nanus cupuliformans** Zeller and Weaver. (Phytopath., *31*, 1941, 851.) From diminutive of Latin *cupa*, tub, and participal from Latin *formare*, to form.

Common name: Strawberry-stunt virus.

Host: *ROSACEAE—Fragaria chiloensis* Duch. var. *ananassa* Bailey, cultivated strawberry.

Geographical distribution: United States (Oregon, Washington).

Induced disease: In strawberry, little if any reduction in chlorophyll, plants erect but short; leaves at first folded, later open, dull in lustre, with papery rattle when brushed by hand, leaflets cupped or with margins turned down, midveins tortuous; petioles ½ to ⅔ normal length; fruits small, usually hard and seedy; roots normal in appearance.

Transmission: By strawberry-leaf aphid, *Capitophorus fragaefolii* (*APHIDIDAE*). By grafting. Not by inoculation of expressed juice.

7. **Nanus pruni** H. (*loc. cit.*, 128). From New Latin *Prunus*, generic name of prune, from Latin *prunus*, plum tree.

Common name: Prune-dwarf virus.

Hosts: *ROSACEAE—Prunus domestica* L., prune and plum; var. *insititia* Bailey, the Damson plum, remains symptomless. Experimentally, also *Prunus persica* (L.) Batsch, peach.

Insusceptible species: *ROSACEAE—Prunus avium* L., cherry.

Geographical distribution: United States (New York); Canada (British Columbia, Ontario).

Induced disease: In prune, leaves small, narrow, rugose, distorted, glazed. Internodes short. Some branches escape and appear normal. Blossoms numerous, mature fruits few. Pistils aborted, petals narrow and distorted. In Damson and Bradshaw plums, no obvious manifestations of disease as a result of infection.

Transmission: By budding and other forms of grafting. Not demonstrated by inoculation of expressed juice. No insect vector is known.

Literature: Berkeley, Canada, Domin. Dept. Agr., Div. of Bot. and Plant Path., Science Service, Publ. 679, 1941; Hildebrand, Phytopath., *32*, 1942, 741–751; Thomas and Hildebrand, Phytopath., *26*, 1936, 1145–1148.

8. **Nanus sacchari** H. (*loc. cit.*, 129). From New Latin *Saccharum*, generic name of sugar cane, from Latin *saccharum*, sugar.

Common name: Sugar-cane sereh-disease virus.

Host: *GRAMINEAE—Saccharum officinarum* L., sugar cane.

Geographical distribution: Java, Borneo, Sumatra, Moluccas, India, Mauritius, Australia, Fiji, Formosa, Hawaii, Ceylon.

Induced disease: In sugar cane (Cheribon variety), plant dwarfed, shoots stunted, vascular bundles colored by the presence of a red gum; adventitious roots from many or all nodes.

Transmission: Not by inoculation of expressed juice. No insect vector is known.

Thermal inactivation: In cuttings of sugar cane, at 52° C in 30 minutes to 1 hour. Infected cane cuttings survive the heat treatment required for cure through inactivation of the causative virus.

Literature: Houtman, Arch. Suikerind. Nederland.-Indië, *33*, 1925, 631–642; Lyon, Bull. Exp. Sta. Hawaiian Sugar Planters' Assoc., Bot. Ser., *3*, 1921, 1–43; Wilbrink, Arch. Suikerind. Nederland.-Indië, *31*, 1923, 1–15.

Genus V. Rimocortius *Milbrath and Zeller.*

(Phytopath., *32*, 1942, 430.)

Viruses of the Rough-Bark Group, inducing diseases principally affecting bark, less often wood, leaves, or fruit. Generic name from Latin *rima*, cleft or fissure, and *cortex*, bark.

The type species is *Rimocortius kwanzani* Milbrath and Zeller.

(NOTE: The genus *Citrivir* (first named species, *Citrivir psorosis* Fawcett, Phytopath., *31*, 1941, 357) was proposed by its author as a *genus pro tempore* with the avowed purpose of accommodating viruses causing diseases in species of the plant-host genus *Citrus*. It appears to have been implied by the term *genus pro tempore* that evidences of natural relationship, when discovered, would permit even the first-named species of this genus to be assigned elsewhere. On the assumption that a permanent genus is nothing more than a *type species* and such other species as may be added to it by one or another author, it must be felt that a *genus pro tempore*, however convenient as an expedient, cannot become a permanent genus under any circumstances, because its first-named species would appear not to be a permanent part of the genus and so intended not to be a true type-species. Without a type species there would seem to be no permanent genus concept.

The system by which the term *Citrivir* was coined (explained by its author as use of the genitive of the host-genus name, *Citris*, plus *vir*, signifying virus) seems in itself acceptable, for it is commonly agreed that a generic name may be made in an arbitrary manner. It may be noted that use of the stem of the host-genus name (*Citr-*) with connecting vowel *i* and suffix *-vir*, possibly a more orthodox procedure, would have given the same result in the present instance. The original definition of the term *Citrivir* might be thought to be repugnant as disregarding concepts of natural interspecific relationships that are essential to the spirit of binomial nomenclature. Were the genus to be regarded as permanent rather than *pro tempore*, however, the scope of the genus would come to be wholly changed by usage, when, with passage of time related species would be added to what in this case would be a type species, without regard to the unorthodox intent of the original definition but solely in accordance with similarities between viruses. A generic concept need never be accepted as rigidly defined, whether initially, as has been attempted in this case, or upon further experience, because a genus may still grow by the addition of closely allied new species beyond any limit that may be set. On this account an original, or any subsequent, definition may be regarded as subject to unlimited change so long as the type species is logically retained. The form and definition of the term *Citrivir* would not, therefore, militate against its continued use. Its avowedly temporary status alone seems decisively to do so.

The originally monotypic genus *Rimocortius*, published in the following year, was defined only by the combined generic and specific description, and was not referred to a family by its authors. The type, because at first the only species, *Rimocortius kwanzani*, is the flowering-cherry rough-bark virus. This type species might well be associated with the species *Citrivir psorosis*, citrus-psorosis virus, discussed above, both affecting bark principally, though foliage also to some extent. Although the genus *Citrivir* was named in 1941 and *Rimocortius* not until 1942, the first was intended as a temporary assemblage only, as above indicated. It would seem appropriate, therefore, to include the virus that was known temporarily as *Citrivir psorosis* in the permanent genus *Rimocortius* Milbrath and Zeller and to assign this genus to the family *Marmoraceae*.)

Key to the species of the genus **Rimocortius.**

I. Affecting cherry.
   1. *Rimocortius kwanzani.*

II. Affecting *Citrus*.
   2. *Rimocortius psorosis.*

III. Affecting pear.
   3. *Rimocortius pyri.*

1. **Rimocortius kwanzani** Milbrath and Zeller. (Phytopath., *32*, 1942, 430.) From Kwanzan, name of a variety of flowering cherry.

Common name: Flowering-cherry rough-bark virus.

Hosts: *Prunus serrulata* Lindl. var. Kwanzan, flowering cherry; *P. avium* L., Mazzard cherry.

Geographical distribution: United States (Oregon).

Induced disease: In flowering cherry, tree dwarfed, deficient in lateral branches; bark deep brown, roughened, splitting longitudinally; internodes shortened, bunching leaves; leaves arched downward; midribs of leaves split and cracked on under surface. In Mazzard cherry, no manifestation of disease, but carrier condition; budded Mazzard stock may transmit disease to healthy Kwanzan cherry cions.

Transmission: By budding, generally even if the inserted bud fails to survive.

Literature: Milbrath and Zeller, Phytopath., *32*, 1942, 428–430; Thomas, *ibid.*, *32*, 1942, 435–436.

2. **Rimocortius psorosis** (Fawcett) *comb. nov.* (*Citrivir psorosis* Fawcett, Phytopath., *31*, 1941, 357.) Specific name meaning "of the disease known as psorosis."

Common name: Citrus-psorosis virus.

Hosts: *RUTACEAE—Citrus sinensis* Osbeck, orange; *C. limonia* Osbeck, lemon; *C. maxima* Merr., grapefruit.

Geographical distribution: World-wide where citrus trees are grown.

Induced disease: In citrus, small, elongated, light colored areas or flecks in the region of small veins on young, tender foliage; leaves sometimes warped; (chlorotic?) clearing of veins, and chlorotic line patterns, sometimes concentric. Outer layers of bark scale away; depressions and deformities appear in bark and wood. Lemons, as a rule, are more tolerant than oranges and are not subject to the bark changes.

Transmission: By grafting, including root grafting and patch bark grafting. Not by inoculation of expressed juice. No insect vector is known.

Literature: Bitancourt et al., Phytopath., *33*, 1943, 865–883; Fawcett, *ibid.*, *24*, 1934, 659–668; Science, *92*, 1940, 559–561; Phytopath., *31*, 1941, 356–357; Fawcett and Bitancourt, *ibid.*, *33*, 1943, 837–864; Rhoads, *ibid.*, *32*, 1942, 410–413; Webber and Fawcett, Hilgardia, *9*, 1935, 71–109.

Strains: Three strains differing from the type have been recognized. The type, var. *vulgare* Fawcett, Phytopath., *31*, 1941, 357, causes psorosis A, the common scaly-bark type of disease, with pustular eruptions of outer layers of bark in limited areas, with or without exudation of gum; later a drab-gray, cinnamon-drab to rufus discoloration of the wood, accompanied by decline of the affected tree. Others, that contrast with the type, are:

2a. *Rimocortius psorosis* var. *anulatum* Fawcett. (Phytopath., *31*, 1941, 357.) From Latin *anulatus*, with a ring. Causing psorosis B, known from California, resembling zonate chlorosis of Brazil in effects on leaves and fruits. Psorosis B is characterized by rapid scaling of outer bark in continuous areas, progressing rapidly along one side of trunk or branch; gum exudes in advance of scaling, necrosis follows; large circular discolored and corky spots, sometimes concentric, on fruits and mature leaves; on some fruits, circular or semi-circular furrows and bumps; rapid decline of the affected tree.

2b. *Rimocortius psorosis* var. *concavum* Fawcett and Bitancourt. (Phytopath., *33*, 1943, 850.) From Latin *concavus*, concave. Causing concave-gum psorosis, characterized by concavities of various sizes on trunks and larger limbs of affected trees, often by zonate patterns on young leaves during periods of rapid growth.

2c. *Rimocortius psorosis* var. *alveatum* Fawcett and Bitancourt. (Phytopath., *33*, 1943, 854.) From Latin *alveatus*, hollowed out like a trough. Causing blind-pocket psorosis, characterized by trough-like pockets in bark and wood or by eruptive lesions.

3. **Rimocortius pyri** (Holmes) *comb. nov.* (*Marmor pyri* Holmes, Handb. Phytopath. Viruses, 1939, 76.) From New Latin *Pyrus*, generic name of pear, from Latin *pirus*, pear tree.

Common name: Pear stony-pit virus.

Host: *ROSACEAE—Pyrus communis* L., pear.

Geographical distribution: United States (Oregon, Washington, California).

Induced disease: In pear, fruit deeply pitted and deformed; bark cracked and resembling oak bark; veinlet chlorosis of some leaves, failure of lateral buds to grow, reduction of foliage. Bartlett and Comice varieties of pear appear to be tolerant, producing sound fruit from infected trees.

Transmission: By budding. Not by inoculation of expressed juice. No insect vector is known.

Literature: Kienholz, Phytopath., *29*, 1939, 260–267; *30*, 1940, 787 (Abst.).

Genus VI. Adelonosus *Brierley and Smith.*

(Phytopath., *34*, 1944, 551.)

Viruses capable of multiplying in living plants but producing no recognizable symptoms in these except on interaction with distinct viruses with which they form complexes. Transmitted by aphids, by sap, or by both means. Generic name from Greek *adelos*, invisible, and *nosos*, disease. Only one species is recognized thus far; this is the type species, *Adelonosus lilii* Brierley and Smith.

1. **Adelonosus lilii** Brierley and Smith. (Phytopath., *34*, 1944, 551.) From Latin *lilium*, lily.

Common name: Lily-symptomless virus.

Host: *LILIACEAE—Lilium longiflorum* Thunb., Easter lily.

Insusceptible species: All other tested lilies and many related plants in the same and other families (for list, see Phytopath., *34*, 1944, 549).

Geographical distribution: United States, Japan; probably coextensive with commercial culture of Easter lily.

Induced disease: In Easter lily, no obvious manifestation of disease when this virus is present alone; when together with cucumber-mosaic virus, however, the lily-symptomless virus is a determining factor in the production of necrotic-fleck disease; the lily-symptomless virus is so widely distributed in supposedly healthy stocks of the Easter lily that cucumber-mosaic virus formerly was thought to be the sole determining factor in necrotic flecking, now recognized to be caused by the virus complex lily-symptomless virus (*Adelonosus lilii*) *plus* cucumber-mosaic virus (*Marmor cucumeris*); the complex acts independently of the presence or absence of lily latent-mosaic virus (*Marmor mite*), which is often present with the essential members of the complex in flecked Easter lilies.

Transmission: By inoculation of expressed juice, with some difficulty. By aphid, *Aphis gossypii* Glov., cotton aphid (*APHIDIDAE*); preinfective period after obtaining virus, 4 to 6 days.

FAMILY III. ANNULACEAE HOLMES.

(Handb. Phytopath. Viruses, 1939, 97.)

Viruses of the Ringspot Group, causing diseases usually characterized by necrotic or chlorotic spotting with concentric-ring lesions and eventual recovery from obvious disease with non-sterile immunity. Hosts, higher plants; vectors unknown. There is a single genus.

Genus I. **Annulus** *Holmes.*

(*Loc. cit.*, 97.)

Characters those of the family. Generic name from Latin *annulus*, a ring.

The type species is *Annulus tabaci* Holmes.

Key to the species of genus **Annulus.**

I. Found occurring naturally in the Western Hemisphere.
  A. In tobacco.
    1. *Annulus tabaci.*
    2. *Annulus zonatus.*
    3. *Annulus orae.*
    4. *Annulus apertus.*
  B. In potato.
    5. *Annulus dubius.*
  C. In delphinium.
    6. *Annulus delphinii.*
II. Old World species.
    7. *Annulus bergerac.*

1. **Annulus tabaci** Holmes. (Handb. Phytopath. Viruses, 1939, 98; *Marmor anularium* McKinney, Jour. Washington Acad. Sci., *34*, 1944, 327.) From New Latin *Tabacum*, early generic name for tobacco.

Common names: Tobacco-ringspot virus, green ringspot virus, yellow ringspot virus, ring spot No. 1 virus.

Hosts: *SOLANACEAE—Nicotiana tabacum* L., *Petunia violacea* Lindl., *Solanum tuberosum* L. *CUCURBITACEAE—Cucumis sativus* L. Experimentally this virus has been found capable of infecting many species of plants in a large number of families; these include all tested species of the *SOLANACEAE, SCROPHULARIACEAE, COMPOSITAE,* and *CUCURBITACEAE.* Many species of the *LEGUMINOSAE* are susceptible and one, *Vigna sinensis* (L.) Endl., is used as an indicator plant for quantitative measurement because it displays conspicuous reddish-brown necrotic lesions around points of initial infection.

Geographical distribution: United States.

Induced disease: In tobacco, necrotic ring-like primary lesions, followed by secondary necrotic rings on younger leaves. Subsequently, affected plants recover. After recovery from obvious disease, virus content of plants is only 10 to 20 per cent of that of recently infected plants. Some varieties may show mosaic-like patterns in young leaves at 16°C.

Transmission: By inoculation of expressed juices. Through about 20 per cent of seeds from diseased petunia plants. Not by dodder, *Cuscuta campestris* Yuncker (*CONVOLVULACEAE*).

Serological relationships: Induces the formation of specific precipitating antibodies when injected into bloodstream of rabbit.

Immunological relationships: Recovered tobacco plants are not susceptible to reinfection with this virus but are readily infected with *Annulus zonatus* or *A. orae.* This virus produces primary lesions on

leaves of plants immune to reinfection with *A. bergerac*.

Thermal inactivation: At 68° C in 10 minutes.

Filterability: Passes V, N, and perhaps W Berkefeld filters.

Other properties: Particle size estimated by filtration experiments as about 19 millimicrons. Sedimentation constant, $S_{20°} = 115 \times 10^{-13}$ cm. sec.$^{-1}$ dyne^{-1}. Infective in dilutions of 10^{-7} after purification. Inactivated in 1 hour below pH 3 or above pH 10.8. Recovered plants of tobacco contain 0.002 mg of virus per gram, recently infected plants about 6 times as much. Optimum conditions for retaining infectivity of stored virus include suspension in 0.01 M phosphate buffer at pH 7 and storage at 4° C.

Literature: Fenne, Phytopath., *21*, 1931, 891–899; Fromme et al., *ibid.*, *17*, 1927, 321–328; Henderson, *ibid.*, *21*, 1931, 225–229; Henderson and Wingard, Jour. Agr. Res., *43*, 1931, 191–207; Price, Contrib. Boyce Thompson Inst., *4*, 1932, 359–403; Phytopath., *26*, 1936, 503–529; Am. Jour. Bot., *27*, 1940, 530–541; Am. Naturalist, *74*, 1940, 117–128; Priode, Am. Jour. Bot., *15*, 1928, 88–93; Stanley, Jour. Biol. Chem., *129*, 1939, 405–428, 429–436; Stanley and Wyckoff, Science, *85*, 1937, 181–183; Valleau, Kentucky Agr. Exp. Sta., Bull. 327, 1932; Wingard, Jour. Agr. Res., *37*, 1928, 127–153; Woods, Contrib. Boyce Thompson Inst., *5*, 1933, 419–434.

Strains: A number of distinctive strains have been collected in nature and studied experimentally. The following have been given varietal names to distinguish them from the type, var. *virginiensis* H., *loc. cit.*, 98:

1a. *Annulus tabaci* var. *kentuckiensis* H. (*loc. cit.*, 99). Differing from the typical strain in producing less necrosis and less stunting in tobacco. (Price, Phytopath., *26*, 1936, 665–675; Valleau, Kentucky Agr. Exp. Sta., Bull. 327, 1932.)

1b. *Annulus tabaci* var. *auratus* H. (*loc. cit.*, 100). Secondary lesions in tobacco at first yellow spots or rings, becoming necrotic subsequently. Recovery less complete than with type, abnormal yellowing of old leaves tending to persist. (Chester, Phytopath., *25*, 1935, 686–701; Price, Phytopath., *26*, 1936, 665–675; Valleau, Kentucky Agr. Exp. Sta., Bull. 327, 1932; Phytopath., *29*, 1939, 549–551.)

2. **Annulus zonatus** H. (*loc. cit.*, 101). From Latin *zonatus*, zonate.

Common names: Tomato-ringspot virus, ring spot No. 2 virus.

Hosts: *SOLANACEAE—Nicotiana tabacum* L., tobacco. Experimentally this virus has been found to infect many species of plants in a large number of families.

Geographical distribution: United States.

Induced disease: In tobacco, zonate necrotic primary lesions and, temporarily, secondary lesions of the same type; recovery with specific, non-sterile immunity. In tomato, systemic infection, yellowish-green or necrotic ring-like lesions; stunting.

Transmission: By inoculation of expressed juice.

Immunological relationships: Recovered plants are immune to reinfection but are still susceptible to *Annulus tabaci*, *A. bergerac*, and several mosaic-type viruses that have been tested.

Thermal inactivation: At 55 to 60° C in 10 minutes.

Filterability: Passes Gradocol membrane 100 millimicrons in average pore diameter. Particle size estimated as 50 millimicrons or less.

Literature: Price, Phytopath., *26*, 1936 665–675; Am. Jour. Bot., *27*, 1940, 530–541.

3. **Annulus orae** H. (Holmes, *loc. cit.*, 103; *Tractus orae* Valleau, Phytopath., *30*, 1940, 826.) From Latin *ora*, edge, in reference to occurrence of induced disease near edge of tobacco fields.

Common name: Tobacco-streak virus.

Hosts: *SOLANACEAE—Nicotiana tabacum* L., tobacco. Experimentally, a

number of other solanaceous plants have been reported as susceptible, but not *Capsicum frutescens* L., pepper; *Lycopersicon esculentum* Mill., tomato; *Solanum melongena* L., eggplant; or *S. tuberosum* L., potato.

Geographical distribution: United States.

Induced disease: In tobacco, local and systemic necrosis in 3 days, with irregular spot, line, and ring-like lesions, followed by recovery from necrotic manifestations of disease. Recovered leaves may show a mild mottling and regularly contain virus; reinoculation does not induce formation of necrotic lesions in them.

Transmission: By inoculation of expressed juice. Not through seeds from diseased plants.

Immunological relationships: No cross-protection with respect to *A. tabaci*, and several viruses of the mosaic group.

Thermal inactivation: At 53° C in 10 minutes.

Literature: Johnson, Phytopath., *26*, 1936, 285–292; Trans. Wisconsin Acad. Sciences, Arts and Letters, *30*, 1937, 27–34.

4. **Annulus apertus** *spec. nov.* From Latin *apertus*, frank.

Common name: Broad-ringspot virus.

Hosts: *SOLANACEAE—Nicotiana tabacum* L., tobacco. Experimentally also to many species in this and other families.

Insusceptible species: *CHENOPODIACEAE—Beta vulgaris* L. *CUCURBITACEAE—Citrullus vulgaris* Schrad. *LEGUMINOSAE—Medicago sativa* L., *Melilotus alba* Desr.

Geographical distribution: United States (Wisconsin).

Induced disease: In tobacco, indistinct yellow-spot primary lesions, becoming chlorotic or necrotic rings with concentric markings; small chlorotic rings, sometimes concentric, or fine brown necrotic rings as secondary lesions; young leaves puckered at first, somewhat malformed.

Transmission: By inoculation of expressed juice.

Immunological relationships: Protects against reinfection with homologous virus but leaves host susceptible to infection by *Annulus tabaci*, *A. zonatus*, and some mosaic-type viruses.

Literature: Johnson and Fulton, Phytopath., *32*, 1942, 605–612.

5. **Annulus dubius** (Holmes) *comb.nov.* (*Marmor dubium* H., *loc. cit.*, 42.) From Latin *dubius*, uncertain, in reference to a common name, potato virus X, often used to designate this virus.

Common name: Potato-mottle virus (strains of this virus have been studied at various times under the names potato latent virus, potato virus X, potato-anecrosis virus, virulent latent virus, simple mosaic virus, healthy potato virus, Hyoscyamus IV virus, President streak virus, potato foliar-necrosis virus, potato acronecrotic streak virus, Up-to-Date streak virus, potato viruses B and D, Solanum viruses 1, 4, and 6.)

Hosts: *SOLANACEAE—Solanum tuberosum* L., potato; *Lycopersicon esculentum* Mill., tomato. Experimentally, also *SOLANACEAE—Capsicum frutescens* L., pepper; *Datura stramonium* L., Jimson weed; *Hyoscyamus niger* L., henbane; *Nicotiana tabacum* L., tobacco; *Physalis alkekengi* L.; *Solanum dulcamara* L., bittersweet; *S. nigrum* L., black nightshade. *AMARANTHACEAE—Amaranthus retroflexus* L. *COMPOSITAE—Chrysanthemum morifolium* Ram. *SCROPHULARIACEAE—Veronica* sp., common speedwell.

Geographical distribution: Widespread throughout the world; present in all known stocks of tubers of some potato varieties in the United States.

Induced disease: In potato, usually no chlorotic mottling, sometimes a little; intracellular inclusions of the vacuolated, granular type; some varieties that are virtually immune in the field owe their tendency to localize the virus in necrotic primary lesions or in top-necrosis of first systemically infected plants to a dom-

inant allele of a gene *nx*, which characterizes plants showing a mosaic of some degree of intensity on infection with this virus; the variety known as S41956 is immune to all tested strains of the virus and possesses two dominant genes both required for resistance. In tomato, systemic mild chlorotic mottling; if a strain of tobacco-mosaic virus is also present, a severe systemic necrosis, known as double-virus streak, is induced.

Transmission: By inoculation of expressed juice. Experimentally, by leaf contacts mainly under the influence of wind. No insect vector is known. Not transmitted through true seeds of the potato.

Serological relationships: Cross precipitin reactions between constituent strains of this virus. No cross reaction with potato aucuba-mosaic, potato mild-mosaic, potato-veinbanding, tobacco-mosaic, tobacco-etch, tobacco-ringspot or pea-mosaic virus. Antisera prepared by injecting rabbits intravenously with virus inactivated by nitrous acid, like those prepared with active virus, fix complement and flocculate with virus suspensions (though not with juice of healthy host plants); they are also effective in neutralizing the virus.

Immunological relationships: Tobacco and *Datura* plants infected by the type strain of this virus become immune to the more severe potato-ringspot strain. No protection against the severe strain is afforded by previous infection with tobacco-mosaic, tobacco-ringspot, tomato spotted-wilt, or cucumber-mosaic virus.

Thermal inactivation: At 70° C. in 10 minutes.

Filterability: Passes Pasteur-Chamberland L_1, L_3, and L_5 filters.

Other properties: Digested by 0.02 per cent solution of pepsin in 3 hours at pH 4, at 38° C. Digested also by trypsin. Inactivated by papaine and cyanide, but by neither separately. Isoelectric point near pH 4. Dilute solutions show anisotropy of flow. Concentrated solutions are spontaneously birefringent. Properties of the type strain have been less studied than those of the potato-ringspot strain of this virus.

Literature: Bawden, Proc. Roy. Soc. London, Ser. B, *116*, 1934, 375–395; Bawden and Pirie, Brit. Jour. Exp. Path., *17*, 1936, 64–74; Bawden et al., *ibid.*, *17*, 1936, 204–207; Blodgett, Phytopath., *17*, 1927, 775–782; Böhme, Phytopath. Ztschr., *6*, 1933, 517–524; Cadman, Jour. Genetics, *44*, 1942, 33–52; Chester, Phytopath., *27*, 1937, 903–912; Clinch, Sci. Proc. Roy. Dublin Soc., *23*, 1942, 18–34; Johnson, Wisconsin Agr. Exp. Sta., Res. Bull. 63, 1925; Koch, Phytopath., *23*, 1933, 319–342; Köhler, Phytopath. Ztschr., *5*, 1933, 567–591; *7*, 1934, 1–30; Loughnane and Murphy, Nature, *141*, 1938, 120; van der Meer, Cent. f. Bakt., II Abt., *87*, 1932, 240–262; Salaman, Nature, *131*, 1933, 468; Schultz et al., Phytopath., *27*, 1937, 190–197; *30*, 1940, 944–951; Spooner and Bawden, Brit. Jour. Exp. Path., *16*, 1935, 218–230; Stevenson et al., Phytopath., *29*, 1939, 362–365.

Strains: Several variants of potato-mottle virus, differing from the type, var. *vulgaris* H. (*loc. cit.*, 42), have been recognized as distinctive varieties under the following names:

5a. *Annulus dubius* var. *annulus* H. (*loc. cit.*, 44). From Latin *annulus*, ring.

Common name: Ringspot strain of potato-mottle virus. Necrotic primary and secondary ring-like lesions in experimentally infected tobacco plants. Indistinguishable from type strain by ordinary precipitin test, but distinguishable when appropriately absorbed sera are used. This strain has been more frequently studied than the type. Juice of infected tobacco plants contains about 0.02 to 0.10 mg of virus per ml. Sedimentation constants, $S_{20^\circ} = 113 \times 10^{-13}$ and 131×10^{-13} cm. sec.$^{-1}$ dyne^{-1}. Dissymmetry constant 2.78. Molecular weight 26×10^6. Particle size estimated to be 433 by 9.8 millimicrons, 43.9 times as long as wide. Isoelectric point near pH 4. Stable between pH 4 and pH 9.5. Concentrated solutions are spontaneously birefringent. Dilute solutions show

anisotropy of flow. Destroyed by drying. Inactivated by papaine and cyanide, but by neither separately. Digested by 0.02 per cent solution of pepsin in 3 hours at pH 4, at 38° C. Digested also by trypsin. About 6 per cent of the purified virus is reported to be a pentose nucleic acid, but the carbohydrate to phosphorus ratio is about twice that for yeast nucleic acid. Guanine and pentose present. Analysis of sedimented virus, carbon 47.7 to 49.5 per cent, hydrogen 6.8 to 7.7 per cent, nitrogen 14.6 to 17.0 per cent, phosphorus 0.4 to 0.7 per cent, sulfur 1.1 per cent, carbohydrate 2.5 to 4.3 per cent, ash 2.0 to 2.5 per cent. Reduction of carbohydrate content of sample to 2.5 per cent does not reduce activity of virus; further reduction inactivates. (Ainsworth, Ann. Appl. Biol., *21*, 1934, 581–587; Bawden, Brit. Jour. Exp. Path., *16*, 1935, 435–443; Bawden and Pirie, *ibid.*, *19*, 1938, 66–82; Birkeland, Bot. Gaz., *95*, 1934, 419–436; Chester, Phytopath., *26*, 1936, 778–785; Johnson, Wisconsin Agr. Exp. Sta., Res. Bull. *76*, 1927; Loring, Jour. Biol. Chem., *126*, 1938, 455–478; Loring and Wyckoff, *ibid.*, *121*, 1937, 225–230.)

5b. *Annulus dubius* var. *flavus* H. (*loc. cit.*, 46). From Latin *flavus*, yellow. Common name: Yellow-mottle strain of potato-mottle virus. Differing from the type by imparting a yellow cast to foliage of infected potatoes. (Putnam, Canad. Jour. Res., Sec. C, *15*, 1937, 87–107.)

5c. *Annulus dubius* var. *obscurus* H. (*loc. cit.*, 46). From Latin *obscurus*, obscure. Common name: Masked-mottle strain of potato-mottle virus. Differing from the type by systemically infecting potato, tobacco, and Jimson weed without symptoms under ordinary experimental conditions; in pepper, however, systemic necrosis is induced, as by all known strains. (Chester, Phytopath., *26*, 1936, 778–785.)

6. **Annulus delphinii** *spec. nov.* From New Latin *Delphinium*, generic name of host.

Common names: Delphinium-ringspot virus, perennial-delphinium ringspot virus.

Hosts: *RANUNCULACEAE—Delphinium* sp., perennial delphiniums. Experimentally, also to *CHENOPODIACEAE—Beta vulgaris* L. *CUCURBITACEAE—Cucumis sativus* L., cucumber. *MALVACEAE — Gossypium hirsutum* L. *RANUNCULACEAE—Ranunculus asiaticus* L. (symptomless carrier). *SOLANACEAE—Datura stramonium* L., *Nicotiana alata* Link and Otto, *N. glutinosa* L., *N. rustica* L., *N. tabacum* L., *Petunia hybrida* Vilm.

Geographical distribution: United States (California).

Induced disease: In perennial delphiniums, faint chlorotic rings with green or yellow centers on young leaves; irregular chlorotic spots, yellow bands, or irregular chlorotic rings on mature leaves.

Transmission: By inoculation of expressed juice in the presence of finely powdered carborundum.

Thermal inactivation: At 65° C in 10 minutes.

Literature: Severin and Dickson, Hilgardia, *14*, 1942, 465–490.

7. **Annulus bergerac** H. (*loc. cit.*, 102). From Bergerac, a town in southwest France.

Common name: Bergerac-ringspot virus.

Hosts: *SOLANACEAE—Nicotiana tabacum* L., tobacco. Experimentally, this virus has been transferred to several other solanaceous plants and to *Phaseolus vulgaris* L., bean, in the family *LEGUMINOSAE*.

Geographical distribution: France.

Induced disease: In tobacco, thin necrotic-ring primary lesions, followed by

systemic mottling with some chlorotic rings on the dark green islands. Later, complete recovery occurs, with non-sterile immunity.

Transmission: By inoculation of expressed juice.

Immunological relationships: Recovered plants are susceptible to infection by *Annulus tabaci* and *A. zonatus*.

Thermal inactivation: At 80° C in 10 minutes.

Literature: Smith, A textbook of plant virus diseases, P. Blakiston's Son and Co., Inc., Philadelphia, 1937, 285–289.

FAMILY IV. RUGACEAE HOLMES.

(Handb. Phytopath. Viruses, 1939, 114)

Viruses of the Leaf-Curl Group, causing diseases characterized by suddenly arrested development of invaded tissues, resulting in leaf curl, enations, and other deformities. Vectors, typically white-flies (*ALEYRODIDAE*). There is a single genus.

Genus I. Ruga *Holmes.*

(*Loc. cit.*, 114.)

Characters those of the family. Generic name from Latin *ruga*, a wrinkle. The type species is *Ruga tabaci* Holmes.

Key to the species of genus **Ruga.**

I. Infecting tobacco.
  1. *Ruga tabaci.*

II. Infecting cotton.
  2. *Ruga gossypii.*

III. Infecting cassava (*Manihot*).
  3. *Ruga bemisiae.*

IV. Infecting sugar-beet.
  4. *Ruga verrucosans.*

1. **Ruga tabaci** Holmes. (Handb. Phytopath. Viruses, 1939, 115.) From New Latin *Tabacum*, former generic name of tobacco.

Common names: Tobacco leaf-curl virus, kroepoek virus, curl-disease virus, crinkle-disease virus.

Hosts: *SOLANACEAE—Nicotiana tabacum* L., tobacco. *COMPOSITAE—Vernonia iodocalyx, V. cineria, Ageratum conyzoides* L., *Synedrella nodiflora* Gaertn. Experimentally, also other solanaceous plants.

Insusceptible species: *MALVACEAE—Gossypium hirsutum* L., cotton.

Geographical distribution: Tanganyika, Southern Rhodesia, Southern Nigeria, Nyasaland, India, Sumatra, Formosa.

Induced disease: In tobacco, leaves curled and crinkled, with occasional leafy outgrowths or enations. Veins greened and thickened. No chlorosis nor necrosis. Plant stunted.

Transmission: By white-fly, *Bemisia gossypiperda* Misra and Lamba (*ALEYRODIDAE*). By grafting. Not by inoculation of expressed juice.

Literature: Kerling, Phytopath., *23*, 1933, 175–190; Mathur, Indian Jour. Agr. Sci., *3*, 1933, 89–96; Matsumoto and Tateoko, Trans. Nat. Hist. Soc. Formosa, *30*, 1940, 31–33; Pal and Tandon, Indian Jour. Agr. Sci., *7*, 1937, 363–393; Pruthi and Samuel, *ibid.*, *7*, 1937, 659–670; Storey, Nature, *128*, 1931, 187–188; East African Agr. Jour., *1*, 1935, 148–153; Thung, Meded. Proefsta. Vorstenl. Tabak Java, *72*, 1932; *78*, 1934.

2. **Ruga gossypii** H. (*loc. cit.*, 116). From Latin *gossypium*, cotton.

Common names: Cotton leaf-curl virus, cotton leaf-crinkle virus.

Hosts: *MALVACEAE—Gossypium hirsutum* L., cotton; *G. peruvianum* Cav.; *G. vitifolium* Lam.; *Hibiscus cannabinus* L.; *H. esculentus* L.; *H. sabdariffa* L.; *Althaea rosea* Cav., hollyhock; Sakel (hybrid) cotton.

Geographical distribution: The Sudan and Nigeria, in Africa.

Induced disease: In cotton, clearing of veins, blistering and pale spotting of leaves; leaves puckered at edge and unsymmetrical. Internodes shortened, producing bunchy growth.

Transmission: By white-fly, *Bemisia gossypiperda* Misra and Lamba (*ALEY-

RODIDAE). Not through egg of insect vector. Not by inoculation of expressed juice. Not through soil. Not through seeds from diseased plants.

Literature: Bailey, Empire Cotton Growing Rev., *11*, 1934, 280; Kirkpatrick, Bull. Entom. Res., *21*, 1930, 127–137; *22*, 1931, 323–363.

3. **Ruga bemisiae** H. (Holmes, *loc. cit.*, 117; *Ochrosticta bemisiae* McKinney, Jour. Washington Acad. Sci., *34*, 1944, 149.) From New Latin *Bemisia*, generic name of insect vector.

Common names: Cassava-mosaic virus, cassava Kräuselkrankheit virus.

Hosts: *EUPHORBIACEAE—Manihot utilissima* Pohl, cassava; *M. palmata* Muell.; *M. dulcis*.

Geographical distribution: Gold Coast, Belgian Congo, French Cameroons, Rhodesia, Liberia, Madagascar, probably throughout Africa and adjacent islands; Java.

Induced disease: In *Manihot utilissima*, leaves unsymmetrical, curled, distorted, mottled; internodes shortened, plants stunted. Axillary buds produce an extra number of side branches.

Transmission: By white-flies (*ALEYRODIDAE*), *Bemisia nigeriensis* Corb., in Southern Nigeria, and *B. gossypiperda* Misra and Lamba, in Belgian Congo and Tanganyika. White-flies infect only young leaves. Not by needle-puncture, rubbing, or hypodermic-needle injection of juice expressed from diseased plants.

Literature: Dade, Yearbk. Dept. Agr. Gold Coast, 1930, 245; Dufrénoy and Hedin, Rev. Bot. Appl., *9*, 1929, 361–365; Golding, Trop. Agric., Trinidad, *13*, 1936, 182–186; Kufferath and Ghesquière, Compt. rend. Soc. Biol. Belge, *109*, 1932, 1146; Lefevre, Bull. Agr. Congo Belge, *26*, 1935, 442; McKinney, Jour. Agr. Res., *39*, 1929, 557–578; Muller, Bull. Inst. Plantenziekt., *24*, 1931, 1–17; Pascalet, Agron. Colon., *21*, 1932, 117; Staner, Bull. Agr. Congo Belge, *22*, 1931, 75; Storey, East Afr. Jour., *2*, 1936, 34–39; Storey and Nichols, Ann. Appl. Biol., *25*, 1938, 790–806; Zimmermann, Pflanzer, *2*, 1906, 145.

4. **Ruga verrucosans** Carsner and Bennett. (*Chlorogenus eutetticola* (in error for *eutettigicola*, from New Latin *Eutettix*, genus name of a vector, and Latin *-cola*, dweller in or inhabitant of) Holmes, 1939, *loc. cit.*, 11; Carsner and Bennett, Science *98*, 1943, 386.) From Latin, meaning: causing rough swellings.

Common name: Sugar-beet curly-top virus.

Hosts: Very wide range in many families of dicotyledonous plants. Among the horticulturally important host plants are the sugar beet (*Beta vulgaris* L., *CHENOPODIACEAE*); bean (*Phaseolus vulgaris* L., *LEGUMINOSAE*); squash (*Cucurbita* species, *CUCURBITACEAE*); and tomato (*Lycopersicon esculentum* Mill., *SOLANACEAE*).

Geographical distribution: Western North America; in Argentina a strain of virus thought to belong here has been reported but has not yet been fully described.

Induced disease: In beet, clearing of veins, leaf curling, sharp protuberances from veins on lower surface of leaves, increase in number of rootlets, phloem degeneration followed by formation of supernumerary sieve tubes, retardation of growth. In tomato, (western yellow blight or tomato yellows), phloem degeneration followed by formation of supernumerary sieve tubes, retardation of growth, dropping of flowers and buds, rolling, yellowing and thickening of leaves, root decay, usually followed by death, sometimes by recovery. Occasionally there is relapse after recovery. In cucurbitaceous plants, stunting, bending upward of tip of runner, yellowing of old leaves, abnormally deep green in tip leaves and stem; Marblehead squash is tolerant, showing only mild witches' broom formation and phyllody. In bean, infected when young, thickening and downward curling of first trifoliate leaf, which becomes brittle and will break easily from the stem; leaves become chlorotic, plant stops growing and usually dies soon; older plants are also susceptible to infection; they may survive until

the end of the season, showing puckering and downward curling of leaves at the top of the plant, reduction in size of new leaves, and shortened internodes, or they may gradually become chlorotic and die.

Transmission: By leafhopper, *Eutettix tenellus* (Baker) (*CICADELLIDAE*) with 4 to 12 hour preinfective period. Through dodder, *Cuscuta campestris* Yuncker (*CONVOLVULACEAE*). Not, with any regularity at least, by mechanical inoculation of expressed juice. Not through seeds of diseased plants to seedlings germinating from them. The leafhopper, *Agalliana ensigera* Oman (*CICADELLIDAE*), is said to transmit a South American strain of sugar-beet curly-top virus, but evidence for identity of the virus has not yet been reported in detail.

Thermal inactivation: At 75° to 80° C in 10 minutes.

Filterability: Passes Berkefeld V, N, and W, Mandler medium and fine, and Chamberland L_1, L_3, L_5, L_7, L_9, L_{11} and L_{13} filters.

Other properties: Withstands alcohol and acetone treatments. A pH of 2.9 or lower inactivates, but an alkaline reaction as high as pH 9.1 does not inactivate, in 2 hours. Virus active after at least 8 years in tissues of thoroughly dried young sugar-beet plants, 6 months in dried leafhoppers, and 10 months in dried phloem exudate.

Strains: In general it has proved possible to modify strains by host passage, some hosts like *Chenopodium murale* L. appearing to select less virulent strains, others like *Stellaria media* (L.) Cyr. reversing this selection and restoring virulence.

Literature: Bennett, Jour. Agr. Res., *48*, 1934, 665–701; *50*, 1935, 211–241; *56*, 1938, 31–52; Phytopath., *32*, 1942, 826–827; Carsner, Phytopath., *15*, 1925, 745–757; U. S. Dept. Agr., Tech. Bull. 360, 1933; Jour. Agr. Res., *33*, 1926, 345–348; Dana, Phytopath., *28*, 1938, 649–656; Fawcett, Revista Industrial y Agrícola de Tucumán, *16*, 1925, 39–46; Fife, Phytopath., *30*, 1940, 433–437; Giddings, Phytopath., *27*, 1937, 773–779; Jour. Res., *55*, 1937, 453–460; Lesley and Wallace, Phytopath., *28*, 1938, 548–553; Murphy, *ibid.*, *30*, 1940, 779–784; Severin, Hilgardia, *3*, 1929, 595–636; Severin and Freitag, *ibid.*, *8*, 1933, 1–48; Severin and Henderson, Hilgardia, *3*, 1928, 339–393; Severin and Swezy, Phytopath., *18*, 1928, 681–690; Shaw, U. S. Dept. Agr., Bull. 181, 1910.

FAMILY V. SAVOIACEAE HOLMES.

(Handb. Phytopath. Viruses, 1939, 131.)

Viruses of the Savoy-Disease Group, causing diseases characterized mainly by crinkling of foliage. Vectors, true bugs (*PIESMIDAE* and *MIRIDAE*). There is a single genus.

Genus I. **Savoia** *Holmes.*

(*Loc. cit.*, 131.)

Characters those of the family. Generic name from French *chou de Savoie*, cabbage of Savoy, a cabbage with wrinkled and curled leaves.

The type species is *Savoia betae* Holmes.

Key to the species of genus **Savoia.**

I. Infecting beet.
- 1. *Savoia betae.*
- 2. *Savoia piesmae.*

II. Infecting rape and rutabaga.
- 3. *Savoia napi.*

1. **Savoia betae** Holmes. (Handb. Phytopath. Viruses, 1939, 132.) From Latin *beta*, beet.

Common names: Beet-Kräuselkrankheit virus, sugar-beet leaf-curl virus, sugar-beet leaf-crinkle virus, Kopfsalat virus.

Host: *CHENOPODIACEAE—Beta vulgaris* L., beet.

Geographical distribution: Germany, Poland.

Induced disease: In beet, veins of leaves swollen, retarded in growth, causing crinkling. New leaves remain small and incurved, forming a compact head. Old leaves die; plant succumbs before harvest time. Prepatent period in plant, 3 to 9 weeks.

Transmission: By tingid bug, *Piesma quadrata* Fieb. (*PIESMIDAE*). Not by inoculation of expressed juice.

Literature: Wille, Arb. Biol. Reichsanst. Land- u. Forstw., *16*, 1928, 115–167.

2. **Savoia piesmae** H. (*loc. cit.*, 132). From New Latin *Piesma*, generic name of insect vector.

Common name: Beet-savoy virus.

Host: *CHENOPODIACEAE—Beta vulgaris* L., beet.

Geographical distribution: United States (Michigan, Ohio, Minnesota, Nebraska, South Dakota, Colorado, Wyoming) and Canada.

Induced disease: In beet, leaves dwarfed, curled down, small veins thickened. Phloem necrosis in roots. Prodromal period in plant, 3 to 4 weeks.

Transmission: By tingid bug, *Piesma cinerea* (*PIESMIDAE*). Not by inoculation of expressed juice.

Literature: Coons et al., Phytopath., *27*, 1937, 125 (Abst.); Hildebrand and Koch, *ibid.*, *32*, 1942, 328–331.

3. **Savoia napi** H. (*loc. cit.*, 133). From New Latin *Napus*, former generic name of rape, *Brassica napus* L.

Common name: Rape-savoy virus.

Hosts: *CRUCIFERAE—Brassica napus* L., rape; *B. napobrassica* Mill., rutabaga.

Geographical distribution: Germany.

Induced disease: In rape, twisting and crinkling of young leaves; premature death of old leaves and of plants; in surviving plants, inhibition of growth in spring. In rutabaga, mottling and crinkling of leaves, with formation of fissures at leaf edges. Plants rarely killed.

Transmission: By inoculation of expressed juice. By the tarnished plant bug, *Lygus pratensis* Linn. (*MIRIDAE*). The insect vector retains this virus during intervals between crops.

Literature: Kaufmann, Arb. Biol. Reichsanst. Land- u. Forstw., *21*, 1936, 605–623; Mitteil. Landwirtsch., *37*, 1936; Pape, Deutsch. Landwirtsch. Presse, *26*, 1935.

FAMILY VI. LETHACEAE HOLMES.

(Handb. Phytopath. Viruses, 1939, 135.)

Virus strains of the Spotted-Wilt Group, causing diseases characterized by bronzing of foliage, streaking of stems, blighting of tips, necrotic spotting of foliage. Hosts, higher plants; vectors, thrips (*THRIPIDAE*). There is a single genus.

Genus I. **Lethum** *Holmes.*

(*Loc. cit.*, 135.)

Characters those of the family. Generic name from Latin *lethum*, death. At present there is but one known species, though this is reported to be nearly world-wide in distribution. In some areas it may have been confused with entities needing separate recognition.

The type species is *Lethum australiense* Holmes.

1. **Lethum australiense** Holmes (*loc. cit.*, 136). From Australia, where virus was first described.

Common names: Tomato spotted-wilt virus, kromnek or Kat River disease virus. Also, pineapple yellow-spot or side-rot virus (according to Sakimura, Phytopath., *30*, 1940, 281–299).

Hosts: Very numerous species in many families of higher plants. Among those most often noted are: *SOLANACEAE*—*Lycopersicon esculentum* Mill., tomato; *Nicotiana tabacum* L., tobacco; *Solanum tuberosum* L., potato. *COMPOSITAE*—*Lactuca sativa* L., lettuce. *LEGUMINOSAE*—*Pisum sativum* L., pea. *BROMELIACEAE*—*Ananas comosus* Merr., pineapple.

Geographical distribution: Australia, British Isles, United States, South Africa Hawaii, New Zealand, Europe, China, South America.

Induced disease: In tomato, bronze ring-like secondary lesions, plant stunted, some necrosis; later yellowish mosaic with some leaf distortion. Fruit frequently marked with concentric rings of pale red, yellow, or white. In tobacco, primary necrotic lesions followed by systemic necrosis, with stem streak, crookneck, often stunting with subsequent wilting and death, sometimes temporary recovery followed by recurrence of systemic necrosis. In lettuce, plant yellowed, retarded in growth; brown blemishes in central leaves, affected spots dying, becoming like parchment but with brown margins. Axillary shoots may show chlorotic mottling. In pea, purplish necrotic streaks on stem; at first, leaves mottled; later, necrotic spots damage foliage; pods show circular necrotic spots or wavy lines, or, if severely affected, may collapse; seeds may show necrotic lesions. In potato, zonate necrotic spots on upper leaves, necrotic streaks on stems; stems collapse at top; plant is stunted, yield of tubers small. In pineapple, at first an initial spot or primary lesion ⅛ to ½ inch in diameter, raised, yellowish, on upper surface of young leaf; later chlorotic spotting of young leaves, crook-neck because of necrotic foci in stems and fruits (side rot); plant may die.

Transmission: By inoculation of expressed juice; the addition of fine carborundum powder to inoculum facilitates transmission by rubbing methods. By thrips, *Frankliniella lycopersici* Andrewartha (formerly identified as *F. insularis* Franklin), *F. occidentalis* Perg., *F. moultoni* Hood. and *F. schultzei* (Trybom) (*THRIPIDAE*). Also by *Thrips tabaci* Lind. (*THRIPIDAE*). In *F. lycopersici*, thrips must pick up virus while still a nymph; virus persists through pupation and emergence as adult; preinfective period in vector, 5 to 9 days. Virus is not transmitted through eggs of

infective thrips. Probably not through seeds of infected plants. Not through soil.

Immunological relationships: Infects tobacco plants previously infected with tobacco-mosaic, potato-mottle, tobacco-ringspot, and tomato-ringspot viruses.

Thermal inactivation: At 42° C in 10 minutes.

Filterability: Passes Gradocol membrane of 0.45 micron pore diameter.

Other properties: Virus readily inactivated by desiccation or by action of oxidizing agents; activity prolonged by presence of sodium sulfite, cystein, or by low temperatures. Unstable at pH values below 6 and above 9.

Literature: Ainsworth et al., Ann. Appl. Biol., *21*, 1934, 566–580; Andrewartha, Trans. Roy. Soc. of So. Australia, *61*, 1937, 163–165; Bald and Samuel, *ibid.*, *21*, 1934, 179–190; Berkeley Scientific Agr., *15*, 1935, 387–392; Best Austral. Chem. Inst. Agr., *54*, 1937, 278–283; Whipple, Phytopath., *26*, 1936, 918–920.

Strains: A strain differing somewhat from the type, var. *typicum* H. (*loc. cit.*, 136), has been described as damaging tomatoes in the northwestern United States. It has been given a distinctive varietal name:

1a. *Lethum australiense* var. *lethale* H. (*loc. cit.*, 138). From Latin *lethalis*, deadly. Common names: Tip-blight strain of tomato spotted-wilt virus, Oregon tip-blight virus, tomato die-back streak virus, tomato tip-blight virus. Differs from the type in causing necrotic leaf spotting, stem streaking, and tip blighting in most hosts, without mottling or bronzing of foliage; yet in *Tropaeolum majus* L., there is little necrosis. In tomato, systemic necrosis, terminal shoots blighted and blackened; dead tips stand upright above living foliage. Fruits rough and pitted, with internal pockets of necrotic tissue or with subepidermal necrosis, appearing externally as concentric brown bands. (McWhorter and Milbrath, Oregon Agr. Exp. Sta., Circ. *128*, 1938; Milbrath, Phytopath., *29*, 1939, 156–168.)

SUBORDER III. **Zoophagi[illegible]e** *subordo novus.*

From Greek *phagein*, to eat, and *zoon*, an animal. Viruses infecting animals but having no plant hosts, so far as known.

Key to the families of suborder **Zoophaginae.**

1. Inducing diseases in insects as exclusive hosts.
   Family I. *Borrelinaceae*, p. 1225.
2. Inducing diseases of the pox group.
   Family II. *Borreliotaceae*, p. 1229.
3. Inducing diseases of the encephalitis group.
   Family III. *Erronaceae*, p. 1248.
4. Inducing diseases of the yellow-fever group.
   Family IV. *Charonaceae*, p. 1265.
5. Inducing diseases of the infectious anemia group.
   Family V *Trifuraceae*, p. 1282.
6. Inducing diseases of the mumps group.
   Family VI. *Rabulaceae*, p. 1284.

FAMILY I. BORRELINACEAE *FAM. NOV.*

Viruses causing polyhedral, wilt, and other diseases in arthropods. The genus *Borrelina* Paillot was originally spelled *Borrellina* by error; from Borrel, name of French scientist.

Key to the genera of family **Borrelinaceae.**

I. Known only as attacking lepidopterous insects.
   Genus I. *Borrelina*, p. 1225.
II. Known only as attacking the honey bee, a hymenopterous insect.
   Genus II. *Morator*, p. 1227.

Genus I. **Borrelina** *Paillot.*

(Compt. rend. Acad. Sci., Paris, *182*, 1926, 182.)

Viruses inducing polyhedral, wilt, and other diseases; hosts, Lepidoptera, so far as known.

The type species is *Borrelina bombycis* Paillot.

Key to the species of genus **Borrelina.**

I. Attacking silkworm.
   1. *Borrelina bombycis.*
II. Attacking nun moth.
   2. *Borrelina efficiens.*
III. Attacking gypsy moth.
   3. *Borrelina reprimens.*
IV. Attacking cabbage worm.
   4. *Borrelina brassicae.*
   5. *Borrelina pieris.*

1. **Borrelina bombycis** Paillot. (Compt. rend. Acad. Sci., Paris, *182*, 1926, 182.) From Latin *bombyx*, silkworm. (Note: Coccus-like bodies surrounded by non-staining substances, associated with the induced disease, received the provisional name *Chlamydozoon bombycis* from Prowazek, Arch. f. Protistenkunde, *10*, 1907, 363.)

Common names: Silkworm-jaundice virus, silkworm-grasserie virus, silkworm wilt virus, Gelbsucht virus, Fettsucht virus.

Host: *BOMBYCIDAE—Bombyx mori* (L.), silkworm.

Geographical distribution: Japan, Italy, France.

Induced disease: In silkworm, after prodromal period of 5 days or more, yellow spots on skin, polyhedral bodies in blood, inactivity, loss of appetite, irritability, weakening of body facilitating rupture from mechanical stress, eventual death.

Transmission: By feeding. Experimentally, also by injection.

Serological relationships: Specific agglutination, precipitation, and complement fixation.

Thermal inactivation: At 60° C in 15 to 20 minutes in blood.

Filterability: Passes Berkefeld N and V, Chamberland L_1, L_2, and L_3 filters.

Other properties: May survive at least 2 years in dry state. Stable between pH 5 and about pH 9. Sedimentation constant 17 S.

Literature: Aoki and Chigasaki, Cent. f. Bakt., I Abt., Orig., *86*, 1921, 481–485; Glaser and Lacaillade, Am. Jour. Hyg., *20*, 1934, 454–464; Glaser and Stanley, Jour. Exp. Med., *77*, 1943, 451–466; v. Prowazek, Cent. f. Bakt., I Abt., Orig., *67*, 1912, 268–284; Suzuki, Bull. Imperial Kyoto Sericultural College, *1*, 1929, 45–75; Trager, Jour. Exp. Med., *61*, 1935, 501–513.

2. **Borrelina efficiens** *spec. nov.* From Latin *efficiens*, effective, in reference to effectiveness of this virus in controlling nun-moth infestations.

Common names: Nun-moth disease virus, nun-moth wilt virus, Wipfelkrankheit virus.

Host: *LYMANTRIIDAE—Lymantria monacha* (L.), nun moth.

Geographical distribution: Europe.

Induced disease: In eggs, larvae, pupae and occasionally adults of nun moth, polyhedral bodies in affected tissues. Blood of sick larvae turbid; later, blood cells few; contents of body finally become a gray-brown, semifluid mass.

Transmission: By feeding.

Thermal inactivation: At 55 to 60° C in 5 to 10 minutes.

Filterability: Fails to pass Berkefeld and Chamberland filters.

Other properties: May remain viable at least 2 years in dry state.

Literature: Escherich and Miyajima, Naturwissens. Ztschr. f. Forst- u. Landwirtschaft, *9*, 1911, 381–402; Wachtl and Kornauth, Mitth. a. d. forstl. Versuchswesen Österreichs, *16*, 1893, 1–38; Wahl, Centralbl. Gesam. Forstw., *35*, 1909, 164–172; 212–215; *36*, 1910, 377–397; *37*, 1911, 247–268; *38*, 1912, 355–378.

3. **Borrelina reprimens** *spec. nov.* From Latin *reprimere*, to restrain.

Common name: Gypsy-moth wilt virus.

Host: *LYMANTRIIDAE—Porthetria dispar* (L.), gypsy moth.

Geographical distribution: United States.

Induced disease: In gypsy moth caterpillar, flaccidity, disintegration of tissues, eventual collapse as a watery sack. Death occurs in 13 to 29 (average 21) days after infection; caterpillar may remain attached to its support by prolegs; skin ruptures easily. Polyhedral bodies originate in nuclei of the tracheal matrix, hypodermal, fat, and blood cells.

Transmission: By feeding on contam-

inated foliage. Not through undamaged skin.

Filterability: Passes Berkefeld N, not Pasteur-Chamberland F, filter.

Literature: Chapman and Glaser, Jour. Econ. Entomol., *8*, 1915, 140–150; *9*, 1916, 149–167; Glaser, Jour. Agr. Res., *4*, 1915, 101–128; Science, *48*, 1918, 301–302; Glaser and Chapman, Jour. Econ. Entomol., *6*, 1913, 479–488.

4. **Borrelina brassicae** Paillot. (Compt. rend. Acad. Sci., Paris, *182*, 1926, 182.) From name of host, *Pieris brassicae.*

Common name: Cabbage-worm grasserie virus.

Host: *PIERIDAE—Pieris brassicae* (L.), cabbage worm.

Induced disease: In cabbage worm, no nuclear or cytoplasmic inclusions; nuclei of fat and hypodermal cells hypertrophied and soon disorganized.

Transmission: By feeding.

Other properties: Described as submicroscopic in size, intracytoplasmic.

Literature: Paillot, *loc. cit.*; Ann. Inst. Pasteur, *40*, 1926, 314–452; L'infection chez les insectes. Immunité et symbiose, 535 pages, Trévoux, Patissier, 1933.

5. **Borrelina pieris** Paillot. (Compt. rend. Acad. Sci., Paris, *182*, 1926, 182.) From New Latin *Pieris*, generic name of host.

Common name: Virus of nuclear disease of pierids.

Host: *PIERIDAE—Pieris brassicae* (L.), cabbage worm.

Induced disease: In cabbage worm, body yellowish below, tears easily just before death; chromatin of nuclei in fat and blood cells condensed in irregular masses; cytoplasmic inclusions staining faintly red in Giemsa preparations.

Transmission: By feeding.

Other properties: Described as intracytoplasmic, less than 0.1 micron in diameter.

Literature: Paillot, *loc. cit.*; Ann. Inst. Pasteur, *40*, 1926, 314–452; L'infection chez les insectes. Immunité et symbiose, 535 pages, Trévoux, Patissier, 1933.

Appendix: *Borrelina flacheriae* quoted from Paillot, L'infection chez les insects. 535 pp., Trevoux, Patissier, 1935, see p. 96. Cause of gattine in the silkworm, *Bombyx mori* L. No previous reference to a description of this species has been found.

Genus II. Morator *gen. nov.*

Only one species at present, inducing the disease known as sacbrood of the honey bee. Generic name from Latin *morator*, loiterer. The type, and only, species is *Morator aetatulae spec. nov.*

1. **Morator aetatulae** *spec. nov.* From Latin *aetatula*, early period of life, in reference to attack on immature stages of host, exclusively.

Common name: Honey-bee sacbrood virus.

Host: *APIDAE—Apis mellifera* L., honey bee (immature stages only).

Insusceptible species: *LYMANTRIIDAE—Porthetria dispar* (L.), gypsy moth.

Geographical distribution: United States.

Induced disease: In the honey bee, immature stages only are susceptible; infected larvae die, usually after capping, some of the dead brood being uncapped by the bees. Occasionally caps are punctured. Affected areas of comb are usually small and scattered. Each larva is extended along its cell, head turned upward toward the roof. A larva recently dead appears light yellow, light gray, or light brown, soon darkening to brown or almost black. Cuticle of dead larva tough, permitting extraction of the sac-

like mass without rupture; contents watery with many suspended, fine, brown particles. There are no characteristic intracellular bodies in affected tissues. Dead larvae eventually dry down to form scales that are black and roughened, that separate readily from the cell wall, and that may be lifted out intact. Colonies tend to lose virus spontaneously.

Transmission: By contamination of food. Not by hands, clothing, or tools. Perhaps through water supply of insects.

Thermal inactivation: In water, at 58° C in 10 minutes. In honey, at 70 to 73° C in 10 minutes.

Filterability: Passes Berkefeld and Pasteur-Chamberland filters.

Other properties: Withstands drying 20, not 22, days, exposure to sunlight 7 hours or less, storage in honey a month or more, ½ to 2 per cent aqueous solutions of carbolic acid 3 weeks or more.

Literature: McCray and White, U. S. Dept. Agr., Dept. Bull. 671, 1918; White, U. S. Dept. Agr., Bur. of Entomol., Circ. 169, 1913; U. S. Dept. Agr., Dept. Bull. 92, 1914; *ibid.*, Dept. Bull. 431, 1917.

FAMILY II. BORRELIOTACEAE *FAM. NOV.*

Viruses of the Pox Group, inducing diseases characterized in general by discrete primary and secondary lesions of the nature of macules, papules, vesicles, or pustules.

Key to the genera of family **Borreliotaceae.**

I. Viruses of the Typical Pox-Disease Group.
Genus I. *Borreliota*, p. 1229.
II. Viruses of the Varicella Group.
Genus II. *Briareus*, p. 1233.
III. Viruses of the Herpes Group.
Genus III. *Scelus*, p. 1234.
IV. Viruses of the Foot-and-Mouth-Disease Group.
Genus IV. *Hostis*, p. 1239.
V. Viruses of the Wart-Disease Group.
Genus V. *Molitor*, p. 1240.

Genus I. **Borreliota** *Goodpasture.*

(Science, 77, 1933, 121.)

Viruses of the Typical Pox-Disease Group, inducing diseases characterized by formation of papules, pustules, and scabs, shed with or without scarring. Generic name from *Borrel*, investigator who first discovered the specific granules of fowl pox and Latinized name of the smallest Greek letter, *iota*, signifying smallest particle. The name *Cytoryctes variolae* Guarnieri 1892 was based on intracellular inclusions, Guarnieri bodies, as supposed sporozoan parasites (Calkins, Jour. Med. Res., *11*, 1904, 136–172).

The type species is *Borreliota avium* Goodpasture.

Key to the species of genus **Borreliota.**

I. Affecting domestic fowl.
1. *Borreliota avium.*
II. Affecting man principally, although strains have become adapted to cow, rabbit, etc.
2. *Borreliota variolae.*
III. Affecting swine.
3. *Borreliota suis.*

1. **Borreliota avium** (Lipschütz) Goodpasture. (*Strongyloplasma avium* Lipschütz, in Kolle, Kraus and Uhlenhuth, Handbuch der pathogenen Mikroorganismen, 3 Auft., *8*, 1930, 314; Goodpasture, Science, *77*, 1933, 121.) From Latin *aves*, fowl of the air.

Common names: Fowl-pox virus; also known as poultry-pox virus, chicken-pox virus (but not the virus of the same name attacking man rather than the chicken), or virus of epithelioma contagiosum of fowls; strains have been studied under the names Kikuth's canary virus and pigeon-pox virus.

Hosts: Chicken, turkey, pigeon, goose, duck, guinea fowl, quail, hawk, pheasant, partridge, bunting sparrow, canary. Experimentally, also English sparrow, chick embryo.

Insusceptible species: Man, goat, sheep, mouse, rat, guinea pig.

Geographical distribution: Europe, Asia, North America; perhaps coextensive with the area in which chickens are grown under conditions of domestication.

Induced disease: In chicken, hyperplastic nodular lesions of the skin, diphtheritic membranes in mouth and throat, discharges from eyes and nose; nodules eventually dry up and fall off, usually without leaving scars. Inclusion bodies, known as Bollinger bodies, believed to represent aggregates of minute Borrel bodies or virus particles, leave much grayish-white ash when incinerated; break readily after digestion by 1 per cent trypsin in 0.2 per cent sodium bicarbonate. Borrel bodies coccoid, 0.25 microns in diameter. On chorioallantoic membrane of chick embryo, proliferation and hyperplasia, or necrosis.

Transmission: By contact, perhaps through wound infection. By bloodsucking dipterous insects. Experimentally, by scarification of skin or buccal mucosa; by intravenous, intradermal, subcutaneous, intramuscular, or intraperitoneal inoculation. May be passed in series by nasal instillation in chickens, obvious mucosal changes occurring only occasionally. Experimentally, by mosquitoes (*CULICIDAE*), *Aëdes aegypti* L., *A. stimulans* Walker, *A. vexans* Meigen (as long as 27 days from time of feeding on infective material), and *Culex pipiens* L. (indefinitely after infective feeding, as long as the individual mosquito lives); in *C. pipiens*, the virus has been found also under natural conditions.

Serological relationships: Neutralizing and elementary-body-agglutinating antisera specific. Antivaccinial serum from rabbit ineffective against fowl-pox virus, although neutralizing vaccinia virus.

Immunological relationships: No cross immunity with respect to vaccinia virus in the chicken.

Thermal inactivation: At 60° C in 8 minutes; at 56° C in 30 minutes.

Filterability: Passes Berkefeld V, not Chamberland L_2, filter candle.

Other properties: Drying at room temperature *in vacuo* does not inactivate. Viable after storage at least 24 months at 0 to 4° C, dry.

Strains: A strain known as Kikuth's canary virus has been studied in some detail. When introduced into the rabbit it induces formation of neutralizing antibodies that react strongly with homologous virus, moderately against fowl-pox virus. Antivaccinial serum is ineffective against it. In canaries, it induces proliferation of dermal epithelium with cytoplasmic inclusions, the inflammatory process being characterized by predominantly mononuclear cells with vacuolated cytoplasm; in the lung there is massive accumulation of large mononuclear cells containing the specific cytoplasmic inclusions; the disease is regularly fatal. Passes Berkefeld N filter. Size estimated as 120 millimicrons by centrifugation. (Bechhold and Schlesinger, Ztschr. f. Hyg., *115*, 1933, 354–357; Burnet, Jour. Path. and Bact., *37*, 1933, 107–122; Burnet and Lush, Brit. Jour. Exp. Path., *17*, 1936, 302–307; Gaede, Cent. f. Bakt., I Abt., Orig., *135*, 1935, 342–346; Kikuth and Gollub, *ibid.*, *125*, 1932, 313–320.)

Literature: Andervont, Am. Jour. Hyg., *6*, 1926, 719–754; Brandly and Dunlap, Jour. Am. Vet. Med. Assoc., *95*, 1939, 340–349; Brandly et al., Am. Jour. Vet. Res., *2*, 1941, 190–192; Brody, Cornell Agr. Exp. Sta. (Ithaca). Memoir 195, 1936; Buddingh, Jour. Exp. Med., *67*, 1938, 933-940; Burnet and Lush, Brit. Jour. Exp. Path., *17*, 1936, 302–307; Danks, Am. Jour. Path., *8*, 1932, 711–716; Findlay, Proc. Roy. Soc. London, Ser. B, *102*, 1928, 354–379; Goodpasture and A. M. Woodruff, Am. Jour. Path., *6*, 1930, 699–712; Goodpasture and C. E. Woodruff, *ibid.*, *7*, 1931, 1–8; Irons, Am. Jour. Hyg., *20*, 1934, 329–351; Kligler and Ashner, Proc. Soc. Exp. Biol. and Med., *28*, 1931, 463–465; Kligler et al., Jour. Exp. Med., *49*, 1929, 649–660; Ledingham, Lancet, *221*, 1931 (*2*), 525–526; Ludford and Findlay, Brit. Jour. Exp. Path., 7 1926, 256–264; Matheson et al, Poultry Science, *10*, 1931, 211–223; Megrail, Am. Jour. Hyg., *9*, 1929, 462–465; Nelson, Jour. Exp. Med., *74*, 1941, 203–212; A. M. Woodruff, and Goodpasture, Am. Jour.

Path., 7, 1931, 209–222; C. E. Woodruff, *ibid.*, 6, 1930, 169–174; C. E. Woodruff, and Goodpasture, *ibid.*, 5, 1929, 1–10; 6, 1930, 713–720.

2. **Borreliota variolae** (Lipschütz) Goodpasture. (*Strongyloplasma variolae* Lipschütz, in Kolle, Kraus and Uhlenhuth, Handbuch der pathogenen Mikroorganismen, 3 Aufl., 8, 1930, 317; Goodpasture, Science, 77, 1933, 121.) From New Latin *variola*, smallpox.

Common names: Variola virus, smallpox virus. Most studies of this virus have been concerned with the vaccinia strain; see Strains below.

Hosts: Man, cow and rabbit are susceptible to strains that appear especially adapted to them (see *Strains* below). Experimentally, also chicken (and chick embryo); *Chrysemys marginata*, turtle; guinea pig, horse, pig; *Macaca mulatta* (Zimmermann), rhesus monkey; *M. irus*, cynomolgus monkey; orang-outang; *Macacus fuscatus*.

Geographical distribution: Nearly world-wide, except where excluded by isolation or protective vaccination.

Induced disease: In man, mild to severe smallpox, sometimes with pocks few and discrete but often with pocks numerous and coalescing; onset sudden, 6 to 22 days (average 12) after infection; headache, vomiting, fever, often rashes on body before appearance of the specific eruption, bright red spots becoming vesicular and eventually pustular; the pocks are commonest on face, forearms, wrists, palms of hands, and soles of feet; pustules gradually become flattened scabs and drop off, leaving no scar if superficial and not secondarily infected; in hemorrhagic smallpox there are numerous hemorrhages into the skin and mortality is high, death often preceding formation of pustules; severity of disease and mortality roughly proportional to the amount of eruption on the face.

Transmission: By contact with infected individuals or contaminated articles; perhaps by droplet infection, obvious primary lesions characterizing experimental transmission by scarification but not natural spread.

Serological relationships: Hyperimmune calf serum neutralizes virus. Neutralization depends on an antibody not involved in agglutination and precipitation. Antivaccinial serum gives complement fixation in the presence of variola virus. One agglutinogen (L) labile at 56° C, one (S) stable at 95° C; both are parts of a single protein but can be degraded independently; chymotrypsin destroys activity of S, not L. Increasing neutralization in immune serum and virus mixtures *in vitro* with progressive incubation; partial reactivation on simple dilution. Antivaccinial sera agglutinate Paschen bodies of vaccinia but not Borrel bodies of fowl pox; anti-fowl-pox sera agglutinate Borrel but not Paschen bodies. No cross reactions with herpes virus.

Immunological relationships: In vaccinia-immune swine, protective substances pass *via* colostrum, conveying passive immunity to young for 2 to 3 months after birth. In man, immunity against variola virus is conferred by earlier infection with vaccinia strain. In hen, previous infection with fowl-pox virus does not immunize with respect to vaccinia virus.

Thermal inactivation: At 55° C in 20 minutes.

Filterability: Passes Berkefeld V, not Mandler, filter.

Other properties: Density about 1.16. Sedimentation constant 5000×10^{-13} (corrected to water at 20° C). Retains activity in glycerine best at pH 7.0. 0.1 per cent gelatin delays spontaneous inactivation at 5 to 10° C. Withstands absolute alcohol, ether, acetone, and petroleum ether 1 hour in dry samples at 4° C without decrease in activity. Inactivated without disruption by sonic vibrations of about 8900 cycles per second. Diameter estimated as 125 to 175 millimicrons by filtration; 236 to 252 millimicrons by ultracentrifugation. Electron micrographs show limiting surface

membrane, dense granules (usually 5) within; tendency to rectangular outlines with rounded corners. At least 5.6 per cent of virus is reported to be thymonucleic acid. Contains nitrogen, 15.3 per cent; carbon, 33.7 per cent; phosphorus, 0.57 per cent; phospholipid (lecithin), 2.2 per cent; neutral fat, 2.2 per cent; reducing sugars after hydrolysis, 2.8 per cent; cystine, 1.9 per cent; copper, 0.05 per cent.

Strains: Besides the typical variola strain, var. *hominis* Goodpasture (Science, 77, 1933, 121), several distinctive strains have been studied. A spontaneous cowpox strain differs in some antigens but affords cross immunity with respect to var. *bovis* Goodpasture (*loc. cit.*, 121), vaccinia virus, which in turn immunizes against typical variola virus. A spontaneous rabbit-pox strain, serologically resembling neurovaccine virus, is believed to exist independently in Europe and the United States. The varieties *equi* (horse-pox virus), *porci* (swine strain), and *ovium* (sheep and goat pox virus) have been attributed to this species by Goodpasture (*loc. cit.*, 121). The alastrim strain (causing *variola minor*) differs from the type in producing a relatively mild disease in man and in inducing the formation of a distinctive type of intracellular inclusion in affected tissues.

3. Borreliota suis *spec. nov.* From Latin *sus*, swine.

Common name: Swine-pox virus (not

the vaccinia strain of variola virus in swine).

Host: *SUIDAE—Sus scrofa* L., domestic swine.

Insusceptible species: Rabbit.

Geographical distribution: United States (Iowa).

Induced disease: In swine, locally, reddened hyperemic papules 3 to 7 mm in diameter; papules become briefly vesicular, then change gradually to true pustules, finally forming dark brown to blackish scabs which are shed after a few weeks without scarring; no secondary lesions in hogs free from lice, but in infested animals numerous secondary lesions appear 1 to 2 weeks after primary lesions and are commonly most numerous in the inguinal and axillary regions. Mortality negligible but growth retarded. Virus has been recovered from hog louse after feeding on affected swine.

Transmission: By hog louse, *Haematopinus suis* (*HAEMATOPINIDAE*), probably mechanically. By experimental scarification of skin.

Serological relationships: No reaction with neutralizing sera specific for vaccinia virus.

Immunological relationships: Specific immunity in swine after attack, but no cross immunity with respect to vaccinia virus.

Filterability: Passes Berkefeld V and N filters.

Literature: Csontos and von Nyiredy, Deutsch. tierärztl. Wchnschr., *41*, 1933, 529–532; Schwarte and Biester, Am. Jour. Vet. Res., *2*, 1941, 136–140; Shope, Arch. f. Virusforsch., *1*, 1940, 457–467.

Genus II. **Briareus** *gen. nov.*

Viruses of the Varicella Group, causing diseases characterized by reddened spots and rings in affected tissues, becoming papular or vesicular. Generic name from Latin *Briareus*, name of a hundred-armed giant.

The type species is *Briareus varicellae spec. nov.*

Key to the species of genus **Briareus.**

I. Causing chicken pox and herpes zoster in man.
   1. *Briareus varicellae.*

II. Causing measles in man.
   2. *Briareus morbillorum.*

1. Briareus varicellae *spec. nov.* From New Latin *varicella*, chicken pox.

Common names: Varicella virus, chicken-pox virus; much evidence for identity with so-called herpes-zoster virus has been presented.

Host: *HOMINIDAE—Homo sapiens* L., man.

Insusceptible species: Chick embryo.

Geographical distribution: World-wide.

Induced disease: In man, usually abrupt onset, rash at first macular, soon papular and vesicular; vesicles generally discrete, soon rupturing, healing with scab formation and itching; separation of deeper scabs may leave persistent scars; in severe cases there may be stomatitis, laryngitis, and nasal lesions. In human skin grafted on chorioallantois of chick embryo, experimentally, pustular lesions as in natural disease, with intranuclear acidophilic inclusions; no gross vesiculation.

Transmission: By contact. By spread of droplets. Children in contact with herpes zoster patients sometimes contract varicella.

Serological relationships: Majority of herpes zoster sera that agglutinate zoster antigen also agglutinate elementary bodies of varicella; complement fixation tests also indicate relationship of virus from herpes zoster and varicella. Chicken-pox sera do not flocculate smallpox brain-virus antigen.

Immunological relationships: Children previously having varicella are immune to inoculation with herpes zoster virus.

Literature: Amies, Brit. Jour. Exp. Path., *15*, 1934, 314–320; Brain, *ibid.*, *14*, 1933, 67–73; Bruusgaard, Brit. Jour. Derm. Syph., *44*, 1932, 1–24; Goodpasture and Anderson, Am. Jour. Path., *20*, 1944, 447–453; Havens and Mayfield, Jour. Inf. Dis., *50*, 1932, 242–248; Irons et al., Am. Jour. Hyg., *33*, (B), 1941, 50–55; Kundratitz, Monatsschr. Kinderheilk., *29*, 1925, 516–523; Lipschütz and Kundratitz, Wien. klin. Woch., *38*, 1925, 499–503.

2. **Briareus morbillorum** *spec. nov.* From New Latin *morbilli*, measles.

Common name: Measles virus.

Host: *HOMINIDAE—Homo sapiens* L., man. Experimentally, also *CERCOPITHECIDAE—Macaca mulatta* (Zimmermann), rhesus monkey. *PHASIANIDAE—Gallus gallus* (L.), chick embryo (no lesions, but 30 serial passages).

Geographical distribution: World-wide except in isolated communities.

Induced disease: In man, after incubation period of 7 to 21 days, bright red spots on buccal mucosa, especially near first molar tooth (Koplik's spots) followed by rash on face, head, neck, then arms, trunk, and legs; papules often crescents, lesions usually discrete; rash fades, leaving brownish discoloration and desquamation.

Transmission: By contact. By droplets.

Serological relationships: Convalescent serum is reported to modify the course of the induced disease if administered intravenously in the preeruptive stage.

Immunological relationships: Specific immunity in man after attack.

Thermal inactivation: At 55° C in 15 minutes.

Filterability: Passes Berkefeld N filter candle and Seitz EK disks.

Other properties: Viable at −35° C for at least 4 weeks. Not inactivated by 10 per cent anesthetic ether in 40 minutes.

Literature: Blake and Trask, Jour. Exp. Med., *33*, 1921, 385–412; Gordon and Knighton, Am. Jour. Path., *17*, 1941, 165–176; Hedrich, Am. Jour. Hyg., *17*, 1933, 613–636; Kohn et al., Jour. Am. Med. Assoc., *111*, 1938, 2361–2364; Rake and Shaffer, Jour. Immunol., *38*, 1940, 177–200; Rake et al., Jour Inf. Dis., *69*, 1941, 65–69; Scott and Simon, Am. Jour. Hyg., *5*, 1925, 109–126.

Genus III. Scelus *gen. nov.*

Viruses of the Herpes Group, inducing diseases characterized in general by vesicular primary lesions, sometimes with subsequent involvement of the nervous system. Generic name from Latin *scelus*, rascal.

The type species is *Scelus recurrens spec. nov.*

Key to the species of genus Scelus.

I. In man, cause of so-called fever blisters, herpes febrilis.
  1. *Scelus recurrens.*

II. In swine, cause of pseudorabies.
  2. *Scelus suillum.*

III. In monkey.
  3. *Scelus beta.*

IV. In rabbit, course of the induced disease in nature unknown.
  4. *Scelus tertium.*

V. In sheep, cause of ovine balano-posthitis.
  5. *Scelus ulceris.*

VI. In mice, cause of ectromelia.
  6. *Scelus marmorans.*

VII. In cattle, cause of erosive stomatitis.
  7. *Scelus bovinum.*

1. Scelus recurrens *spec. nov.* From Latin *recurrere*, to recur. Note: The name *Neurocystis herpetii* Levaditi and Schoen (Compt. rend. Soc. Biol., Paris, *96*, 1927, 961) was applied provisionally to the causative microorganism of herpes, in the expectation that future research would show inclusion bodies in affected tissues to be stages in its life cycle.

Common names: Herpes virus, virus of herpes simplex, virus of herpes febrilis (not herpes zoster virus, for which see varicella virus), virus of keratitis dendritica, virus of aphthous stomatitis (of man).

Host: *HOMINIDAE—Homo sapiens* L., man. Experimentally, also rabbit, guinea pig, white mouse, cat, goose, hedgehog, and, though difficult to infect, dog and pigeon. Chick embryo (but not chicken). Also *CERCOPITHECIDAE—Cercocebus fuliginosus* E. Geoffrey, *Macacus cynomolgus*. *CEBIDAE—Cebus olivaceus*.

Insusceptible species: White rat; *Bufo viridis*; *Cercopithecus callithrix*; chicken (except embryo).

Geographical distribution: Probably world-wide.

Induced disease: In man, usually acquired in first three years of life, sometimes as aphthous stomatitis; virus probably retained often through life, sometimes with periodic reappearance of dermal lesions, which are vesicular and heal soon. In white mouse, by experimental inoculation of skin, small inflamed vesicular primary lesions about 5 days after inoculation, usually forming scabs and healing a few days later, but sometimes persisting; if on tail, followed by swelling and paralysis of tail, ascending paralysis and death, or by recovery with acquired immunity; if near head, followed by encephalitis and death; intraperitoneal and sometimes other inoculations immunize; relapse with recurrence of primary lesions rare. In chick embryo, white, opaque, circular or ring-like primary lesions of small size on chorioallantoic membrane, with or without necrotic secondary lesions in liver, heart, lungs, spleen, and kidneys; virus enters membrane 1 to 4 hours after it is dropped on its surface; primary lesions may be counted in 48 hours.

Transmission: By contacts. Experimentally, by skin scarification; in guinea pig, by feeding.

Serological relationships: Distant relationship to pseudorabies virus, *Scelus suillum*, shown by moderate protection against this virus conferred by some anti-herpes sera. No relationship to vaccinia virus or to virus III of rabbits demonstrable by neutralization tests. Specific complement fixation. Neutralizing antibody forms reversible union with virus, at least for a time, though with strong mixtures partial irreversibility finally occurs.

Immunological relationships: Formalinized virus and non-lethal strains of virus immunize specifically. No cross immunity with vaccinia virus.

Thermal inactivation: At 50 to 52° C in 30 minutes, when moist; at 90 to 100° C in 30 minutes, when dry. At 41.5° C in 50 to 80 hours.

Filterability: Passes Berkefeld V filter with slight loss.

Other properties: Diameter, by centrifugation, computed as 180 to 220 millimicrons; by filtration, 100 to 150 millimicrons. Specific gravity, 1.15. Inactivated by repeated freezing and thawing; also by pressure of 3000 atmospheres for 30 minutes. Viable dry at least 18 months at 4° C, in 50 per cent glycerine at least 6 months. Not inactivated at 4° C in 1 per cent aqueous gentian violet. Charged negatively in solutions of hydrogen-ion concentration up to about pH 8. Isoelectric point, pH 7.2 to 7.6. Inactivated by incubation *in vitro* at pH 6 with synthetic vitamin C (ascorbic acid).

Literature: Anderson, Science, *90*, 1939, 497; Am. Jour. Path., *16*, 1940, 137–156; Andervont, Jour. Inf. Dis., *44*, 1929, 383–393; *45*, 1929, 366–385; *49*, 1931, 507–529; Andrewes, Jour. 2. **Scelus suillum** *spec. nov.* From Latin *suillus*, pertaining to swine.

Common names: Pseudorabies virus, mad-itch virus.

Hosts: Domestic cattle, swine, dog, cat, horse, sheep. Experimentally, also rabbit, guinea pig, white rat, white mouse, gray field mouse, duck, chicken, chick embryo; *Macaca mulatta* (Zimmermann), rhesus monkey.

Geographical distribution: France, Germany, Hungary, Holland, Denmark, Switzerland, Siberia, Brazil, United States.

Induced disease: In cattle, licking of affected area, usually somewhere on hindquarters, sudden decrease in milk production in dairy animals, violent rubbing, biting, and gnawing of lesion; swelling and discoloration of affected parts with oozing of serosanguineous fluid; grinding of teeth and excessive salivation in some individuals; death, preceded by clonic convulsions, violent tossing of head, and shallow respiration, usually 36 to 48 hours after onset. In pig, mild but highly contagious disease; slight nerve-cell degeneration, predominance of vascular and interstitial lesions.

Transmission: By contact in swine, not in cattle. By feeding in cats, brown rats, and swine.

Serological relationships: Cross neutralization between constituent strains. Anti-herpes sera protect in some cases against small, but constantly infective, doses of pseudorabies virus.

Literature: Aujeszky, Cent. f. Bakt. I Abt., Orig., *32*, 1902, 353–357; F. B. Bang, Jour. Exp. Med., *76*, 1942, 263–270;

O. Bang, Acta path. et microbiol. Scand., Suppl., *11*, 1932, 180–182; Carini and Maciel, Bull. Soc. Path. exot., *5*, 1912, 576–578; Følger, Acta path. et microbiol. Scand., Suppl., *11*, 1932, 182–187; Glover, Brit. Jour. Exp. Path., *20*, 1939, 150–158; Gowen and Schott, Am. Jour. Hyg., *18*, 1933, 674–687; Hurst, Jour. Exp. Med., *58*, 1933, 415–433; *59*, 1934, 729–749; *63*, 1936, 449–463; Köves and Hirt, Arch. wissensch. u. prakt. Tierheilk., *68*, 1934, 1–23; Morrill and Graham, Am. Jour. Vet. Res., *2*, 1941, 35–40; Brit. Jour. Exp. Path., *15*, 1934, 372–380; Shope, Proc. Soc. Exp. Biol. and Med., *30*, 1932, 308–309; Jour. Exp. Med., *54*, 1931, 233–248; *57*, 1933, 925–931; *62*, 1935, 85–99, 101–117, Traub, *ibid.*, *58*, 1933, 663–681; *61*, 1935, 833–838.

3. **Scelus beta** *spec. nov.* From *beta*, second letter of Greek alphabet, in reference to common name.

Common name: B virus.

Hosts: *HOMINIDAE—Homo sapiens* L., man. *CERCOPITHECIDAE—Macaca mulatta* (Zimmermann), rhesus monkey. Experimentally, also *LEPORIDAE—Oryctolagus cuniculus* (L.), rabbit. *CAVIIDAE—Cavia porcellus* (L.), guinea pig.

Geographical distribution: United States (from captive monkeys and man).

Induced disease: In man, local and relatively insignificant lesion on bitten part, later flaccid paralysis of legs, urinary retention, ascending paralysis, and death by respiratory failure. In *Macaca mulatta*, experimentally by intracutaneous injection, hemorrhagic or vesiculo-pustular lesions without later involvement of central nervous system but with subsequent acquired immunity. Acidophilic intranuclear inclusions in lesions.

Transmission: To man, by bite of monkey. To monkey, experimentally, by injection.

Literature: Burnet et al., Austral. Jour. Exp. Biol. and Med. Sci., *17*, 1939, 35–40, 41–51; Sabin, Brit. Jour. Exp. Path., *15*, 1934, 248–268, 268–279, 321–334; Sabin and Hurst, *ibid.*, *16*, 1935, 133–148; Sabin and Wright, Jour. Exp. Med., *59*, 1934, 115–136.

4. **Scelus tertium** *spec. nov.* From Latin *tertius*, third.

Common name: Virus III of rabbits.

Host: *LEPORIDAE—Oryctolagus cuniculus* (L.), domestic rabbit.

Insusceptible species: No obvious disease in inoculated guinea pig, white mouse, monkey (*Macaca mulatta* Zimmermann), rat, or man; hence the assumption that these are naturally immune, but they may be merely tolerant or klendusic.

Geographical distribution: United States (apparently spontaneous in some individuals of the laboratory rabbit).

Induced disease: In domestic rabbit, experimentally, after incubation period of 4 to 6 days, failure to eat, loss of weight, occasionally diarrhea and temperatures of 104 to 107° F; small, superficial, red spots and papules on skin at site of inoculation; local infiltration of tissues with endothelial leucocytes, swelling of involved epithelial cells; nuclear inclusions present in endothelial leucocytes and some other cells; disease not fatal; virus in circulating blood only during early stages; recovery in a few days without scar formation but with development of specific immunity. The course of the natural disease, presumed to occur in rabbits, is still unknown.

Transmission: Experimentally, by injection of filtrates from diseased tissues; on several occasions also from blood or tissues of apparently normal rabbits.

Serological relationships: Specific neutralizing substances occur in the serum of recovered rabbits.

Immunological relationships: Specific immunity but no cross reactions with vaccinia or herpes viruses.

Thermal inactivation: In 10 minutes at 55° C, but not in 30 minutes at 45° C.

Filterability: Passes Berkefeld V and N filters; passes L_2 filter candle.

Other properties: Viable at least 6

weeks in 50 per cent glycerine and 16 months dried when frozen, and stored on ice.

Literature: Andrewes, Brit. Jour. Exp. Path., *10*, 1929, 188–190, 273–280; Jour. Path. and Bact., *33*, 1930, 301–312; *50*, 1940, 227–234; Rivers and Stewart, Jour. Exp. Med., *48*, 1928, 603–613; Rivers and Tillett, *ibid.*, *39*, 1924, 777–802; *40*, 1924, 281–287; Topacio and Hyde, Am. Jour. Hyg., *15*, 1932, 99–124.

5. **Scelus ulceris** *spec. nov.* From Latin *ulcus*, sore spot.

Common name: Ovine balano-posthitis virus.

Host: *BOVIDAE—Ovis aries* L., sheep.

Geographical distribution: United States, Australia.

Induced disease: In sheep, ulceration with scab production: lesions most severe on prepuce and vulva; in the male, the penis may be involved, usually only with mild inflammation, but if accompanied by paraphimosis there may be extensive ulceration and heavy scab formation.

Transmission: Venereally. Experimentally, by inoculation of prepuce.

Filterability: Passes Berkefeld N and W filters, a 7 lb Mandler candle, and a 3½ per cent collodion membrane.

Literature: Tunnicliff and Matisheck, Science, *94*, 1941, 283–284.

6. **Scelus marmorans** *spec. nov.* From Latin *marmorare*, to marble, in reference to mottling of spleen and liver in host.

Common name: Ectromelia virus.

Hosts: *MURIDAE—Mus musculus* L., white mouse. Esperimentally, also *MURIDAE—Rattus norvegicus* (Berkenhout), rat (infection inapparent). Also, *PHASIANIDAE—Gallus gallus* (L.), chick embryo (12-day-old White Leghorn chick embryo at 36 to 37° C; less satisfactory results at higher temperatures of incubation or in embryos in spring eggs). Derived strains of this virus infect rabbit and guinea pig, not susceptible to original virus from mouse.

Geographical distribution: England.

Induced disease: In white mouse, spleen mottled, liver edges translucent, peritoneal fluid increased in amount; loss of weight; later, cutaneous lesions on foot or elsewhere; affected foot swells, becomes moist, scabbed, then recovers or dries up and separates from the skin at limit of original swelling; in acute disease, death without gross lesions, or, at autopsy, gut dark red, liver dirty gray, soft, bloodless, sometimes mottled, spleen necrotic; inclusion bodies most numerous in lesions of the skin, round or oval, 4 to 13 microns long, without internal differentiation; very young mice probably become infected without developing apparent disease and remain carriers for some time. In rat, inapparent infection; after initial increase of virus, circulating antibodies appear and immunity to reinfection is established.

Transmission: In mouse, by contact. In rat, experimentally, by intranasal inoculation.

Serological relationships: Neutralizing antibodies occur in convalescent mouse serum. Immune sera from the guinea pig specifically agglutinate elementary bodies obtained from infected skin of the white mouse.

Immunological relationships: Recovered mice are solidly immune to many lethal doses.

Thermal inactivation: At 55° C in 30, not in 10, minutes.

Filterability: In broth, passes Mandler, Pasteur-Chamberland L_2, and Berkefeld N filters.

Other properties: Survives drying 6 months, freezing (−10° C) 2 months, 50 per cent glycerine 5 months at least. Resists 1 per cent phenol 20, not 40, days. Size, estimated by filtration, 100 to 150 millimicrons; by ultraviolet-light photography, 130 to 140 millimicrons.

Literature: Barnard and Elford, Proc. Roy. Soc. London, Ser. B, *109*, 1931, 360–380; Baumgartner, Cent. f. Bakt., I Abt., Orig., *133*, 1935, 282–289; Burnet and Lush, Jour. Path. and Bact., *42*, 1936, 469–476; *43*, 1936, 105–120; Jahn, Arch. f. Virusforsch., *1*, 1939, 91–103; Kikuth and

Gönnert, Arch. f. Virusforsch., *1*, 1940, 295–312; Marchal, Jour. Path. and Bact., *33*, 1930, 713–728; McGaughey and Whitehead, *ibid.*, *37*, 1933, 253–256; Paschen, Cent. f. Bakt., I Abt., Orig., *135*, 1936, 445–452.

7. **Scelus bovinum** *spec. nov.* From Latin *bovinus*, of ox, bull, or cow.

Common name: Erosive-stomatitis virus.

Host: *BOVIDAE—Bos taurus* L., domestic cattle. Experimentally, also chorioallantoic membrane of developing hen's egg.

Insusceptible species: *CAVIIDAE—Cavia porcellus* (L.), guinea pig. (In rats, rabbits, mice, sheep, no reaction has been noted after inoculation.)

Geographical distribution: South Africa (Natal); perhaps Ireland (Armagh-disease virus).

Induced disease: In young domestic cattle, lesions on tongue, dental pad, and lips pearl-like at first, then breaking down to form superficial erosions, with white glistening base and red border. Lesions may coalesce to form large, ragged, eroded areas, healing uneventfully with scar formation. No foot lesions; no excessive salivation; no "hotness" of mouth; no systemic disturbances.

Transmission: Spreads slowly, mainly to animals less than three years old, probably by contact. Experimentally, by injection into dental pads, lips, or tongue.

Filterability: Passes Gradocol membrane of about 400 millimicron average pore diameter.

Other properties: Viable after at least 11 days at room temperature, 21 days at refrigerator temperature, 6 weeks frozen and dried in horse-serum saline.

Literature: Mason and Neitz, Onderstepoort Jour. Vet. Sci. and Anim. Indust., *15*, 1940, 159–173.

Genus IV. Hostis *gen. nov.*

Viruses of the Foot-and-Mouth Disease Group, inducing diseases mainly characterized by vesicular lesions. Generic name from Latin *hostis*, enemy or stranger.

The type species is *Hostis pecoris spec. nov.*

Key to the species of genus Hostis.

I. Infecting cattle and other animals with cloven hoofs; horse immune or highly resistant.

1. *Hostis pecoris.*

II. Infecting horse readily.

2. *Hostis equinus.*

1. **Hostis pecoris** *spec. nov.* From Latin *pecus*, cattle.

Common names: Foot-and-mouth disease virus; Virus der Maul- und Klauenseuche.

Hosts: Cow, pig, sheep, goat, reindeer, bison. Experimentally, also guinea pig, rabbit, rat.

Insusceptible species: Chick embryo (chorioallantois); horse (immune or very resistant).

Induced disease: In cow, after incubation period of 2 to 4 days or more, fever, vesicular lesions on tongue, lips, gums, hard palate and feet, soon rupturing; salivation, lameness, generally recovery.

Transmission: Spread rapid, source of infection often obscure; saliva is infective before lesions become obvious.

Thermal inactivation: At 70° C, not at 60° C, in 15 minutes.

Filterability: Passes Seitz, Berkefeld V and N, and Chamberland L_{11} filters.

Strains: Three strains, A, O and C, are immunologically distinct from each other.

Other properties: Particle calculated to be about 20 millimicrons in diameter by centrifugation data, 8 to 12 millimicrons in diameter by filtration; may be separated from mixtures with the larger equine vesicular stomatitis virus by differential filtration. Viable after drying

in vacuo, at least a week at −4 to 0° C. Readily destroyed by 1 to 2 per cent sodium hydrate or above pH 11. Soon inactivated near pH 6.0, but moderately stable at pH 2.0 to 3.0; optimum condition for storage at pH 7.5 to 7.7 in absence of air; return from 3.0 to 7.5 inactivates, however.

Literature: Elford and Galloway, Brit. Jour. Exp. Path., *18*, 1937, 155–161; Galloway and Elford, *ibid.*, *14*, 1933, 400–408; *16*, 1935, 588–613; *17*, 1936, 187–204; Galloway and Schlesinger, Jour. Hyg., *37*, 1937, 463–470; Hare, Jour. Path. and Bact., *35*, 1932, 291–293; Loeffler and Frosch, Cent. f. Bakt., I Abt., *23*, 1898, 371–391; Matte and Sanz, Bull. Soc. Path. Exot., *14*, 1921, 523–529; Olitsky and Boez, Jour. Exp. Med., *45*, 1927, 673–683, 685–699, 815–831, 833–848; Pyl, Ztschr. f. physiol. Chemie, *226*, 1934, 18–28; Pyl and Klenk, Cent. f. Bakt., I Abt., Orig., *128*, 1933, 161–171; Schlesinger and Galloway, Jour. Hyg., *37*, 1937, 445–462.

2. **Hostis equinus** *spec. nov.* From Latin *equinus*, pertaining to horses.

Common names: Vesicular-stomatitis virus, equine vesicular stomatitis virus.

Hosts: Horse, domestic cattle. Experimentally, also guinea pig, swine, white mouse, rabbit (relatively resistant), chick embryo; *Macaca mulatta* (Zimmermann), rhesus monkey; *M. irus*, cynomolgus monkey.

Insusceptible species: Chicken (except embryo).

Geographical distribution: United States (Indiana, New Jersey).

Induced disease: In horse, resembles foot-and-mouth disease of cattle; reddened patches on buccal mucosa, moderate fever, salivation, followed by appearance of vesicles, especially on tongue, filled with clear or yellowish fluid; vesicles often coalesce and soon rupture leaving an eroded surface which heals soon in the absence of complications. Experimentally, in chorioallantois of developing chick embryo, primary lesions involve moderate ectodermal proliferation, degeneration, necrosis; mesodermal inflammation; slight endodermal proliferation.

Serological relationships: Strains isolated in different localities give antisera capable of neutralizing heterologous isolates of virus, but homologous antisera neutralize in higher dilutions than do heterologous antisera.

Immunological relationships: No cross immunity with respect to equine encephalomyelitis virus.

Filterability: Passes Seitz filter.

Other properties: May be separated from mixtures with foot-and-mouth disease virus by propagation on chorioallantoic membrane of chick embryo, which will not support increase of the latter virus. Inactivated by 1:50,000 methylene blue in 2 mm layer 13 cm from 300 candle-power lamp in 60 minutes but not in 20 minutes. Particle estimated on the basis of filtration data to be 70 to 100 millimicrons in diameter; 60 millimicrons in diameter by centrifugation. Not destroyed by acidifying to pH 3 and returning to pH 7.5 (difference from foot-and-mouth disease virus).

Literature: Burnet and Galloway, Brit. Jour. Exp. Path., *15*, 1934, 105–113; Cox and Olitsky, Proc. Soc. Exp. Biol. and Med., *30*, 1933, 653–654; Cox et al., *ibid.*, *30*, 1933, 896–898; Elford and Galloway, Brit. Jour. Exp. Path., *18*, 1937, 155–161; Galloway and Elford, *ibid.*, *14*, 1933, 400–408; *16*, 1935, 588–613; Mohler, Jour. Am. Vet. Med. Assoc., *52*, 1918, 410–422; Olitsky et al., Jour. Exp. Med., *59*, 1934, 159–171; Pyl, Ztschr. f. physiol. Chemie, *226*, 1934, 18–28; Sabin and Olitsky, *ibid.*, *66*, 1937, 15–34, 35–57; *67*, 1938, 201–228, 229–249; Syverton et al., Science, *78*, 1933, 216–217.

Genus V. **Molitor** *gen. nov.*

Viruses of the Wart-Disease Group, inducing diseases mainly characterized by tissue proliferation without vesicle or pustule formation. Generic name from Latin *molitor*, contriver.

The type species is *Molitor verrucae spec. nov.*

Key to the species of genus **Molitor.**

I. Affecting man.
- 1. *Molitor verrucae.*
- 2. *Molitor hominis.*

II. Affecting cow.
- 3. *Molitor bovis.*

III. Affecting dog.
- 4. *Molitor buccalis.*

IV. Affecting chicken.
- 5. *Molitor tumoris.*

V. Affecting rabbit
- 6. *Molitor gingivalis.*
- 7. *Molitor sylvilagi.*
- 8. *Molitor myxomae.*

1. **Molitor verrucae** *spec. nov.* From Latin *verruca*, wart.

Common name: Common-wart virus.

Hosts: *HOMINIDAE—Homo sapiens* L., man. Perhaps also *BOVIDAE—Bos taurus* L., cow. *CANIDAE—Canis familiaris* L., dog.

Induced disease: Experimentally in man, incubation period long, 4 weeks to 6 or more months; initially acanthosis (overgrowth of prickle cell layer of epidermis) and flattening of the papillae; later, interpapillary hypertrophy, inflammation, and marked hyperkeratosis.

Transmission: By contact; in some cases, venereally. Experimentally, by skin scar fication.

Filterability: Passes Berkefeld N filter.

Literature: Ciuffo, Giorn. ital. d. malattie veneree e d. pelle, *48*, 1907, 12–17; Kingery, Jour. Am. Med. Assoc., *76*, 1921, 440–442; Payne, Brit. Jour. Dermat., *3*, 1891, 185–188; Schultz, Deutsch. med. Wchnschr., *34*, 1908, 423; Serra, Giorn. ital. d. malattie veneree e d. pelle, *65*, 1924, 1808–1814; Ullmann, Acta oto-laryngologica, *5*, 1923, 317–334; Wile and Kingery, Jour. Am. Med. Assoc., *73*, 1919, 970–973.

2. **Molitor hominis** *comb. nov.* (*Strongyloplasma hominis* Lipschütz, Arch. Dermat. u. Syph., *107*, 1911, 395.) From Latin *homo*, man.

Common name: *Molluscum contagiosum* virus.

Host: *HOMINIDAE—Homo sapiens* L., man.

Geographical distribution: Perhaps essentially world-wide.

Induced disease: In man, experimentally, prodromal period may be 14 to 50 days, lesions at first like pimples, becoming red, painful, swollen, developing into small tumors covered with stretched and shiny skin; lesions commonest on face, arms, buttocks, back, and sides, healing spontaneously. Inclusions within epithelial cells, known as molluscum bodies, measure 9 to 24 microns in diameter when approximately spherical, 24 to 27 microns in width and 30 to 37 microns in length when elongated; they contain elementary bodies about 0.3 micron in diameter. The outer envelope of the molluscum body is of carbohydrate.

Transmission: By contact. By fomites.

Filterability: Passes Chamberland L_1 and Berkefeld V filters.

Literature: Goodpasture and King, Am. Jour. Path., *3*, 1927, 385–394; Goodpasture and Woodruff, *ibid.*, *7*, 1931, 1–8; Juliusberg, Deutsch. med. Wchnschr.,

31, 1905, 1598–1599; Lipschütz, Arch. Dermat. u. Syph., *107*, 1911, 387–396; in Kolle, Kraus and Uhlenhuth, Handbuch der Pathogenen Mikroorganismen, *8*, 1930, 1031–1040; Van Rooyen, Jour. Path. and Bact., *46*, 1938, 425–436; *49*, 1939, 345–349; Wile and Kingery, Jour. Cutan. Dis., 37, 1919, 431–446.

3. **Molitor bovis** *spec. nov.* From Latin *bos*, cow.

Common name: Cattle-wart virus.

Host: *BOVIDAE—Bos taurus* L., domestic cattle.

Geographical distribution: United States.

Induced disease: In cattle, especially about head, neck, and shoulders in young animals, on udders in cows, affected skin thickened at first, then rough, nodular; warts sometimes become large and pendulous, adversely affecting growth of host; they sometimes become cauliflower-like tumors several inches in diameter; spontaneous regression is not infrequent. Hides from affected animals are reduced in value.

Transmission: Believed to be through injuries to skin when the injured part comes in contact with warty animals or with rubbing posts, chutes, fences, buildings, or other structures with which affected animals have come in contact previously. Experimentally, by skin inoculations, especially in animals under 1 year of age.

Filterability: Passes Berkefeld N filter.

Literature: Creech, Jour. Agr. Res., *39*, 1929, 723–737; U. S. Dept. Agr., Leaflet 75, 1931, 1–4.

4. **Molitor buccalis** *spec. nov.* From Latin *bucca*, cheek.

Common name: Canine oral-papillomatosis virus.

Host: *CANIDAE—Canis familiaris* L., dog.

Insusceptible species: Cat, rabbit, guinea pig, rat, mouse; *Macaca mulatta* (Zimmermann), rhesus monkey.

Induced disease: In young dog, experimentally, about 1 month after inoculation of buccal membrane by scarification, pale, smooth elevations, becoming gradually more conspicuous and roughened; finally a mass of closely packed papillae is formed. Regression with subsequent immunity is frequent; no scars are left on regression. Secondary warts often appear in other parts of the mouth 4 to 6 weeks after primary warts have first been observed.

Transmission: Experimentally by skin scarification.

Serological relationships: Not inhibited by antiserum effective against common-wart virus of man.

Thermal inactivation: At some temperature between 45 and 58° C in 1 hour.

Filterability: Passes Berkefeld N filter.

Other properties: Viable after freezing and drying, if stored dry in icebox, at least 63 days; in storage in equal parts of glycerine and 0.9 per cent NaCl solution at least 64 days.

Literature: DeMonbreun and Goodpasture, Am. Jour. Path., *8*, 1932, 43–56; M'Fadyean and Hobday, Jour. Comp. Path. and Therap., *11*, 1898, 341–344; Penberthy, *ibid.*, *11*, 1898, 363–365.

5. **Molitor tumoris** *spec. nov.* From Latin *tumor*, swelling.

Common names: Fowl-sarcoma virus, Rous chicken-sarcoma virus.

Hosts: *PHASIANIDAE—Gallus gallus* (L.), chicken. Experimentally, also pheasant (serial transfer difficult) and duck (by cell transfer only but filtrates from duck infect injected chicken).

Insusceptible species: Turkey, guinea fowl (both immune to filtrates but capable of supporting tumor line if alternated in a series with common fowl hosts); geese.

Induced disease: In hen, originally found in an adult, pure-bred hen of Barred Plymouth Rock variety. Experimentally transmitted, a circumscribed nodule soon becomes evident at site of implantation; later this becomes necrotic or cystic at its center; as growth enlarges, host becomes emaciated, cold, somnolent, and finally dies; discrete metastases are often found in lungs, heart, and liver. Parent cell of sarcoma is claimed to be

the normal histiocyte, but virus in the affected fowl is not confined to the sarcoma, being widespread in the body in spleen, liver, muscle, brain, etc. In the chick embryo, serial passage is feasible on the egg membrane, in which focal lesions involve only ectodermal tissue.

Transmission: By injection of affected fowl cells or filtrates. Certain transmissible tar-induced sarcomas, not infecting by filtrates, nevertheless induce the formation of antibodies capable of neutralizing this virus. An inhibitor of the virus extracted from tumors appears to be a protein, inactivated at 65° C, but not at 55° C, in 30 minutes and destroyed by trypsin in 3 to 5 hours at pH 8. Oleic acid also may act as an inhibitor. No spontaneous transmission in chickens kept together.

Serological relationships: Particles sedimented by centrifugal force 20,000 to 30,000 times gravity are specifically agglutinated by sera of fowls bearing corresponding tumor. At least one antigen in tumors of hen and duck not in healthy birds; this one fixes complement and gives cross reactions with Rous, Mill Hill 2, Fujinami, and RFD2 tumors. Virus injected into goats produces two antibodies but only one if previously heated; the antibody to the heat-stable constituent requires complement to neutralize virus; the only antibody produced in ducks does not require complement to neutralize.

Thermal inactivation: At or below 54° C in 20 minutes.

Filterability: Passes Berkefeld V and no. 5 (medium) filters.

Other properties: Particle size estimated as about 100 millimicrons (but some say 50 or even 15 millimicrons) in diameter by filtration through graded membranes, about 70 millimicrons (molecular weight 140,000,000) by ultracentrifugation. Contains 8.5 to 9.0 per cent nitrogen, 1.5 per cent phosphorus. Protein tests positive. Feulgen reaction for thymonucleic acid absent; 10 to 15 per cent of the protein may be nucleic acid, probably of ribose type. Pentose present. Virus believed to be of globulin nature or attached to globulin particles (Lewis and Mendelsohn, Am. Jour. Hyg., *12*, 1930, 686–689). Viable indefinitely in dried spleen as in dried sarcoma tissues.

Strains: Several strains have been studied in addition to the original Rous sarcoma no. 1 strain; immunological relationships have been shown between the original strain, the des Ligneris sarcoma strain, the Fujinami sarcoma strain, the fibrosarcoma MH1 and endothelioma MH2 strains; other isolates also have shown serological interrelationships.

Literature: Amies, Jour. Path. and Bact., *44*, 1937, 141–166; Amies et al., Am. Jour. Cancer, *35*, 1939, 72–79; Andrewes, Jour. Path. and Bact., *34*, 1931, 91–107; *35*, 1932, 407–413; *37*, 1933, 17–25, 27–44; *43*, 1936, 23–33; Claude, Jour. Exp. Path. and Bact., *34*, 1931, 116–117 (Abst.); Haddow, *ibid.*, *37*, 1933, 149–155; Helmer, Jour. Exp. Med., *64*, 1936, 333–338; Keogh, Brit. Jour. Exp. Path., *19*, 1938, 1–9; Ledingham and Gye, Lancet, *228*, 1935 (*1*), 376–377; Lewis and Mendelsohn, Am. Jour. Hyg., *12*, 1930, 686–689; des Ligneris, Am. Jour. Cancer, *16*, 1932, 307–321; McIntosh, Jour. Path. and Bact., *41*, 1935, 215–217; Mellanby, Jour. Path. and Bact., *46*, 1938, 447–460; *47*, 1938, 47–64; Mendelsohn et al., Am. Jour. Hyg., *14*, 1931, 421–425; Purdy, Brit. Jour. Exp. Path., *13*, 1932, 473–479; Rous, Jour. Exp. Med., *13*, 1911, 397–411.

6. **Molitor gingivalis** *spec. nov.* From Latin *gingiva*, gum.

Common name: Rabbit oral-papillomatosis virus.

Hosts: *LEPORIDAE—Oryctolagus cuniculus* (L.), domestic rabbit. Experimentally, also *Lepus americanus*

Erxleben, snowshoe hare; *L. californicus* Gray, jack rabbit; *Sylvilagus* sp., cottontail rabbit.

Geographical distribution: United States.

Induced disease: In rabbit, benign papillomas, having the form of small, discrete, gray-white, sessile or pedunculated nodules, usually multiple, on lower surface of tongue or, less frequently, on gums or floor of mouth.

Transmission: Perhaps by mother to suckling young, with a latent period before onset of disease. Not highly contagious, if contagious at all, in old animals. Experimentally by puncture of tissues in the presence of virus.

Immunological relationships: Specific immunity develops as a result of disease, but no cross immunity with respect to rabbit-papilloma virus, which differs also in failing to act on oral mucosa.

Filterability: Passes Berkefeld V and N filters.

Literature: Parsons and Kidd, Jour. Exp. Med., *77*, 1943, 233–250.

7. **Molitor sylvilagi** *spec. nov.* From New Latin *Sylvilagus*, generic name of cottontail rabbit.

Common names: Rabbit papilloma or papillomatosis virus, rabbit wart virus.

Hosts: *LEPORIDAE—Sylvilagus* sp., cottontail rabbit. Experimentally, also *LEPORIDAE — Oryctolagus cuniculus* (L.), domestic rabbit.

Geographical distribution: United States.

Induced disease: In cottontail rabbit, at first minute elevations along lines of scarification; later solid masses of wrinkled keratinized tissue, 3 to 4 millimeters in thickness; eventually cornified warts, striated perpendicularly at top, fleshy at base, 1 to 1.5 cm in height; regression rare; natural papillomas become malignant occasionally. In domestic rabbit, experimentally, blood antibody remains low but virus is always masked, preventing serial passage; discrete lesions on skin permit quantitative tests; tarring causes localization of virus from blood stream; papillomas give rise to malignant acanthomatous tumors by graded continuous alteration; metastasis frequent; transplantation to new hosts successful in series; antibody specific for the virus is formed continuously in the transplanted growths although virus is not directly demonstrable by subinoculation from them; malignant growths appear more promptly and frequently where epidermis has been tarred long; virus appears specific for epithelium of skin; growths disappear if treated with X-rays, 3600 r at one time or fractionally; 60 per cent are cured with 3000 r, but 2000 r ineffective.

Transmission: Experimentally, by scarification of skin. Abnormal susceptibility to infection is noted in rabbit skin treated with 0.3 per cent methylcholanthrene in benzene or equal parts of turpentine and acetone.

Serological relationships: Specific neutralization, reversible on dilution. Complement fixation specific, with virus particle as antigen; no cross reaction with antisera for vaccinia, herpes, fibroma, or myxoma viruses. Precipitates occur in properly balanced mixtures of virus and specific antiserum; virus and antibody in both free and neutralized states are present in both soluble and insoluble phases of these suspensions.

Immunological relationships: Intraperitoneal injections immunize specifically. Rabbits immunized to fibroma and myxoma viruses are susceptible to rabbit papilloma virus.

Thermal inactivation: At 70° C, not at 65 to 67°C, in 30 minutes; in 0.9 per cent sodium chloride solution at 65 to 66° C, time not stated.

Filterability: Passes Berkefeld V, N, and W filters; particle size calculated as 23 to 35 millimicrons by filtration as compared with 32 to 50 millimicrons by centrifugation and 44.0 millimicrons by measurement of electron micrographs, which show the particle to be approximately spherical in shape.

Other properties: Infectious particle has sedimentation constant S_{20} = *ca.* 250 × 10^{-13} cm per sec. per dyne; usually there is a secondary boundary at about 375 × 10^{-13}. Isoelectric point between pH 4.8 and 5.1. Maximum absorption at about 2750 Å. Contains thymus nucleic acid about 6.8 to 8.7 per cent; maximum absorption of nucleic acid at about 2630 Å.

Literature: Beard et al., Jour. Inf. Dis., *65*, 1939, 43–52; *69*, 1941, 173–192; Bryan and Beard, *ibid.*, *65*, 1939, 306–321; Friedewald, Jour. Exp. Med., *75*, 1942, 197–220; Hoyle, Jour. Path. and Bact., *50*, 1940, 169–170; Kidd, Jour. Exp. Med., *58*, 1933, 607–624; *65*, 1937, 219–231; Syverton et al., *ibid.*, *73*, 1941, 243–248; Taylor et al., Jour. Inf. Dis., *71*, 1942, 110–114.

8. **Molitor myxomae** (Aragão) *comb. nov.* (*Chlamidozoon myxomae* Aragão, Brazil-Med., *25*, 1911, 471; name later abandoned by its original author in favor of *Strongyloplasma myxomae* Aragão, Mem. Inst. Oswaldo Cruz. *20*, 1927, 231 and 243. The name *Sanarellia cuniculi* Lipschütz, Wien. klin. Wochenschr., *40*, 1927, 1103, was based on the supposed causative organism, defined as varying in size between the size of chlamydozoa and of large cocci; it is not clear whether the structures observed and named were virus particles or not.) From New Latin *myxoma*, a kind of soft tumor, from nature of induced lesion.

Common names: Myxoma virus, *virus myxomatosum*.

Hosts: *LEPORIDAE—Oryctolagus cuniculus* (L.), domestic rabbit. Experimentally, also *Sylvilagus* sp., cottontail rabbit; jack rabbit (once in many trials); *Lepus brasiliensis* (resistant and rarely infected). Also chick embryo and duck embryo.

Insusceptible species: *Lepus californicus* Gray, black-tailed jack rabbit; *L. americanus* Erxleben, varying hare; *Sylvilagus transitionalis* Bangs, cottontail; horse, sheep, goat, cattle, dog (but one reported infected), guinea pig, rat, mouse, fowl, pigeon, duck, cat, hamster, monkey; man (but some conjunctival pain and swelling).

Geographical distribution: South America (Brazil, Uruguay, Argentina), United States (California).

Induced disease: In domestic rabbit, a disease (*myxomatosis cuniculi*) almost always fatal at ordinary room temperatures but not at 36 to 42° C, lesions fewer and regressing after 6 to 8 days at these higher temperatures in most animals. At ordinary temperatures, nodules (edematous tumors) in skin near eyes, nose, mouth, ears, and genitalia; edema of eyelids; conjunctivitis with purulent discharge if skin around eyes is involved. Later marked dyspnea, stertorous breathing, cyanosis, asphyxia. Animals usually die within 1 to 2 weeks of infection. Virus enters bloodstream and invades nervous system at random through walls of blood vessels. Discharges from nose, eyes, and the serous exudates from affected tissues are infectious; urine and feces are not. There are cytoplasmic inclusions in affected epidermal cells. In chick embryo, experimentally, intense inflammation, eventual impairment of circulation and necrosis locally; growth best if embryo is grown at 33 to 35° C and chilled to 25° C for 12 to 18 hours before or after inoculation, lesions being linear and associated with capillaries in ectoderm; virus infects and is recoverable from embryo and depresses hatch.

Transmission: By contact with diseased rabbits or cages recently occupied

by them. Through air for a few inches. Rarely by feeding. Experimentally, by rubbing conjunctiva with a bit of infected tissue or with a platinum loop contaminated from diseased conjunctiva; has been recovered from flies. By injection. By flea, *Ctenopsylla felis* (*PULICIDAE*), rarely.

Serological relationships: An attack of the disease induces the formation of neutralizing antibodies. Cross neutralization by antisera to myxoma and fibroma strains. Complement is fixed with myxoma virus as test antigen in the presence of antisera to myxoma or fibroma strains. Serum of rabbit inoculated with a soluble antigen, a heat-labile protein with isoelectric point near pH 4.5, agglutinates myxoma elementary bodies. A second soluble antigen, also heat labile, appears distinct, inhibiting its own antibody even after inactivation of its precipitating power by exposure at 56° C.

Immunological relationships: Myxoma-recovered domestic rabbits become immune to reinfection; fibroma-strain-recovered animals, although partially immunized, still support myxoma-strain virus introduced into the testicle. Heat-inactivated virus (60° C for 30 minutes) tends to immunize if given intradermally; there is then an allergic local response, less severe generalized disease, delayed death or recovery. If fibroma virus precedes myxoma virus by 48 to 96 hours, there is marked protection.

Thermal inactivation: At 55° C in 10 minutes; at 50° C in 1 hour. A substance thermostabile for 30 minutes at 60 to 75° C, but not at 90° C, is itself unable to produce myxomatous changes after the heat treatment but may do so in combination with fibroma virus, and transmissible myxoma virus is then reconstituted. Although it is supposed by some that this indicates the transformation of fibroma-strain virus into myxoma-strain virus, the possibility that heat-modified myxoma-strain virus is reactivated has not been eliminated.

Filterability: Passes Berkefeld V and N filters; not Chamberland L_5 or L_7 filters.

Other properties: Inactivated above pH 12.0 and below pH 4.0. Withstands drying. Viable at least 3 months at 8 to 10° C.

Strains and substrains: A strain from cottontail rabbits (*Sylvilagus sp.*), differing from typical myxoma virus, has been studied extensively under the name fibroma virus. This strain in turn is recognized as consisting of variants and has been investigated as typical (OA) and inflammatory (IA) substrains, antigenically alike but the latter tending to generalize in domestic rabbits. Fibroma virus is not lethal in domestic rabbits as the type strain almost always is; it appears to lack some antigenic constituents, inducing the formation of agglutinins that give cross reactions with the type but of neutralizing and complement-fixing antibodies that do not. The fibroma strain does not generally appear in the blood stream, as myxoma virus does, and is not contagious, at least it does not spread spontaneously among domestic rabbits as the myxoma strain does; the manner of its spread in wild rabbits in nature is not known. Its particle size has been calculated as 126 to 141 millimicrons by centrifugation, 125 to 175 millimicrons by filtration. (Ahlström, Jour. Path. and Bact., *46*, 1938, 461–472; Andrewes, Jour. Exp. Med., *63*, 1936, 157–172; Hoffstadt and Pilcher, Jour. Inf. Dis., *68*, 1941, 67–72; Hurst, Brit. Jour. Exp. Path., *18*, 1937, 1–30; Austral. Jour. Exp. Biol. and Med. FAMILY III. ERRONACEAE *FAM. NOV.*

Viruses of the Encephalitis Group, inducing diseases mainly characterized by effects on nerve tissues.

Key to the genera of family **Erronaceae.**

I. Viruses of the Typical Encephalitis Group.
   Genus I. *Erro*, p. 1248.
II. Viruses of the Poliomyelitis Group
   Genus II. *Legio*, p. 1257.
III. Viruses of the Rabies Group.
   Genus III. *Formido*, p. 1263.

Genus I. **Erro** *gen. nov.*

Viruses of the Typical Encephalitis Group, inducing diseases mainly characterized by injuries to cells of the brain. Vectors of some known to be ticks; dipterous insects may also transmit. Generic name from Latin *erro*, a vagrant.

The type species is *Erro scoticus spec. nov.*

Key to the species of genus **Erro.**

I. Affecting sheep principally, but also man.
   1. *Erro scoticus.*
II. Affecting man principally.
   2. *Erro silvestris.*
   3. *Erro incognitus.*
   4. *Erro japonicus.*
   5. *Erro nili.*
   6. *Erro scelestus.*
III. Affecting horse principally, but also man.
   7. *Erro equinus.*
IV. Affecting horse, cow, sheep.
   8. *Erro bornensis.*

1. **Erro scoticus** *spec. nov.* From Latin *Scoticus*, Scottish.

Common name: Louping-ill virus.

Hosts: *BOVIDAE—Ovis aries* L., sheep. *HOMINIDAE—Homo sapiens* L., man. Experimentally, also mouse, rat (subclinical infection), chick embryo (discrete primary lesions on chorioallantoic membrane), *Macacus rhesus*, horse, cow, pig.

Insusceptible species: Guinea pig, rabbit.

Geographical distribution: Scotland, northern England.

Induced disease: In sheep, encephalitis characterized by dullness followed by incoordination of movement, frequently with tremors chiefly of the head; salivation, champing of jaws; prostration, coma, death. In man, encephalitis with prompt and complete recovery accompanied by formation of specific neutralizing antibodies. In mouse, experimentally, diffuse encephalomyelitis with mild meningeal involvement; following intracerebral inoculation, fine rhythmical tremor involving neck, nose, and ears, unsteadiness, muscle spasms, respiratory distress, sometimes clonic and rarely tonic convulsions; hind limb paralysis, dribbling of urine, cessation of spontaneous limb movements, death; in mouse inoculated intraperitoneally, virus usually enters central nervous system by way of the olfactory mucosa and olfactory bulb, occasionally by trauma at points of

damage; in mouse inoculated intranasally, virus enters blood and reaches the olfactory bulb where it multiplies to a high concentration before infecting the remainder of the brain and the rest of the nervous system; tends to disappear from the blood after sickness begins but persists in the brain until death from encephalitis. In chick embryo, after inoculation of chorioallantoic membrane, edema and opacity spreading from site of inoculation on membrane of 10-day embryo; in 12-day eggs, discrete primary lesions, sometimes with secondary lesions surrounding them on the inoculated membrane; embryo dies in about 6 days, after showing jaundice, edema, mottling of the liver with necrosis; virus regularly in blood. In monkey, *Macacus rhesus*, progressive cerebellar ataxia; encephalomyelitis with involvement and massive destruction of Purkinje cells in the cerebellum.

Transmission: By ticks, *Rhipicephalus appendiculatus* and *Ixodes ricinus* (*IXODIDAE*). In *Rhipicephalus appendiculatus*, the larva or nymph becomes infected; only a few individuals retain virus until the adult stage; virus does not pass through the egg. Non-viruliferous ticks do not acquire virus by feeding with infective ticks on immune animals. Experimentally, by intracerebral or intraperitoneal injection in mouse; by intranasal instillation in rat, mouse, and monkey.

Serological relationships: Complement fixation and neutralization tests show cross reactions with Russian spring-summer encephalitis virus, but immune serum against louping-ill virus is only partially effective in neutralizing the spring-summer encephalitis virus.

Immunological relationships: Mice are protected against louping-ill virus by vaccination with non-virulent spring-summer encephalitis virus but protection is less effective than for the homologous virus. No cross immunity with respect to Rift Valley fever virus or poliomyelitis virus in *Macacus rhesus*, but immunity with respect to reinfection by louping-ill virus has been demonstrated.

Thermal inactivation: At 58° C in 10 minutes.

Filterability: Passes Berkefeld V, N, and W filters.

Other properties: Viable in broth filtrates after storage at 4° C and pH 7.6 to 8.5 for 70 days. Particle diameter, calculated from ultrafiltration data, 15 to 20 millimicrons.

Literature: Alexander and Neitz, Vet. Jour., *89*, 1933, 320–323; Onderstepoort Jour. Vet. Sci. and Anim. Industr., *5*, 1935, 15–33; Alston and Gibson, Brit. Jour. Exp. Path., *12*, 1931, 82–88; Burnet, Jour. Path. and Bact., *42*, 1936, 213–225; Brit. Jour. Exp. Path., *17*, 1936, 294–301; Burnet and Lush, Austral. Jour. Exp. Biol. and Med. Sci., *16*, 1938, 233–240; Casals and Webster, Science, *97*, 1943, 246–248; Jour. Exp. Med., *79*, 1944, 45–63; Elford and Galloway, Jour. Path. and Bact., *37*, 1933, 381–392; Findlay, Brit. Jour. Exp. Path., *13*, 1932, 230–236; Fite and Webster, Proc. Soc. Exp. Biol. and Med., *31*, 1934, 695–696; Galloway and Perdrau, Jour. Hyg., *35*, 1935, 339–346; Hurst, Jour. Comp. Path. and Therap., *44*, 1931, 231–245; M'Fadyean, Jour. Comp. Path. and Therap., 7, 1894, 207–219; *13*, 1900, 145–154; Pool et al., *ibid.*, *43*, 1930, 253–290; Rivers and Schwentker, Jour. Exp. Med., *59*, 1934, 669–685; Schwentker et al., *ibid.*, *57*, 1933, 955–965.

2. **Erro silvestris** *spec. nov.* From Latin *silvestris*, of the forest, in reference to incidence of the induced disease almost exclusively in those who enter forest lands.

Common names: Spring-summer encephalitis virus, forest spring encephalitis virus.

Hosts: Man; probably cattle, horse; *Eutamias asiaticus orientalis*, *Evotomys rufocanus arsenjevi*. Experimentally, also white mouse, *Macacus rhesus*, birds, goat, sheep, *Microtus michnoi pelliceus* Thom., *Cricetulus furunculus*.

Geographical distribution: Union of Soviet Socialist Republics.

Induced disease: In man, acute non-suppurative encephalitis, abrupt onset, steep rise of temperature to 38 to 40° C, severe headache, giddiness, and vomiting; pareses and paralyses of upper or lower limbs or muscles of neck and back; residual atrophic paralyses common; mortality among cases, 30 per cent; 80 per cent of all cases occur in May and June.

Transmission: By tick, *Ixodes persulcatus* (*IXODIDAE*); the virus seems to hibernate in this species and has proved capable of passing through eggs to progeny. Experimentally, also by ticks *Dermacentor silvarum* and *Haemaphysalis concinna* (*IXODIDAE*).

Serological relationships: Virus-neutralizing antibodies, found without other evidence of disease in some men and in many cattle and horses, believed to indicate susceptibility of these hosts to latent infections. No cross neutralization with St. Louis encephalitis virus. Japanese summer encephalitis virus is in part antigenically related, but some antigenic constituents of this virus are missing in spring-summer encephalitis virus and *vice versa*.

Immunological relationships: Formolized virus immunizes specifically.

Filterability: Passes Berkefeld and Chamberland filter candles.

Literature: Smorodintseff, Arch. f. gesamt. Virusforsch., *1*, 1940, 468–480; Soloviev, Acta Med. U. R. S. S., *1*, 1938, 484–492 (Biol. Abst., *17*, 1943, 1726, no. 18777).

3. **Erro incognitus** *spec. nov.* From Latin *incognitus*, unknown, in reference to mystery surrounding the nature and relationships of this virus, as evidenced by common name.

Common name: Australian X-disease virus.

Hosts: *HOMINIDAE—Homo sapiens* L., man. Experimentally, also sheep, horse, cow, rhesus monkey.

Geographical distribution: Australia.

Induced disease: In man, polioencephalitis, especially in children, occurring in late summer; mortality high; characterized by headache, body pains, drowsiness, weakness, then vomiting, fever, convulsions; paralysis of limbs, eye-muscles, or face rare; recovery rapid in non-fatal cases.

Literature: Kneebone, Austral. Jour. Exp. Biol. and Med. Sci., *3*, 1926, 119–127; Perdrau, Jour. Path. and Bact., *42*, 1936, 59–65.

4. **Erro japonicus** *spec. nov.* From New Latin *Japonia*, Japan.

Common name: Japanese B encephalitis virus.

Hosts: *HOMINIDAE—Homo sapiens* L., man. Experimentally, also young sheep, mouse, and *Macacus rhesus*.

Geographical distribution: Japan, Union of Soviet Socialist Republics.

Induced disease: In man, loss of appetite, drowsiness, nausea, then rapid rise of temperature, pains in joints and chest; restlessness followed by apathy, coma; death, usually before end of second week, or recovery, sometimes with persistence of evidences of damage done to the nervous system by the disease.

Serological relationships: Specific antiserum does not neutralize St. Louis encephalitis virus or louping-ill virus. Russian autumn-encephalitis virus induces the formation of antisera neutralizing Japanese B encephalitis virus. Russian spring-summer encephalitis virus contains some, but not all, antigens in common with this virus. Australian X-disease virus is distinct in neutralization tests.

Immunological relationships: Specific immunity as a result of earlier infection in mice; no cross protection with respect to St. Louis encephalitis virus. Vaccination with Japanese B encephalitis virus does not enhance resistance to West Nile encephalitis virus but only to the homologous virus.

Thermal inactivation: At 56° C in 30 minutes.

Filterability: Passes Berkefeld N, W, Chamberland L_2, L_3, and Seitz EK filters, with ease.

Literature: Kudo et al., Jour. Immunol., *32*, 1937, 129–135; Smorodintseff et al., Arch. f. gesamt. Virusforsch., *1*, 1940, 550–559; Webster, Jour. Exp. Med., *67*, 1938, 609–618.

5. **Erro nili** *spec. nov.* From Latin *Nilus*, god of the Nile.

Common name: West Nile encephalitis virus.

Hosts: *HOMINIDAE—Homo sapiens* L., man (perhaps without inducing any definite disease). Experimentally, also rhesus monkey, mouse.

Geographical distribution: Africa (Uganda).

Induced disease: In man, no details are known; virus was originally isolated from blood of a woman native of Uganda; at the time the temperature of the patient was 100.6° F but she denied illness; moreover, two laboratory workers developed neutralizing antibodies without recognizable clinical disease. In mouse, experimentally, after intracerebral inoculation, incubation period to 4 or 5 days, then hyperactivity and roughening of coat; later, weakness, hunched attitude, sometimes paralysis of hind quarters; usually coma before death. In rhesus monkey, experimentally, after intracerebral or intranasal inoculation, fever and encephalitis.

Serological relationships: No cross reactions in complement fixation tests between this and equine encephalitis virus, Japanese B encephalitis virus, St. Louis encephalitis virus, or lymphocytic choriomeningitis virus. Neutralization tests show some common antigens in West Nile encephalitis virus, Japanese B encephalitis virus and St. Louis encephalitis virus; antiserum to West Nile virus does not neutralize either of the others but antisera against St. Louis virus may neutralize West Nile virus and antisera against Japanese B virus have some effectiveness in neutralizing both West Nile virus and St. Louis virus.

Immunolcgical relationships: Vaccination with this virus dces not enhance resistance to Japanese B or St. Louis encephalitis viruses but only resistance to the homolcgous virus.

Thermal inactivation: At 55° C, not at 50° C, in 30 minutes.

Filterability: Passes Berkefeld V, N, and W filter candles readily; also passes Seitz EK asbestos pads and collodion membranes 79, not 62, millimicrons in average pore diameter.

Other properties: Infective particle 21 to 31 millimicrons in diameter, as calculated from filtration experiments. Viable at least 2 weeks at 2 to 4° C. Viable after drying from the frozen state.

Literature: Havens et al., Jour. Exp. Med., *77*, 1943, 139–153; Smithburn, Jour. Immunol., *44*, 1942, 25–31; Smithburn et al., Am. Jour. Trop. Med., *20*, 1940, 471–492.

6. **Erro scelestus** *spec. nov.* From Latin *scelestus*, infamous.

Common name: St. Louis encephalitis virus.

Hosts: *HOMINIDAE—Homo sapiens* L., man. A great number of mammals and birds in endemic areas may have antisera that neutralize the virus, indicating that they are probably natural hosts; among these are: *ANATIDAE—Anas platyrhyncha* L., Mallard and Pekin ducks; *Anser anser* (L.), domestic goose. *BOVIDAE—Bos taurus* L., cow; *Capra hircus* L., goat; *Ovis aries* L., sheep. *CANIDAE—Canis familiaris* L., dog. *COLUMBIDAE—Columba livia*, domestic pigeon; *Zenaidura macroura*, western mourning dove. *EQUIDAE—Equus caballus* L., horse. *FALCONIDAE—Falco sparverius* L., sparrow hawk. *LEPORIDAE—Lepus californicus* Gray, jack rabbit; *Sylvilagus nuttalli*, cottontail rabbit. *MELEAGRIDAE—Meleagris gallopavo* L., turkey. *MURIDAE—Rattus norvegicus* (Berkenhout), brown

rat. *MUSCICAPIDAE*—*Turdus migratorius* L., robin. *PHASIANIDAE*—*Gallus gallus* (L.), chicken; *Lophortyx californica*, California quail. *PICIDAE*—*Asyndesmus lewis*, Lewis woodpecker; *Colaptes cafer* (Gm.), red-shafted flicker. *STRIGIDAE*—*Bubo virginianus* (Gm.), great horned owl. *SUIDAE*—*Sus scrofa* L., pig. Experimentally, white mouse (some substrains of the Swiss white mouse are genetically more readily infected than others); *Macacus rhesus*; pigeon (inapparent infection); chick embryo and to a limited extent the young hatched chick.

Insusceptible species: Laboratory rabbit, *Cebus* monkey, guinea pig, rat.

Geographical distribution: United States.

Induced disease: In man, during summer and fall, about 9 to 21 days after exposure, headache, high fever, rigidity of neck, tremors; encephalitis, usually with fever; some patients become drowsy, others sleepless or delirious; usual sequelae headaches, irritability, some loss of memory, and drowsiness; neutralizing antibodies maintained *in vivo* at least 2½ years after occurrence of disease. Experimentally, in susceptible strains of white mouse inoculated by intracerebral injection, after 3 to 4 days, coarse tremors, convulsions, prostration, death; perivascular accumulations of mononuclear leucocytes throughout brain, stem, cord, and pia, with destruction of pyramidal cells in the *lobus piriformis* and *cornu Ammonis*; subcutaneous and intraperitoneal injections immunize against subsequent infection by intracerebral inoculation, virus reaching only blood and spleen in the process of immunization unless an excessive dose is given; some substrains of the White Swiss mouse are relatively resistant to infection, requiring inoculation with about 1000 times the minimal infective dose for highly susceptible strains and when infected proving relatively poor sources of virus for subinoculation; highly susceptible substrains of the White Swiss mouse lack a single major, dominant, genetic factor that is present in resistant substrains.

Transmission: By mosquito, *Culex tarsalis* Coquillett (*CULICIDAE*), probably extensively; this insect has been collected in nature carrying the virus. Experimentally, by larvae of American dog tick, *Dermacentor variabilis* (Say) (*IXODIDAE*); by mosquito, *Culex pipiens* Linn., var. *pallans* Coq. (*CULICIDAE*). To mice, by feeding on infected tissues.

Serological relationships: Human antisera may neutralize virus after clinical and subclinical attacks.

Immunological relationships: Specific intracerebral immunity after vaccination by subcutaneous or intraperitoneal injection in mice appears early (about 1 week after vaccination) and disappears before humoral antibody titer reaches its maximum.

Thermal inactivation: At 56° C in 30 minutes.

Filterability: Passes Berkefeld V and N filter candles and collodion membranes 66 millimicrons in average pore diameter.

Other properties: Storage in human brain tissue in glycerine inactivates this virus in about 32 days. Diameter of infective particle calculated from filtration data as about 20 to 33 millimicrons. In storage, rabbit and sheep sera act to some extent as preservatives. At 4° C, after drying *in vacuo* while frozen, viable in apparently undiminished titer for at least 17 months.

7. **Erro equinus** *spec. nov.* From Latin *equinus*, pertaining to horses.

Common name: Equine encephalitis virus.

Hosts: *EQUIDAE—Equus caballus* L., horse; F_1 hybrid of the horse and *E. asinus* L., mule. *HOMINIDAE—Homo sapiens* L., man. *COLUMBIDAE—Columba livia*, domestic pigeon. *PHASIANIDAE*—ring-necked pheasant. *TETRAONIDAE—Tympanuchus cupido* L., var. *americanus* (Reichenbach), prairie chicken. Many additional species have been found to show neutralizing antisera at times and these are presumably natural hosts of the virus upon occasion; among them are: *ANATIDAE—Anas platyrhyncha* L., Mallard and Pekin ducks; *Anser anser* (L.), domestic goose. *BOVIDAE—Bos taurus* L., cow; *Capra hircus* L., goat; *Ovis aries* L., sheep. *CANIDAE—Canis familiaris* L., dog. *CHARADRIIDAE—Oxyechus vociferus* L., killdeer. *CRICETIDAE—Microtus montanus* (Peale), field mouse; *Peromyscus maniculatus* (Wagner), white-footed mouse. *FALCONIDAE—Falco sparverius* L., sparrow hawk. *MELEAGRIDAE—Meleagris gallopavo* L., turkey. *MURIDAE—Rattus rattus* L., black rat. *MUSCICAPIDAE—Turdus migratorius* L., robin. *MUSTELIDAE—Mustela frenata* Lichtenstein, weasel. *PHASIANIDAE—Gallus gallus* (L.), chicken; *Lophortyx californica*, California quail; *Phasianus colchicus* L., ring-necked pheasant. *PICIDAE—Colaptes cafer* (Gm.), red-shafted flicker. *STRIGIDAE—Bubo virginianus* (Gm.), great horned owl. *SUIDAE—Sus scrofa* L., pig. Experimentally, also chick embryo, goose embryo, pheasant embryo, robin embryo, pigeon embryo, turkey embryo, sparrow embryo, duck embryo, and guinea-fowl embryo; white mouse, guinea pig, rabbit, pigeon, white rat, calf, sheep, monkey, goat, dog, hen, turkey; *Zonotrichia leucophrys gambeli*, Gambel sparrow; *Passer domesticus* L., English sparrow; *Lophortyx californica*, quail; *Junco oreganus*, junco; *Toxostoma lecontei lecontei*, thrasher; *Citellus richardsonii* (Sabine), gopher or Richardson's ground squirrel; *Sigmodon hispidus* Say and Ord, cotton rat; *Dipodomys heermanni* Le Conte, kangaroo rat; *Reithrodontomys megalatus*, wild mouse; *Microtus montanus*, *M. californicus* and *M. mordax*, wild mice; *Peromyscus maniculatus* (Wagner), white-footed mouse; *Neotoma fuscipes* Baird, wood rat; *Sylvilagus bachmani* (Waterhouse), brush rabbit; *S. audubonii* (Baird), cottontail rabbit; *Canis familiaris* L., dog (puppies); *Anser cinereus*, goose; *Anas boscas* L., duck; *Circus rufus* (Gm.), hawk; *Turdus merula* L., blackbird; *Ciconia ciconia* L., white stork; *Vultur fulvus* Briss., tawny vulture; *Marmota monax* (L.), woodchuck; *Microtus pennsylvanicus* (Ord.), field vole; *Speotyto cunicularia hypugaea* (Bonaparte), western burrowing owl; *Molothrus ater* (Boddaert), cowbird; common quail or bob-white.

Insusceptible species: Frog (cat and opossum reported as "refractory").

Geographical distribution: United States, Canada, Argentina.

Induced disease: In horse, initial fever, then signs of fatigue, somnolence; occa-

sional excitability followed by incoordinated action of limbs, disturbed equilibrium, grinding of teeth, paresis and varied paralyses; frequently inability to swallow, paralysis of lips and bladder, amaurosis; case fatality about 50 per cent; recovery without sequelae in mild cases; death within 3 to 8 days in severe cases. In man (children particularly vulnerable), a profound, acute, disseminate and focal encephalomyelitis characterized by intense vascular engorgement, perivascular and parenchymatous cellular infiltration and extreme degenerative changes in the nerve cells. In chick embryo, excessive increase of virus continuing until just before host's death, virus being found eventually throughout the egg but most concentrated in the embryo; vaccines made from virus grown in chick embryo and then inactivated are especially effective because of the high titer of virus represented in them; increased resistance with age characteristic of chorioallantoic membrane as well as of hatched chick; rounded acidophilic masses occur usually near periphery of nucleus in embryonic nerve cells; no such inclusions are found as a result of infection with Borna disease virus or poliomyelitis virus.

Transmission: Experimentally by tick, *Dermacentor andersoni* Stiles (*IXODIDAE*), passing through eggs to offspring; this tick is infective to susceptible animals on which it feeds as larva, nymph or adult. Experimentally by *Aëdes aegypti* L. (to guinea pig and horse, preinfective period 4 to 5 days; insects retain virus for duration of life; not to eggs of infected mosquitoes; not passed from males to females or by males from female to female), *A. albopictus*, *A. atropalpus*, *A. cantator*, *A. dorsalis*, *A. nigromaculis*, *A. sollicitans*, *A. taeniorhynchus*, *A. triseriatus*, and *A. vexans* (*CULICIDAE*). *Triatoma sanguisuga* (Le Conte) (*REDUVIIDAE*) has been found infected in nature and has transmitted virus experimentally to guinea pigs. The American dog tick, *Dermacentor variabilis* Say (*IXODIDAE*) has been infected by inoculation, not by feeding; it has not been shown to transmit.

Serological relationships: Neutralizing antibodies are formed as a result of vaccination with inactive, formolized virus; antigenicity of formalin-inactivated virus as well as of active virus is blocked in the presence of antiserum. In rabbit, cerebral resistance is coincident with presence of neutralizing antibody in spinal fluid. In guinea pig, therapy with specific antiserum ineffective if begun after onset of encephalitis; effective if begun within 24 to 48 hours of peripheral inoculation. No cross neutralization reaction with lymphocytic choriomeningitis virus, Japanese B encephalitis virus or St. Louis encephalitis virus. Constituent strains (typical Western and Eastern) do not give cross neutralization reactions, but do show the presence of common antigens by cross reactions in complement fixation not shared with such other viruses as Japanese B encephalitis virus, St. Louis encephalitis virus, West Nile encephalitis virus, lymphocytic choriomeningitis virus. Sera of human cases may be negative by complement fixation tests a few days after onset, yet strongly strain-specific during second week of illness.

Immunological relationships: Young of immunized guinea pigs are immune to homologous strain at least a month after birth. No cross immunity between Western and Eastern strains of equine encephalitis virus.

Thermal inactivation: At 60° C, not at 56° C, in 10 minutes.

Filterability: Passes collodion membranes 66, not 60, millimicrons in average pore diameter. Passes Berkefeld V, N, and W, finest Mandler, and Seitz filters.

Other properties: Inactivated below pH 5.5. Viable at least a year, dry in vacuum. Particle diameter estimated from filtration experiments to be 20 to 30 millimicrons. Electron micrographs show particles as spherical or disk-shaped, about 39 millimicrons in diameter with round or oval region of high density within each; older preparations show

comma-shaped particles. Sedimentation constant, mean $265.5 \times 10^{-13} \pm 5.4 \times 10^{-13}$ (range 252 to 276×10^{-13}). Specific volume 0.864. Molecular weight of liponucleoprotein complex behaving as the virus calculated as 152 million, approximately 250 particles giving 50 per cent infection; material contains 4 per cent carbohydrate. Absorption of ultraviolet light reaches a peak at about 2600 Å., a broad minimum at about 2450 Å., and an increase at 2200 Å.

Strains: The Western strain (so-called Western equine encephalitis virus) may be considered as type of a large group of variants met in nature; some produce clinically milder disease than others (Birch, Am. Jour. Vet. Res., *2*, 1941, 221–226); they may change in virulence on passage in experimental hosts. The Eastern strain (so-called Eastern equine encephalitis virus) has been studied extensively also, and has been found to differ from the type strain especially: in more rapid course of induced disease in the horse; in being experimentally transmissible to sheep, pig, dog, cat and the European hedgehog; in its localization in eastern coast states and absence from the area between California and Wisconsin, where the type strain is found; in failure experimentally to infect *Aëdes aegypti* unless inoculated into body cavity by needle puncture, whereupon it persists and can be transmitted; and in failure of cross-neutralization with the western strain. A strain produced by serial passage in pigeons is reported to have caused no obvious reaction in horses but to have induced the formation of neutralizing antibodies. A Venezuelan strain differs from the type in complement-fixation reactions; it induces in man a mild disease, characterized by malaise, fever, headache or drowsiness, and uneventful recovery (Casals et al., Jour. Exp. Med., *77*, 1943, 521–530).

8. **Erro bornensis** *spec. nov.* From Borna, name of a town in Saxony where a severe epizootic occurred in 1894 to 1896.

Common name: Borna-disease virus.

Hosts: Horse, cow, sheep, perhaps deer. Experimentally, also rabbit, guinea pig, rat (more susceptible when old than when younger), mouse; *Macaca mulatta* (Zimmermann) rhesus monkey.

Insusceptible species: Ferret, cat, pigeon; probably dog.

Geographical distribution: Würtemburg, Germany, North and South America, Hungary, Russia, Belgium, France, Italy, Roumania.

Induced disease: In horse, encephalomyelitis characterized by lassitude, indifference to external stimuli; later intermittent excitement, difficulty in mastication and deglutition, spasms in various muscles, champing, excessive salivation; pupils unequal in size; paralysis of hindquarters, tail, muscles of tongue, or muscles of back; temperature usually normal; death in 20 to 37 hours or, less often, recovery after about 1 to 3 weeks. Virus may pass placenta and infect fetus in pregnant animals.

Transmission: To rabbit, experimentally by feeding and by injection intracerebrally, intraocularly, nasally, intravenously, subcutaneously, or intraperitoneally; not by living in same cage.

Immunological relationships: No cross immunity conferred by the Western strain of equine encephalomyelitis virus. Isolate of Borna disease virus from the horse immunizes rabbits against isolate from sheep, and *vice versa*. Herpes and rabies viruses do not immunize rabbits against subsequent infection by Borna disease virus.

Thermal inactivation: At 50 to 57° C in 30 minutes; at 70° C in 10 minutes.

Filterability: Passes Berkefeld N and Mandler filters, but with difficulty. Passes collodion membranes of average pore diameter 400 millimicrons readily, 200 millimicrons with difficulty, 175 millimicrons not detectibly. May be separated by differential filtration from louping-ill virus, which will pass even a 125-millimicron membrane.

Other properties: Particle size estimated from filtration data as 85 to 125 millimicrons. Optimum pH for stability in broth at 15 to 20° C is 7.4 to 7.6; very sensitive to greater alkalinity Viable after 327 days dry at laboratory temperatures. Viable at least 6 months in 50 per cent glycerine. Inactivated by putrefaction in 5 days; by 1 per cent carbolic acid in 4, not in 2, weeks.

Literature: Barnard, Brit. Jour. Exp. Path., *14*, 1933, 205–206; Covell, Proc. Soc. Exp. Biol. and Med., *32*, 1934, 51–53; Elford and Galloway, Brit. Jour. Exp. Path., *14*, 1933, 196–205; Howitt and Meyer, Jour. Infect. Dis., *54*, 1934, 364–367; Nicolau and Galloway, Brit. Jour. Exp. Path., *8*, 1927, 336–341, and in Medical Research Council, Special Report Series No. 121, London, 1928, 90 pp., Ann. Inst. Pasteur, *44*, 1930, 673–696; *45*, 1930, 457–523; Zwick et al., Ztschr. Infektionskr. parasit. Krankh. u. Hyg. d. Haustiere, *30*, 1926, 42–136; *32*, 1927, 150–179.

Genus II. **Legio** *gen. nov.*

Viruses of the Poliomyelitis Group, often recoverable from feces of infected hosts, probably because of involvement of some part of the alimentary tract; usually there is also obvious involvement of some part of the nervous system. Generic name from Latin *legio*, an army or legion.

The type species is *Legio debilitans spec. nov.*

Key to the species of genus **Legio.**

I. Affecting man (see also IV below).
  1. *Legio debilitans.*
  2. *Legio crebea.*
  3. *Legio simulans.*

II. Latent in, or affecting, mouse.
  4. *Legio muris.*

III. Affecting birds.
  5. *Legio gallinae.*

IV. Affecting swine and swineherds.
  6. *Legio suariorum.*

1. **Legio debilitans** *spec. nov.* From Latin *debilitare*, to weaken or maim.

Common names: Poliomyelitis virus, virus of infantile paralysis.

Hosts: *HOMINIDAE—Homo sapiens* L., man. Experimentally, *Cercopithecus aethiops sabaeus*, green African monkey; *Macaca mordax*; *M. mulatta*, the rhesus monkey; *M. irus*, the cynomolgus monkey; mona monkey; for some isolates, *Sigmodon hispidus* Say and Ord, cotton rat; mouse; guinea pig; white rat.

Insusceptible species: Sheep ("refractory" but forms neutralizing antibodies), chicken.

Geographical distribution: Almost world-wide.

Induced disease: In man, probably subclinical in most cases, in view of the presence of specific antibodies in sera from the great majority of adults in all parts of the world; virus probably infects some part of the alimentary tract, being found in stools of most clinical cases, of most apparently healthy contacts, and even of some individuals who have recovered from abortive attacks (in one case 123 days after attack); clinical disease, largely in children, is characterized by invasion of central nervous system, with effects ranging from sore throat, fever, vomiting, and headache to sudden and severe paralysis; the muscles most often involved are those of the legs, but there may be paralysis of abdominal or intercostal muscles. Virus not in urine or saliva, rarely in nasal washings; more often in stools of young than of old patients; in walls of pharynx, ileum, descending colon. Virus has been recovered from sewage. Incidence and fatality affected by racial characteristics, the first lower and the second higher in negroes than in whites in the United States. In monkey, similar disease, no virus in blood, relapse with reappearance of virus reported; in isolated intestinal loops, infection does not occur through normal mucosa in absence of intestinal contents; disease more severe in summer than in autumn, in autumn than in winter; more severe in older than in younger monkeys; no immunity follows inoculation unless obvious disease occurs.

Transmission: Transmission in milk has been suspected and at times confirmed. Virus has been recovered from mixed samples of flies in an epidemic area. No definite arthropod vector has been incriminated. Experimentally, in *Cercopithecus aethiops sabaeus*, the green

African monkey, by intracerebral, intranasal, and intraabdominal inoculation.

Serological relationships: Specific neutralizing antibodies arise after experimental infection in monkeys, but reinfection is not prevented; only a minority of human convalescent sera neutralize virus *in vitro*, the most potent sera probably being obtained from those with transient or light paralysis. Cross neutralization between monkey-passage and murine (cotton-rat and mouse) strains. No cross-neutralization reaction with lymphocytic choriomeningitis virus. Isolates differ somewhat antigenically, homologous titers being higher than heterologous titers in some neutralization tests.

Thermal inactivation: At or below 75° C in 30 minutes.

Filterability: Passes membrane about 35, not 30, millimicrons in average pore diameter.

Other properties: Infectivity of virus maintained well at −76° C or in glycerine but poorly when dried or just frozen. Inactivated readily by hydrogen peroxide. Particle diameter estimated as about 12 millimicrons by filtration studies. Precipitated by half-saturated ammonium sulphate solutions. Electron micrographs show elliptical particles 20 to 30 millimicrons in diameter; impure infectious materials show long threads 20 by 75 to 500 millimicrons in size. Component probably virus has sedimentation constant $S_{20°} = 62 \times 10^{-13}$ cm per sec. per dyne. Inactivated by potassium hydroxide, copper sulfate and potassium permanganate. Stable from pH 2.2 to 10.4 for 2 hours at 37° C.

2. Legio erebea *spec. nov.* From Latin *erebeus*, belonging to the Lower World.

Common names: Choriomeningitis virus, lymphocytic choriomeningitis virus.

Hosts: *MURIDAE—Mus musculus* L., gray or white mouse. *HOMINIDAE—Homo sapiens* L., man. *CERCOPITHECIDAE—Macaca mulatta*, rhesus monkey. Experimentally, also guinea pig; white rat; dog (masked); ferret (masked); *Macaca irus*, crab-eating macaque; Syrian hamster; chick- or mouse-embryo serum-Tyrode solution culture; chick embryo.

Insusceptible species: Pig, rabbit, field vole, bank vole, canary, hen, parakeet.

Geographical distribution: France, England, United States.

Induced disease: In white mouse, more virulent in young than in old individuals; infection may take place *in utero* or soon after birth; some mice become carriers after recovery, with virus in organs, blood, urine, and nasal secretions; carriers are immune to large intracerebral inoculations of virus; experimentally, 5 to 12 days after intracerebral inoculation of susceptible mice, somnolence, photophobia, tremors of the legs, tonic spasms of muscles in the hindquarters upon stimulation; recovery or death. In man, disease may be subclinical at times as shown by the fact that some supposedly normal sera contain specific antibodies; not all clinical cases develop protecting antibodies against testing strains, so that disease may be somewhat commoner than can be ascertained readily; in all cases benign, but in the more severe of these an acute aseptic meningitis; after incubation period of 1½ to 3 days, spells of fever extending as long as 3 weeks; late in the disease there may be a meningeal reaction both clinically and cytologically; lymphocytes and some large mononuclear cells appear in the meningeal fluids, although symptoms remain benign; there may be virus in the blood from the beginning of fever to the end of the second week; the spinal fluid is not infective at first but may become so before there is a change in cell count; urine and saliva remain uninfectious.

Transmission: In white mouse, by contact with mice infected when young, not with those infected when old; nasal mucosa considered portal of entry. In wild gray mouse of the same species, *Mus musculus*, by contact but less readily than in white mouse. Experimentally, by mosquito, *Aëdes aegypti* L. (*CULICIDAE*), at 26 to 34° C; by bedbug, *Cimex lectularius* (*CIMIDAE*), but defecation on site of bitten area is essential, bite alone being ineffective. Experimentally, to guinea pig, by application of virus to normal and apparently intact skin; not by contamination of food or litter.

Serological relationships: Serum of recovered subjects usually neutralizes choriomeningitis virus. Hyperimmune serum is ineffective against pseudo-lymphocytic choriomeningitis virus and hyperimmune serum for that virus is ineffective in its turn when used with choriomeningitis virus. No cross neutralization with St. Louis encephalitis virus. A specific soluble antigen associated quantitatively with virus in all hosts fixes complement in the presence of immune serum; virus does so poorly if at all; the anti-soluble-substance antibodies seem to be independent of virus-neutralizing antibodies. A soluble protein, readily separable from virus, gives a specific precipitin reaction with immune serum; antibodies concerned are probably not the virus-neutralizing antibodies.

Immunological relationships: Intraperitoneal injection of about 160 intracerebral lethal doses has been found to protect the white mouse against infection by subsequent intracerebral injection of 10,000 lethal doses. The immune mouse differs from the immune guinea pig in showing no neutralizing antibodies in its blood; even the guinea pig may develop resistance before antibodies appear in its serum. Formalized vaccines made from

guinea pig tissues immunize the guinea pig but vaccines made from mouse tissues do not. Mice immune to this virus are susceptible to infection with pseudo-lymphocytic choriomeningitis virus and *vice versa*.

Thermal inactivation: At 55 to 56° C in 20 minutes.

Filterability: Passes Berkefeld V, N, and W filters and, with difficulty, a Seitz asbestos pad.

Other properties: Infective at least 206 days in storage at 4 to 10° C in 50 per cent neutral glycerine in 0.85 per cent saline. Infective particle calculated to be 37 to 55 millimicrons in diameter on the basis of centrifugation studies; 40 to 60 millimicrons by ultrafiltration tests. Inactivated by soap with loss of mouse-immunizing capacity.

3. **Legio simulans** *spec. nov.* From Latin *simulare*, to imitate, in reference to resemblance of this virus to the preceding in many respects, though not in size or antigenic properties.

Common name: Pseudo-lymphocytic choriomeningitis virus.

Hosts: *HOMINIDAE—Homo sapiens* L., man. Experimentally, also mouse, guinea pig, rhesus monkey; chorioallantoic membrane of chick embryo.

Induced disease: In man, benign aseptic lymphocytic meningitis with virus in cerebro-spinal fluid; severe frontal headache, drowsiness, irritability, vomiting, eventual complete recovery. In mouse, experimentally, roughened fur, spontaneous tremor, hunched attitude, irritability, clonic movements ending with tonic convulsions on stimulation, temporary recovery from spasm with survival a few hours or instant death.

Serological relationships: Hyperimmune sera for lymphocytic choriomeningitis virus are ineffective for this virus, and *vice versa*. In man, after recovery, neutralizing antibody is strong at 1 month, fading before 7 months.

Immunological relationships: Mice acquire specific resistance to reinfection after experimental disease; mice immune to lymphocytic choriomeningitis virus are susceptible to pseudo-lymphocytic choriomeningitis virus and *vice versa*.

Thermal inactivation: At 56° C, not at 45° C, in 30 minutes.

Filterability: Passes Berkefeld V, not N, filter candle; Gradacol membrane of 320, not 300, millimicron average pore diameter.

Other properties: Particle diameter calculated to be not above 150 to 225 millimicrons, from filtration experiments.

Viable at least 1 month at 4° C, at least 1 year in 50 per cent glycerine, 40 days in 0.25 per cent phenol, 1 year when dried from frozen material. Inactivated by 0.05 per cent formalin at 4° C in 48 hours; by boiling in 5 minutes.

Literature: MacCallum et al., Brit. Jour. Exp. Path., *20*, 1939, 260–269.

4. **Legio muris** *spec. nov.* From Latin *mus*, mouse.

Common names: Mouse-poliomyelitis virus, Theiler's-disease virus.

Host: *MURIDAE—Mus musculus* L., white mouse.

Insusceptible species: *CERCOPITHECIDAE—Macaca mulatta* (Zimmermann), rhesus monkey.

Geographical distribution: United States, Japan, Germany, Palestine; probably widespread wherever white mice are raised.

Induced disease: In white mouse, ordinarily no obvious disease, virus occurring in feces and not being recoverable from thoracic or abdominal viscera or head (probable source is in abdominal wall; virus has been recovered most abundantly from intestinal contents, in moderate amounts from walls of intestine and in smaller concentration from mesenteric lymph glands); occasionally, individual mice show flaccid paralysis of hind legs, and brain or spinal-cord suspensions from these contain the virus; mice inoculated intracerebrally show flaccid paralysis in 7 to more than 30 days, first in one limb, later usually in all; the tail does not become paralyzed; very young inoculated mice may die without first showing paralysis; very old inoculated mice may become infected without showing obvious disease; some affected mice recover and those showing residual paralysis may become carriers of virus. In affected, experimentally inoculated mice, acute necrosis of ganglion cells of anterior horn of spinal cord; necrosis also of isolated ganglion cells of cerebrum. Later, marked neuronophagia. Perivascular infiltration in brain and spinal cord. The reciprocal of the incubation period has been found approximately proportional to the logarithm of the amount of virus inoculated, thus serving to measure the concentration of samples of virus. Old mice less susceptible than young.

Transmission: Experimentally, by intracerebral, intranasal and intraperitoneal inoculation. Has been found to persist in adult flies, *Musca domestica* L. (*MUSCIDAE*) and other species, as long as 12 days after experimental feeding whereas mouse-adapted human poliomyelitis virus persists only 2 days in *Musca domestica* and not at all in some other species.

Serological relationships: Sera containing antibodies to the Lansing strain of human poliomyelitis virus fail to protect against mouse poliomyelitis virus.

Immunological relationships: Recovered mice are immune to various heterologous isolates or strains. No evidence of immunological relationship with virus of human poliomyelitis has been obtained, save that mice paralyzed with mouse poliomyelitis virus show some resistance to infection with the Lansing strain of human poliomyelitis virus; this has been interpreted as possibly no more than an interference phenomenon, since it seems to depend on actual paralysis.

Filterability: Passes Berkefeld N and other Berkefeld filters and Chamberland L_3 filter.

Other properties: Viable at least 14 months at −78° C; at least 150 days in 50 per cent glycerine at 2 to 4° C. Most stable near pH 8.0 and pH 3.3. Inactivated readily at 37° C by 1 per cent hydrogen peroxide. Particle diameter estimated as 9 to 13 millimicrons from filtration studies. Sedimentation constant, $S_{20°} = 160$ to 170×10^{-13} cm per sec. per dyne.

Literature: Bang and Glaser, Am. Jour. Hyg., *37*, 1943, 320-324; Gahagan and Stevenson, Jour. Inf. Dis., *69*, 1941, 232–237; Gard, Jour. Exp. Med., *72*, 1940, 69–77; Gard and Pedersen, Science, *94*, 1941, 493–494; Gildemeister and Ahlfeld,

Cent. f. Bakt., I Abt., Orig., *142*, 1938, 144–148; Iguchi, Kitasato Arch. Exp. Med., *16*, 1939, 56–78; Olitsky, Jour. Exp. Med., *72*, 1940, 113–127; Theiler, Science, *80*, 1934, 122; Jour. Exp. Med., *65*, 1937, 705–719; Theiler and Gard, *ibid.*, *72*, 1940, 49–67, 79–90; Young and Cumberland, Am. Jour. Hyg., *37*, 1943, 216–224.

5. **Legio gallinae** *spec. nov.* From Latin *gallina*, hen.

Common names: Avian encephalomyelitis virus, infectious avian encephalomyelitis virus.

Host: *PHASIANIDAE—Gallus gallus* (L.), chicken (embryo not susceptible; in culture media, minced whole embryo in serum-Tyrode solution suffices to maintain virus, but embryo brain alone does not).

Insusceptible species: All tested species other than birds.

Geographical distribution: United States.

Induced disease: In chicken, fine or coarse tremors of whole body or only of head and neck or of legs; progressive ataxia; eyes dull, some loss of weight, weakness of legs, and progressive incoordination of leg muscles; somnolence precedes death; about 75 per cent die within 5 days of onset, 90 per cent within a week, the remainder showing a staggering, ataxic gait for weeks, some continuously tremulous; recovered birds, however, may produce eggs well; microscopic focal collections of glia cells, perivascular infiltration, degeneration of Purkinje's cells and degeneration of nerve cells; foci of infiltration throughout brain and spinal cord; virus not detected in the blood of affected chickens.

Transmission: Not through egg. Experimentally, by intracerebral injection.

Serological relationships: Specific antiserum neutralizes homologous virus but not the Eastern strain of equine encephalitis virus; antiserum specific for the latter does not neutralize avian encephalomyelitis virus.

Filterability: Passes Berkefeld V and N as well as Seitz 1 and 2 filters; also membranes 73 millimicrons in average pore diameter.

Other properties: Survives in 50 per cent glycerine for at least 88 days and frozen for at least 68 days. Infective particle estimated to be 20 to 30 millimicrons in diameter, by filtration studies.

Literature: Jones, Science, *76*, 1932, 331–332; Jour. Exp. Med., *59*, 1934, 781–798; Kligler and Olitsky, Proc. Soc. Exp. Biol. and Med., *43*, 1940, 680–683; Olitsky, Jour. Exp. Med., *70*, 1939, 565–582; Olitsky and Bauer, Proc. Soc. Exp. Biol. and Med., *42*, 1939, 634–636; Van Roekel et al., Jour. Am. Vet. Med. Assoc., *93* (N.S. *46*), 1938, 372–375.

6. **Legio suariorum** *spec. nov.* From Latin *suarius*, swineherd.

Common name: Swineherds'-disease virus.

Hosts: *SUIDAE—Sus scrofa* L., swine. *HOMINIDAE—Homo sapiens* L., man. Experimentally, with fever as only symptom, white rat, cat, ferret, mouse; perhaps *Macaca mulatta* (Zimmermann), rhesus monkey.

Geographical distribution: Europe.

Induced disease: In man, a benign meningitis without sequelae, somewhat similar to lymphocytic choriomeningitis in man; cell counts in spinal fluids may be as high as 1200 to 1400; 4 to 7 (average 8) days after infection, fever lasting 3 to 21 days (average 9); sometimes conjunctivitis, more often a reddish maculopapillose eruption; severe sweating frequent; hemorrhagic tendency; blood in feces; recovery. Blood, urine, feces infectious, not spinal fluid or mucous excretions. Especially affecting young men, not often old men or women, among those having contact with swine or swine-producing quarters.

Transmission: Excreta of pigs, even as used for manure, are infective. Experimentally, to man, by subdermal or intramuscular injection.

Serological relationships: Serum from recovered cases neutralizes the virus.

Immunological relationships: Specific immunity follows attack of the disease.

Filterability: Passes Chamberland L_2 filter.

Literature: Durand et al., Compt. rend. Acad. Sci., Paris, *203*, 1936, 830–832, 957–959, 1032–1034; Arch. Inst. Pasteur de Tunis, *26*, 1937, 213–227; 228–249; *27*, 1938, 7–17.

Genus III. **Formido** *gen. nov.*

Viruses of the Rabies Group, inducing diseases characterized by involvement of the nervous system only. Generic name from Latin *formido*, a frightful thing.

The type and only recognized species is *Formido inexorabilis spec. nov.*

1. **Formido inexorabilis** *spec. nov.* From Latin *inexorabilis*, implacable.

Common name: Rabies virus.

Hosts: *CANIDAE—Canis familiaris* L., dog. *FELIDAE—Felis catus* L., domestic cat; *F. negripes*, black-footed cat; *F. ocreata*, wild cat. *HOMINIDAE—Homo sapiens* L., man. *MUSTELIDAE—Ictonyx orangiae*, polecat. *SCIURIDAE—Geosciurus capensis*, ground squirrel. *VIVERRIDAE—Cynictis penicillata*, yellow mongoose (yellow meercat); *Genetta felina* (Thunb.), genet cat; *Myonax pulverulentus*, small, grey mongoose; *Suricata suricatta*, Cape suricate or common meercat. Cattle, sheep, pig, horse, wolf. *Cynalopex chama*, silver jackal. *Phyllostoma superciliatum*, vampire bat; *Desmodus rufus*, vampire bat; *Artibeus planirostris trinitatis*, fruit-eating bat. Experimentally, also *Mus musculus* L., white mouse; *Peromyscus polionotus polionotus* (Wagner), white-footed mouse; tissue cultures of 5 or 6-day-old rat- or mouse-embryo brain; chick embryo (allantois not regularly infected, but virus regularly reaches brain of embryo without injuring it; chick may hatch with titer of 1:100 or 1:1000 in brain). Chicken; mouse hawk (*Buteo vulgaris*); pigeon, owl, goose; stork (*Ciconia ciconia*); pheasant (*Diardigallus diardi* B.P.).

Insusceptible species: Reptiles, fish. No mammal is known to be insusceptible.

Geographical distribution: Almost world-wide; absent only from relatively isolated countries or communities.

Induced disease: In dog, after a short incubation period (generally less than 10 days) altered behavior, hiding, lack of obedience, perverted appetite leading to ingestion of straw, paper, earth, and other unaccustomed materials; excitement, unprovoked biting (which may transmit the virus to new hosts), aimless wandering, excess salivation, progressive inability to swallow, alteration of bark to characteristic high pitched tone; staggering, paresis of hindquarters tending toward paralysis and involvement of anterior parts of the body; paralysis of lower jaw, muscular spasms, marked emaciation, death except perhaps in rare instances. In man, after a relatively long incubation period depending on site of implantation (perhaps 27 to 64 days), a uniformly fatal disease, characterized by altered behavior, increased excitability, thirst, pharyngeal spasm with progressive inability to swallow, labored and noisy respiration, death in 3 or 4 days after onset, with or without paroxysm. In sheep, increased sexual desire; tendency to pull wool from other sheep or themselves; light butting, increasing until some ewes, after violent exercise, appear to faint; prostration within 1 to 4 days; death within 2 days from onset of locomotory paralysis. In mouse, experimentally, by intracerebral inoculation, apathy, sluggishness, roughening of hair, tremor, convulsions, prostration, death; sometimes flaccid paralysis of hind legs before death.

Transmission: Usually by bite of dog or some closely related animal; occasionally by bites of cats; rarely by bites

of rabid horses or cattle. Not by contamination of food. In Brazil and Trinidad, probably by the vampire bat, which has been found infected in nature.

Serological relationships: Specific flocculation of rabies virus occurs in the presence of immune serum from rabbit or guinea pig; strains differ in relative amounts of antigenic constituents, as shown by absorption tests. Complement fixation occurs in the presence of virus and guinea-pig antiserum. Neutralizing antibodies are specific.

Immunological relationships: Virus exposed to ultraviolet light tends to lose its virulence before its immunizing potency. Passive immunization succeeds in white mice if antiserum is injected intracerebrally ½ hour before, but not 24 hours before or 2 hours after, virus. Chloroform-treated vaccines more effective than phenolized vaccines, but irritative.

Thermal inactivation: At 60 to 70° C in 15 minutes; in brain tissues, at 45° C in 24 hours.

Filterability: Passes Berkefeld V filter.

Other properties: Viable at least 2 months at 5° C in liquid or dry state. Infective particle between 100 and 240 millimicrons in diameter, by filtration studies.

Literature: Bernkopf and Kligler, Brit. Jour. Exp. Path., *18*, 1937, 481–485; Casals, Jour. Exp. Med., *72*, 1940, 445–451, 453–461; Covell and Danks, Am. Jour. Path., *8*, 1932, 557–572; Dawson, Science, *89*, 1939, 300–301; Am. Jour. Path., *17*, 1941, 177–188; Galloway, Brit. Jour. Exp. Path., *15*, 1934, 97–105; Goodpasture, Am. Jour. Hyg., *1*, 1925, 547–582; Haupt and Rehaag, Ztschr. f. Infektionskrankh., *22*, 1921, 76–88, 104–127; Havens and Mayfield, Jour. Inf. Dis., *50*, 1932, 367–376; *51*, 1932, 511–518; *52*, 1933, 364–373; Henderson, Vet. Med., *37*, 1942, 88–89; Hodes et al., Jour. Exp. Med., *72*, 1940, 437–444; Hoyt et al., Jour. Inf. Dis., *59*, 1936, 152–158; Hurst and Pawan, Lancet, *221*, 1931 (*2*), 622–628; Jour. Path. and Bact., *35*, 1932, 301–321; Johnson and Leach, Am. Jour. Hyg., *32* (B), 1940, 38–45; Kligler and Bernkopf, Proc. Soc. Exp. Biol. and Med., *39*, 1938, 212–214; Am. Jour. Hyg., *33* (B), 1941, 1–8; Leach and Johnson, *ibid.*, *32* (B), 1940, 74–79; Metivier, Jour. Comp. Path. and Therap., *48*, 1935, 245–260; Peragallo, Giorn. di batteriol. e immunol., *18*, 1937, 289–290; Snyman, Onderstepoort Jour. Vet. Sci. and Anim. Indust., *15*, 1940, 9–140; Webster, Am. Jour. Pub. Health, *26*, 1936, 1207–1210; Jour. Exp. Med., *70*, 1939, 87–106; Am. Jour. Hyg., *30* (B), 1939, 113–134; Webster and Casals, Jour. Exp. Med., *71*, 1940, 719–730; *73*, 1941, 601–615; *76*, 1942, 185–194; Webster and Clow, *ibid.*, *66*, 1937, 125–131; Wyckoff, Am. Jour. Vet. Res., *2*, 1941, 84–90.

NOTE: The Negri body, a characteristic cell-inclusion in rabies, has been given the following names under the supposition that it represents stages in the life cycle of a protozoan parasite responsible for the disease: *Neuroryctes hydrophobiae* by Calkins, Jour. Cutaneous Diseases including Syphilis, *25*, 1907, 510; *Encephalitozoon rabiei* by Manouelian and Viala, Ann. Inst. Pasteur, *38*, 1924, 258; and *Glugea lyssae* by Levaditi, Nicolau and Schoen, Ann. Inst. Pasteur, *40*, 1926, 1048.

FAMILY IV. CHARONACEAE *FAM. NOV.*

Viruses of the Yellow-Fever Group, inducing diseases mainly characterized by fever and necrosis of tissues in the absence of obvious macule, papule, or vesicle formation or of conspicuous involvement of nerve cells.

Key to the genera of family **Charonaceae.**

I. Viruses of the Typical Yellow-Fever Group.
 Genus I. *Charon*, p. 1265.
II. Viruses of the Influenza Group.
 Genus II. *Tarpeia*, p. 1268.
III. Viruses of the Hog-Cholera Group.
 Genus III. *Tortor*, p. 1275.

Genus I. **Charon** *gen. nov.*

Viruses of the Typical Yellow-Fever Group, inducing diseases mainly characterized by acute non-contagious fever. Vectors dipterous insects, so far as known. Generic name from Latin *Charon*, ferryman of the Lower World.

The type species is *Charon evagatus spec. nov.*

Key to the species of genus **Charon.**

I. Vectors mosquitoes.
 1. *Charon evagatus.*
II. Vectors unknown, perhaps mosquitoes.
 2. *Charon vallis.*

1. **Charon evagatus** *spec. nov.* From Latin *evagor*, to spread abroad.

Common name: Yellow-fever virus.

Hosts: *HOMINIDAE—Homo sapiens* L., man. Experimentally, also *Cercopithecus tantalus* Ogilby; *C. aethiops*, African guenon (symptomless); *Cercocebus torquatus* (Kerr), collared mangabey; *Mus musculus* L., mouse; *Microtus agrestis*, field vole; *Sciurus vulgaris* L., red squirrel; *Macaca mulatta* (Zimmermann), rhesus monkey; *Macacus sinicus* Indian crown monkey; *M. cynomolgus*; *M. speciosus*; *Erinaceus europaeus*, hedge hog; *Gallus gallus* (L.), chicken (tolerant); *Dasyprocta aguti*, agouti (serial passage fails).

Insusceptible species: Cat, ferret, rabbit, rat; *Cricetus auratus*, golden hamster; *Apodemus sylvaticus*, wood vole; *Evotomys glareolus*, bank vole; pigeon, canary, pipistrelle bat; *Cricetomys gambianus*, pouched rat; dog, goat.

Geographical distribution: Tropical regions in general, especially Central and South America, West Indies, West Africa; anti-mosquito campaigns have tended to eradicate yellow-fever virus from parts of its former range.

Induced disease: In man, mild cases may occur, especially in natives where the disease is endemic, but in Europeans generally sudden fever without marked change in pulse rate after a 3 to 6-day incubation period; severe frontal headache, pains in the loin and legs and epigastric pain; gradual decrease in temperature to 98 or 99° F, weakening of pulse and slowing of heart beat in the absence of further temperature changes; jaundice, especially in sclerae, often in skin; albumen in urine, later bile-pigments also present; hemorrhages frequent especially in alimentary canal; fatty and necrotic changes in the liver; acute degeneration of renal parenchyma, splenic congestion; death may occur in the early acute state, but is more likely about the

fifth or sixth day; relapses may occur until 2 or 3 weeks after onset; case mortality varies from 10 to 90 per cent in different epidemics. A transitory immunity due to transfer of serum antibodies through the placenta protects offspring of immune mothers for a short time.

Transmission: By mosquitoes, *Aëdes aegypti* L., *Aëdes leucocelaemus* (D. and S.), *Haemogogus capricorni* Lutz (*CULICIDAE*). The mosquito *Aëdes aegypti* becomes infective, after feeding on a suitable virus source, in 4 days at 37° C, 5 days at 36° C, 6 days at 31° C, 8 days at 25.1° C, 9 to 11 days at 23.4° C, 18 days at 21° C, and 36, not 30, days at 18° C; virus in head, thorax, and abdomen before bites are infective; no evidence of transmission of virus through eggs to offspring or to larvae eating infected adults. Experimentally, also by *Aëdes scapularis* (Rondani), *A. fluviatilis* (Lutz), *A. luteocephalus*, *A. apico-annulatus* (*CULICIDAE*). Experimentally, by feeding, to *Macaca mulatta* and *Cercopithecus aethiops*; by rubbing infected blood into intact and unshaved skin of monkeys.

Serological relationships: Complement-fixation and precipitating antibodies are specific.

Immunological relationships: A specific immunity develops after an attack of the disease or after vaccination with virus grown in media containing tissues of chick embryo minus head and spinal cord.

Thermal inactivation: At 55 to 60° C, not at 50° C, in 10 minutes.

Filterability: Passes membranes of 55, and to some extent membranes of 50, millimicron average pore diameter. Passes Berkefeld V and N, as well as Chamberland F, filters.

Other properties: Particle estimated from filtration data to have a diameter of 17 to 28 millimicrons; by ultracentrifugation data, 19 millimicrons. Inactivated or inhibited by 30-minute exposure to 1:15 formalin, 1:6 ethyl alcohol; 1:300 yellowish eosin, 1:50 sodium oleate, 1:200 *liquor cresolis compositus*; viable after 30-minute exposure at 30° C to 1:7500 mercuric chloride, 1:150 phenol, 1:1500 hexylresorcinol, 1:150 sodium oleate. Sedimentation constant between 18 and 30×10^{-13} cm per sec. per dyne. Viable in 50 per cent glycerine at 2 to 4° C for 58, not for 100, days; in mouse brain at −8° C for 160 days. Viability may be lost on simple drying but retained if drying is carried on *in vacuo* over a desiccating agent.

Strains: Distinctive strains have been isolated. One, to which much study has been given, differs from the typical viscerotropic strain by possessing marked neurotropic or pantropic characteristics.

Literature: Bauer and Hughes, Am. Jour. Hyg., *21*, 1935, 101–110; Bauer and Mahaffy, *ibid.*, *12*, 1930, 155–174; 175–195; Bugher and Gast-Galvis, *ibid.*, *39*, 1944, 58–66; Bugher et al., *ibid.*, *39*, 1944, 16–51; Davis, *ibid.*, *16*, 1932, 163–176; Davis and Shannon, *ibid.*, *11*, 1930, 335–344; Davis et al., Jour. 2. **Charon vallis** *spec. nov.* From Latin *vallis*, valley.

Common name: Rift Valley fever virus.

Hosts: *HOMINIDAE—Homo sapiens* L., man. *BOVIDAE—Bos taurus* L., cow; *Ovis aries* L., sheep; *Capra hircus* L., goat. Experimentally, also *Sciurus carolinensis*, grey squirrel; ferret; *Cricetus auratus*, golden hamster; *Apodemus sylvaticus*, wood mouse; *Microtus agrestis* field vole; *Muscardinus avellanarius*, dormouse; rat; mouse; *Macaca mulatta*; *M. irus*; *Cebus fatuellus*; *C. chrysopus*; *Hapale jacchus*; *H. penicillata*; *Cercopithecus callitrichus* (symptomless); *Erythrocebus patas* (symptomless); *Cercocebus fuliginosus* (symptomless); chick embryo in Tyrode's solution; chorioallantoic membrane of chick embryo.

Insusceptible species: Horse, pig.

Geographical distribution: British East Africa.

Induced disease: In man, benign disease; after 5½ to 6 days, rigors, pains in back, fever for 12 to 36 hours, followed by recovery, with persistence of acquired immune bodies as long as 4 to 5 years after infection. In sheep (lambs), dullness, rapid respiration, collapse and death in a few hours or a chronic course; focal necrosis in liver. In chorioallantoic membrane of chick embryo, experimentally, areas of hyperplasia and of necrosis; connective tissue inflamed nearby; liver of embryo mottled with necrotic areas.

Transmission: Not by contacts. Mosquito, *Taeniorhynchus brevipalpis* (*CULICIDAE*), suspected as possible vector.

Serological relationships: Antisera for psittacosis, dengue fever, and sandfly fever viruses fail to protect against infection with Rift Valley fever virus. Specific neutralizing antibody in intraperitoneally neutral mixture with Rift Valley fever virus may be dissociated so as to free virus by direct dilution in saline solutions, by intranasal inoculation, or by employment of a small dose, all methods probably implying a dilution effect.

Immunological relationships: No cross immunity with yellow-fever or dengue-fever viruses. If Rift Valley fever virus is inoculated into *rhesus* monkey simultaneously with yellow-fever virus, the animal tends to be protected against death from yellow fever (interference effect), but one-day earlier inoculation of Rift Valley fever virus does not protect.

Thermal inactivation: At 56° C in 40, not 20, minutes.

Filterability: Passes Berkefeld V, N, and W filters; passes Chamberland L_2, L_3, L_5, L_7, L_{11} and occasionally L_{13} filters; passes membranes 150 millimicrons in average pore diameter freely, 90 millimicrons with difficulty, 70 millimicrons not at all.

Other properties: Viable at least 8 months at 4° C, more than 4 weeks dry in liver tissues, 6 months in ½ per cent carbolic acid at 4° C. Diameter of infective particle estimated from filtration studies to be between 23 and 35 millimicrons.

Strains: A neurotropic strain immunizes lambs without producing obvious illness, if given subcutaneously.

Literature: Broom and Findlay, Brit. Jour. Exp. Path., *14*, 1933, 179–181; Daubney et al., Jour. Path. and Bact., *34*, 1931, 545–579; Findlay, Trans. Roy.

Genus II. **Tarpeia** *gen. nov.*

Viruses of the Influenza Group, inducing diseases characterized principally by involvement of the respiratory tract. Generic name from Latin *Tarpeia*, name of a Roman maiden who treacherously opened a citadel to an enemy.

The type species is *Tarpeia alpha spec. nov.*

Key to the species of genus **Tarpeia.**

I. Infecting man principally.
  1. *Tarpeia alpha.*
  2. *Tarpeia beta.*
  3. *Tarpeia premens.*

II. Affecting feline species.
  4. *Tarpeia felis.*

III. Affecting domestic cattle (calves).
  5. *Tarpeia vitulae.*

IV. Affecting canine species.
  6. *Tarpeia canis.*
  7. *Tarpeia vulpis.*

V. Affecting ferrets.
  8. *Tarpeia viverrae.*

VI. Affecting domestic fowl.
  9. *Tarpeia avium.*

1. **Tarpeia alpha** *spec. nov.* From first letter of Greek alphabet.

Common name: Influenza A virus; swine filtrate-disease virus.

Hosts: *HOMINIDAE—Homo sapiens* L., man. *SUIDAE—Sus scrofa* L., domestic swine. Experimentally, also ferret, mouse, *Macacus irus*, hedgehog, rabbit (inapparent infection), guinea pig (inapparent infection), rat (inapparent infection); *Mustela sibirica* Milne-Edwards, Chinese mink; *Sciurotamius davidianus* Milne-Edwards, David's squirrel; chick embryo (some strains produce visible lesions at 36.5° C on chorioallantoic membrane); minced chick embryo in Tyrode's solution.

Insusceptible species: *Callosciurus caniceps canigenus* Howell, Chekiang squirrel; *Eutamias asiaticus senescens* Miller, chipmunk.

Geographical distribution: World-wide.

Induced disease: In man, headache, dizziness, with shivering and muscular pains; rise of temperature on the second day, sometimes with fall on the third and elevation again later; often complicated by bronchitis and bronchopneumonia; hemorrhagic and edematous lobular consolidation in lungs; virus most easily recoverable from nasopharyngeal washings, but also from nasal secretions and lungs. In swine, virus alone produces only a mild malady (filtrate disease);

in the presence of *Haemophilus influenzae suis* a severe malady occurs under both natural and experimental conditions; it involves fever, cough, and prostration; many infected animals die. Lungworms, *Metastrongylus elongatus* and *Choerostrongylus pudendotectus* (*METASTRONGYLIDAE*), from infected swine harbor virus at least 2 years, living meantime in earthworms, such as *Allolobophora caliginosa* (*LUMBRICIDAE*), which are eaten eventually by swine. The swine are refractory to viral infection during May, June, July, and August, but the disease may be invoked later by successive intramuscular injections of *Haemophilus influenzae suis* or other stimuli, such as feeding embryonated *Ascaris* ova. In infected swine, virus occurs in turbinates, tracheal exudates, and lungs; not in spleen, liver, kidney, mesenteric lymph nodes, brain, blood, or mucosa of colon. Neutralizing antibodies appear later (7th to 10th day) in the mild filtrate disease than in typical swine influenza, in which they appear about the 6th to the 7th day; maximum titer on 14th to 27th day. Experimentally in mouse, not contagious as in swine and not dependent on the coexistence of a bacterial component; death of epithelium of respiratory and terminal bronchioles, complete epithelial desquamation, dilatation of bronchioles, collapse of alveoli; in healing, widespread epithelial proliferation. Experimentally in ferret, moderate apathy, lack of appetite, pallor of nose, variable catarrhal symptoms; at acute stage of disease, necrosis of respiratory epithelium of nasal mucous membrane, with desquamation of superficial cells, exudation into air passages and inflammatory reaction in the submucosa; repair follows, beginning on the 6th day after infection and becoming essentially complete at the end of 1 month; after recovery, the ferret is immune for 3 months or more, with subsequent waning of resistance; subsequent subcutaneous inoculations of virus restore immunity.

Transmission: Presumably by droplets; for example between cages of ferrets as close as 5 feet apart, even to levels 3 feet higher than cage of diseased individuals. Experimentally, from washings of human throats to ferret, mouse, chick embryo (by amniotic route and to allantoic membrane); in mice, by contact and by inhalation of fine droplets.

Serological relationships: Neutralizing antibodies common in human sera from individuals above 10 years of age; rarer in sera from young children; strongly effective for homologous, weak for heterologous, virus in convalescent sera. Soluble complement-fixing antigen of swine strain has components in common with antigens of human strains (PR8 and WS). Complement fixation best 10 to 14 days after onset in man. Inactivating capacity of nasal secretions proportional to level of neutralizing antibodies in blood. Agglutination of red cells by influenza virus is inhibited quantitatively by specific antiserum.

Immunological relationships: Specific immunization of ferrets, without obvious disease, occurs as a result of intranasal inoculation of egg-passage influenza virus that is not transmissible from ferret to ferret. In mice, immunizing dose is directly proportional to degree of induced immunity; immunity to the strain used in immunization is more effective in general than that to heterologous isolates of the virus.

Filterability: Passes Berkefeld V filter.

Other properties: Particle size estimated as 80 to 120 millimicrons by filtration studies; 80 to 99 millimicrons by ultracentrifugation ($S_{20°} = 724 \times 10^{-13}$ cm per sec. per dyne); electron micrographs show bean or kidney-shaped particles, or round particles with central dense spot, averaging 77.6 millimicrons in diameter. Inactivated by oleic, linolic and linolenic acids without loss of immunizing ability. Inactivated by ultraviolet radiation.

Hyg., *24*, 1936, 407–413.

2. **Tarpeia beta** *spec. nov.* From second letter of Greek alphabet.

Common name: Influenza B virus.

Hosts: *HOMINIDAE—Homo sapiens* L., man. Experimentally, also ferret, mouse, chick embryo.

Geographical distribution: United States, England.

Induced disease: In man, subclinical disease or one resembling that induced by influenza A virus. In chick embryo, experimentally, virus increases in entodermal cells lining allantoic cavity.

Serological relationships: Not neutralized by antiserum to influenza A virus. Specific neutralization and complement-fixation reactions. Rapidly adsorbed by normal chicken-blood red cells (95 per cent in 15 minutes); released in 4 hours essentially completely; the process is then repeatable with fresh red cells.

Other properties: Particle circular or bean-shaped in outline, with average diameter of 97.3 millimicrons in electron micrographs; of 99.8 millimicrons by centrifugation studies.

Literature: Burnet, Austral. Jour. Exp. Biol. and Med. Sci., *19*, 1941, 291–295; Francis, Science, *92*, 1940, 405–408; Proc. Soc. Exp. Biol. and Med., *45*, 1940, 861–863; Hirst, Jour. Exp. Med., *76*, 1942, 195–209; Lush et al., Brit. Jour. Exp. Path., *22*, 1941, 302–304; Nigg et al., Am. Jour. Hyg., *35*, 1942, 265–284; Sharp et al., Jour. Immunol., Virus Res. and Exp. Chemother., *48*, 1944, 129–153.

3. **Tarpeia premens** *spec. nov.* From Latin *premere*, to oppress or afflict.

Common name: Common-cold virus.

Hosts: *HOMINIDAE—Homo sapiens*

L., man. Experimentally, also chimpanzee, chick embryo.

Geographical distribution: World-wide except in conditions of isolation of small communities.

Induced disease: In man, incubation period about 48 hours; mild malady; running nose in 81 per cent of cases, obstruction of nostrils in 44 per cent, sudden onset in 37 per cent, cough in 31 per cent, headache in 19 per cent, sore throat in 14 per cent, fever in 13 per cent, inflammation of eyes in 12 per cent; changes in weather, especially during a warm season, predispose to the disease; no correlation between susceptibility and outdoor exercise, exposure to fresh air while sleeping, eye color, adenotonsillectomy, or size of frontal sinus. Incidence inversely proportional to daily hours of sunshine and atmospheric temperature. Fitness (defined by speed of oxygen replacement) correlated with relative freedom from colds. Effect of rest during disease favorable, reducing complications, length of fever, duration of illness, and period off duty.

Immunological relationships: After attack, specific immunity for about 7 weeks (minimum period 23 days); then exposure to chilling may cause a relapse, but an isolated community tends to lose the virus during the refractory period.

Filterability: Passes Berkefeld V and W as well as Seitz filters.

Other properties: Viable at least 13 days at ice-box temperature, anaerobically; at least 4 months frozen and dried *in vacuo*. Gum acacia tends to stabilize virus in chick-embryo tissue medium.

Literature: Dochez et al., Jour. Exp. Med., *63*, 1936, 559–579; Doull et al., Am. Jour. Hyg., *13*, 1931, 460–477; *17*, 1933, 536–561; Gafafer, *ibid.*, *13*, 1931, 771–780; *16*, 1932, 233–240, 880–884; Jour. Inf. Dis., *51*, 1932, 489–492; Gafafer and Doull, Am. Jour. Hyg., *18*, 1933, 712–726; Hyde and Chapman, *ibid.*, *26*, 1937, 116–123; Kneeland et al., Proc. Soc. Exp. Biol. and Med., *35*, 1936, 213–215; Le Blanc and Welborn, Am. Jour. Hyg., *24*, 1936, 19–24; Locke, Jour. Inf. Dis., *60*, 1937, 106–112; Long and Doull, Proc. Soc. Exp. Biol. and Med., *28*, 1930, 53–55· Maughan and Smiley, Am. Jour. Hyg., *9* 1929, 466–472; Noble and Brainard, Jour. Bact., *29*, 1935, 407–409; Palmer, Am. Jour. Hyg., *16*, 1932, 224–232; Paul and Freese, *ibid.*, *17*, 1933, 517–535; Shibley et al., Jour. Am. Med. Assoc., *95*, 1930, 1553–1556; Smiley, Am. Jour. Hyg., *6*, 1926, 621–626; *9*, 1929, 477–479.

4. **Tarpeia felis** *spec. nov.* From Latin *feles*, cat.

Common name: Feline-distemper virus.

Hosts: *FELIDAE—Felis catus* L., domestic cat; *F. pardus*, leopard; *F. tigrina*, American tiger cat; *F. aurata*, African tiger cat; *F. planiceps*, rusty tiger cat; *F. marmorata*, marbled cat; *F. caracal*, caracal lynx; *F. pardalis*, ocelot; lion, tiger, puma relatively insusceptible.

Insusceptible species: Man, dog, ferret, mongcose, rabbit, rat, mouse, guinea pig.

Induced disease: In domestic cat, coughing, sneezing, running eyes and nose, with serous or purulent conjunctivitis, or diarrhea and vomiting; fever to 103 or 105° F; loss of appetite, general weakness; mortality high, especially among young individuals; death usually occurs on the 10th to the 12th day, in extreme cases, however, as early as the 5th or as late as the 35th day; catarrhal congestion in some part of the gastro-intestinal tract is typical; this ranges from a few small patches in the ileum to involvement of the whole small intestine and parts of the large intestine or stomach and esophagus; often enlargement and congestion of abdominal lymph glands, enlargement of spleen, pleurisy, and peritonitis.

Filterability: Passes Berkefeld N and Chamberland L_3 filters.

Transmission: By fomite s.

Immunological relationships: Recovered cats specifically immune.

Other properties: Viable at least 3 weeks in 50 per cent glycerine; attenuated or killed by drying at room temperature, but some immunization is reported if dried virus is injected.

Literature: Dalling, Vet. Record, *15*, 1935, 283–289; Findlay, Vet. Jour., *89*, 1933, 17–20; Hindle and Findlay, Jour. Comp. Path. and Therap., *45*, 1932, 11–26; Verge and Cristoforoni, Compt. rend. Soc. Biol., Paris, *99*, 1928, 312–314.

5. **Tarpeia vitulae** *spec. nov.* From Latin *vitula*, cow-calf.

Common name: Pneumoenteritis virus

Hosts: *BOVIDAE—Bos taurus* L., domestic cattle. Experimentally, also *MURIDAE—Mus musculus* L., mouse.

Geographical distribution: United States.

Induced disease: In cattle (calves), after incubation period of 2 to 4 days, fever increasing rapidly to 40 or 41° C and lasting 3 to 5 days; usually after first day of fever, diarrhea with feces soft, yellow, voluminous, fetid in odor, occasionally blood-tinged or fluid; diarrhea is followed by pneumonia and recovery after disappearance of fever; catarrhal enteritis and a bronchopneumonia usually confined to the anterior lobes of the lungs underlie the symptoms; no inclusion bodies in cells of affected tissues.

Transmission: By pen contacts with infected calves. Experimentally, by intranasal inoculation of calves, using inocula prepared from lungs of infected mice.

Serological relationships: Recovered animals develop neutralizing antibodies.

Immunological relationships: A specific resistance to reinfection is conferred by an attack of the disease.

Filterability: Passes Berkefeld N filter.

Literature: Baker, Cornell Vet., *32*, 1942, 202–204; Jour. Exp. Med. *78*, 1943, 435–446.

6. **Tarpeia canis** *spec. nov.* From Latin *canis*, dog.

Common name: Canine-distemper virus.

Hosts: *CANIDAE—Canis familiaris* L., dog; *Vulpes* sp., fox. *MUSTELIDAE*—ferret.

Insusceptible species: Man, rabbit, guinea pig, white rat, cat.

Geographical distribution: Widespread throughout the world.

Induced disease: In dog, after 4 days from time of infection, fever and a watery discharge from the eyes and nose, sometimes inconspicuous but often profuse; usually diarrhea and wasting followed by recovery or, exceptionally, death. Virus passes from the respiratory tract through the blood stream to its favored sites in vascular endothelium and cells of the reticulo-endothelial system. Nuclear inclusions are found in liver cells, bronchial epithelial cells, glandular cells of the stomach and intestine, and bile-duct epithelial cells; there are also cytoplasmic inclusions in bile-duct epithelial cells.

Transmission: By contact. Probably by air-borne droplets. No arthropod vector is recognized.

Immunological relationships: Dead-vaccine treatment followed by living-virus treatment produces a lasting immunity. Virus inactivated by photodynamic effect in 2 mm layer of 1:50,000 or 1:100,000 methylene blue, exposed 30 minutes at 20 cm from 100 candle-power lamp, still immunizes. Vaccine may be dried.

Filterability: Passes Chamberland L_2 and Mandler filters.

Other properties: Viable in liver tissue at 10° C for 35, not 85, days; in glycerine-saline solution at 10° C, 67 days though deteriorated; in vacuum-dried liver tissue, at 10° C, 90 days. If dried from frozen state, virus is viable in vacuum at least 430 days at 7° C, in oxygen-free nitrogen at least 365 days at 7° C. Viable in 25 per cent sterile horse serum at −24° C more than 693 days.

Literature: Carré, Compt. rend. Acad. Sci., Paris, *140*, 1905, 689–690; Dalldorf,

Jour. Exp. Med., *70*, 1939, 19–27; De Monbreun, Am. Jour. Path., *13*, 1937, 187–212; Dunkin and Laidlaw, Jour. Comp. Path. and Therap., *39*, 1926, 201–212. 213–221; Green and Evans, Am. Jour. Hyg., *29* (B), 1939, 73–87; Laidlaw and Dunkin, Jour. Comp. Path. and Therap., *39*, 1926, 222–230; *41*, 1928, 1–17, 209–227; Perdrau and Todd, *ibid.*, *46*, 1933, 78–89; Siedentopf and Green, Jour. Inf. Dis., *71*, 1942, 253–259; Wharton and Wharton, Am. Jour. Hyg., *19*, 1934, 189–216.

7. **Tarpeia vulpis** *spec. nov.* From Latin *vulpes*, fox.

Common name: Fox-encephalitis virus.

Hosts: *CANIDAE—Vulpes* sp., silver fox. Experimentally, also some, but not all, dogs; coyote.

Insusceptible species: Gray fox, mink, ferret, sheep, laboratory rabbit.

Geographical distribution: United States.

Induced disease: In fox, after 2 days from time of infection, loss of appetite, slight nasal discharge; convulsions with early death or hyperexcitability, blind walking, lethargy, flaccid or spastic paralysis, muscular twitching, fearfulness, weakness, coma and death; many more foxes become infected in epizootics than show obvious disease, some being symptomless carriers; 12 to 20 per cent fatalities may be experienced among young foxes on ranches, 3 to 9 per cent among adults. Intranuclear inclusions in vascular endothelial cells especially in cerebral endothelium; sometimes in hepatic cells and endothelial cells of liver and kidney; no intracytoplasmic inclusions; virus in heart blood, spleen, and brain; in carriers, virus is believed to persist in focal lesions in upper respiratory tract. Experimentally in susceptible dogs, sometimes coryza, discharge from eyes and nose often purulent, commonly fits of excitement, coma, death; recovery rare; cellular infiltration in the central nervous system, focal necrosis of the liver; specific intranuclear inclusions in cells of the vascular endothelium, meningeal cells, reticulo-endothelium, hepatic cells, and occasionally in cortical cells of the adrenal.

Transmission: Experimentally, by skin scarification, intramuscular injection, intraperitoneal injection, inoculation of cisterna, intratesticular injection, inoculation of nasal cavity; not by corneal scarification.

Immunological relationships: Injections of this virus afford no immunity to subsequent infection by canine distemper virus.

Filterability: Passes Berkefeld N filter.

Other properties: Viable in 50 per cent glycerine for several years, in carcass for several days.

Literature: Barton and Green, Am. Jour. Hyg., *37*, 1943, 21–36; Green, Proc. Soc. Exp. Biol. and Med., *23*, 1926, 677–678; Am. Jour. Hyg., *13*, 1931, 201–223; Green and Dewey, Proc. Soc. Exp. Biol. and Med., *27*, 1929, 129–130; Green and Evans, Am. Jour. Hyg., *29* (B), 1939, 73–87; Green and Shillinger, *ibid.*, *19*, 1934, 362–391; Green et al., *ibid.*, *12*, 1930, 109–129; *14*, 1931, 353–373; *18*, 1933, 462–481; *19*, 1934, 343–361; *21*, 1935, 366–388; *24*, 1936, 57–70; Lucas, Am. Jour. Path., *16*, 1940, 739–760.

8. **Tarpeia viverrae** *spec. nov.* From Latin *viverra*, ferret.

Common name: Ferret-distemper virus.

Host: *MUSTELIDAE—Mustela furo*, ferret.

Insusceptible species: Dog, mouse, rat, guinea pig, rabbit.

Geographical distribution: United States.

Induced disease: In ferret, fever to 105 or 106° F, lethargy, loss of appetite, conjunctivitis with exudate closing eyes, sometimes a purulant nasal discharge, weight loss small, sneezing rare, difficulty in breathing, death 14 to 56 days after inoculation (average 20 days), sometimes

preceded by convulsions and other nervous signs; fatality rate 70 to 100 per cent.

Transmission: By cage contacts. By feeding. Experimentally by intranasal, subcutaneous, or intradermal inoculation.

Immunological relationships: In immunized animals, no cross immunity with canine distemper virus nor with human influenza virus.

Thermal inactivation: At 60° C in 30 minutes.

Filterability: Passes Berkefeld N filter.

Other properties: Viable at least 3, but not 5, months in 50 per cent neutral glycerine; at least 4 months when frozen and dried *in vacuo*.

Literature: Slanetz and Smetana, Jour. Exp. Med., *66*, 1937, 653–666; Spooner, Jour. Hyg., *38*, 1938, 79–89.

9. **Tarpeia avium** *spec. nov.* From Latin *aves*, fowl of the air.

Common names: Laryngotracheitis virus; also known as infectious laryngotracheitis virus and as infectious bronchitis virus.

Hosts: *PHASIANIDAE—Gallus gallus* (L.), chicken. Experimentally, also *PHASIANIDAE*—pheasant; F_1 hybrid between male Ringneck pheasant and female bantam chicken; chorioallantoic membrane of developing chicken embryo (with macroscopic lesions on membrane as a result of proliferative and necrotic changes); turkey embryo.

Insusceptible species: Guinea fowl (no evidence of disease on inoculation); white rat, guinea pig, rabbit; embryos of pigeon, guinea fowl, and duck.

Geographical distribution: United States, Canada, Australia.

Induced disease: In domestic chicken, mostly among pullets and yearling hens, loss of appetite, lachrymation from one or both eyes, respiratory distress, hemorrhagic and mucous exudate in lumen of trachea and occasionally in the bronchi; death as a result of asphyxiation or, more often, recovery; recovered birds occasionally carry the virus in the upper respiratory tract for some time (a period of 467 days has been recorded); virus is not found on eggs during an outbreak in a flock, but is always in trachea of an affected bird; intranuclear inclusions in tracheal lesions; virus has special affinity for mucous membrane of eye, nostril, larynx, trachea, cloaca, and bursa of Fabricius; usually affects more than half the birds in a flock, with a mortality of 5 to 60 per cent (averaging between 10 and 20 per cent).

Transmission: By contacts. Experimentally, by intrabursal injection (in bursa of Fabricius) or by rubbing the mucous membrane in the dorsal region of the outer or proctodeal part of the cloaca with a small cotton swab moistened with a suspension of virus.

Serological relationships: Serum from recovered fowl neutralizes virus; dilution tends to reactivate neutralized virus.

Immunological relationships: Experimental infection of cloaca and bursa of Fabricius, especially in 2 to 4-month-old birds, immunizes against infection by subsequent tracheal inoculation.

Thermal inactivation: At 55.5° C in 10 to 15 minutes; at 60° C in 2 to 3 minutes; at 75° C in ¼ to ½ minute; all tests with virus in the presence of tracheal exudate.

Filterability: Passes Berkefeld V and N filters.

Strains: A Victorian strain has been reported as of low virulence for fowls.

Other properties: Inactivated in 5 per cent phenol in 1 minute; in 3 per cent cresol compound in ½ minute; in 1 per cent sodium hydroxide in ½ minute. Viable in tracheal fluid in dark for 75, not 110, days; in light for 6, not 7, hours; in buffer solution at pH 7.4 for 131 days; at 4 to 10° C in dark for at least 217 days; in dried state for at least 661 days. Viable in dead body at 37° C for 22, not 44, hours; at 13 to 23° C for 10, not 15, days; at 4 to 10° C for 30, not 60, days.

Genus III. Tortor *gen. nov.*

Viruses of the Hog-Cholera Group, inducing diseases characterized by involvement of many tissues. Generic name from Latin *tortor*, tormentor.

The type species is *Tortor suis spec. nov.*

Key to the species of genus Tortor.

I. In mammals.
  A. Infecting swine.
    1. *Tortor suis.*
  B. Infecting cattle.
    2. *Tortor bovis.*
  C. Infecting the horse.
    3. *Tortor equorum.*
    4. *Tortor equae.*
  D. Infecting sheep.
    5. *Tortor ovis.*
  E. Infecting cat.
    6. *Tortor felis.*

II. In birds.
    7. *Tortor galli.*
    8. *Tortor furens.*

1. **Tortor suis** *spec. nov.* From Latin *sus*, hog.

Common names: Hog-cholera virus, swine-fever virus.

Host: *SUIDAE—Sus scrofa* L., domestic swine. Warthog (symptomless carrier).

Insusceptible species: Dog, cat, cow, horse, donkey, sheep, goat, rabbit, guinea pig, mouse, rat, goose, hen, duck, pigeon.

Geographical distribution: Almost universal in pig-breeding countries, especially in Europe, the British Isles, North and South America.

Induced disease: In swine, after intramuscular injection, increased temperature and prostration within $2\frac{1}{2}$ to 3 days; later lymph nodes enlarged, sometimes hemorrhagic; hemorrhages under capsule of kidneys. Virus may remain in blood of recovered pigs for 10 months. Acquired immunity is lasting, but most naturally infected animals die in newly infected herds. Virus has been cultured

in minced swine testicle on solid serum-agar and on egg membrane, increase being limited to the living tissues from the swine and furnishing inoculum active in amounts as small as 10^{-5} ml.

Transmission: By feeding. Through air contamination. Rarely by contact. Experimentally, by subcutaneous injection. Urine highly infective. Virus in blood and all tissues early in disease.

Serological relationships: Immune serum affords passive protection.

Thermal inactivation: At 55° C in 30 minutes; at 60° C in 10 minutes. At 72° C in 1 hour in dried blood.

Filterability: Passes Berkefeld filter.

Other properties: Viable in blood in cool, dark place at least 6 years.

Literature: De Kock et al., Onderstepoort Jour. Vet. Sci. and Anim. Indust., *14*, 1940, 31–93; Hecke, Cent. f. Bakt., I Abt., Orig., *126*, 1932, 517–526; Montgomery, Jour. Comp. Path. and Therap., *34*, 1921, 159–191; Röhrer, Arch. Tierheilk., *62*, 1930, 345–372, 439–462; *64*, 1931, 124–143; TenBroeck, Jour. Exp. Med., *74*, 1941, 427–432.

2. **Tortor bovis** *spec. nov.* From Latin *bos*, cow.

Common names: Cattle-plague virus, virus of pestis bovina, runderpest virus, Rinderpest virus.

Hosts: *BOVIDAE—Bos taurus* L., domestic cattle; swine, buffalo, zebu cattle, sheep, goat, camel, deer. Koedoe, eland, bushbuck, duiker, and other antelopes.

Insusceptible species: Man, solipeds, carnivora.

Geographical distribution: Widespread over Asia and the Asiatic islands. At times in Western Europe. Enzootically in Turkey. Periodically in North Africa, especially in Egypt; at times throughout Africa. Not in North America. At times in South America, Australia (suppressed quickly).

Induced disease: In domestic cattle, after 3 to 9 days, febrile reaction, restlessness, loss of appetite, cessation of rumination; fever highest at 5th or 6th day of disease, then temperature drops to normal or subnormal and diarrhea begins; muzzle dry, coat staring, hair dull, skin moist in parts; twitching of superficial muscles, grinding of teeth, arching of back, glairy discharge from nose, redness of mucous membranes; restlessness increases, diarrhea becomes severe with fetid, blood-stained or blackish liquid discharges; weakness, drooping of ears, occasional yawning, coldness of extremities; occasionally excitement precedes weakness; skin may become red and moist, showing protuberances and vesicles, with matted hair; later wrinkling and scab formation; conjunctiva red, eyelids swollen, tears flowing, followed by mucous, then purulent, discharge; sometimes a cough develops and respirations become rapid; red spots inside mouth develop into erosions or ulcers, often confluent; pregnant animals often abort; milk of cows decreases, sometimes becoming yellow and watery. Death is sometimes early (1 to 2 days after first manifestations of disease), more often delayed (4 to 7 days); sometimes animals live 2 or 3 weeks or longer. Disease milder and more chronic where enzootic; morbidity to 100 per cent and mortality to 96 per cent in new areas. Recovered animals show a lasting, sterile mmunity. Urine, feces, nasal and lachrymal discharges, sweat, aqueous humour, cerebrospinal fluid, lymph, emulsions of viscera and muscles, and blood are infective during the course of the disease.

Transmission: By contact, even during prodromal period; by contaminated food, troughs, or other articles. No insect vector is known.

Immunological relationships: One attack confers a lasting immunity, except rarely, when a mild second attack may occur. A calf from a diseased mother may be resistant if pregnancy was far advanced when the disease occurred.

Filterability: Passes Berkefeld V filter candle, with difficulty.

Other properties: Remains infective at

least 2 weeks at 0° C in virulent blood, less than 2 days in hides dried in direct sunlight, 3 days in contaminated wool, as long as 12 days in meat; is inactivated by glycerine, bile, chloroform, formalin, and 2 per cent phenol; is virulent at least 25 days in body of leech, *Hirudo boyntoni* Wharton (*HIRUDIDAE*), fed on sick animal.

Literature: Boynton, Philippine Agr. Rev., *10*, 1917, 410–433; Daubney, Jour. Comp. Path. and Therap., *41*, 1928, 228–248; 263–297; Hornby, *ibid.*, *41*, 1928, 17–24; Pfaff, Onderstepoort Jour. Vet. Sci. and Anim. Indust., *11*, 1938, 263–330; *15*, 1940, 175–184; Weston, Jour. Am. Vet. Med. Assoc., *66* (N.S. *19*), 1924, 337–350.

3. **Tortor equorum** *spec. nov.* From Latin *equus*, horse.

Common names: Horse-sickness virus, African horse-sickness virus, virus of pestis equorum, virus of perdesiekte, virus of South African Pferdesterbe.

Hosts: *EQUIDAE—Equus caballus* L., horse; perhaps *E. asinus* L., donkey. Experimentally, also *CANIDAE—Canis familiaris* L., dog. *CAVIIDAE—Cavia porcellus* (L.), guinea pig. *MURIDAE—Rattus norwegicus* (Erxleben), wild and albino rat; mouse; Angora goat; *Mastomys coucha*, multimammate mouse; *Tatera lobengula*, gerbille; chick embryo (but no virus in hatched chick). Mule and zebra relatively resistant.

Insusceptible species: *HOMINIDAE—Homo sapiens* L., man. *LEPORIDAE—Oryctolagus cuniculus* (L.), rabbit (no observed disease).

Geographical distribution: Africa, especially in coastal regions and river valleys.

Induced disease: In the horse, four types of disease are recognized. Horse-sickness fever, prodromal period 5 to 28 days, rise of body temperature to 105° F in 1 to 3 days, with return to normal temperatures in another day or two; sometimes loss of appetite, redness of conjunctiva, labored breathing, and accelerated pulse; recovery prompt. Dunkop or acute pulmonary horse-sickness, prodromal period of 3 to 5 days, severe dyspnea, fever, coughing, frothing at nostrils; fever to 106° F, breathing rate to 60 a minute, nostrils dilated, head and neck extended, ears drooping, sweating, progressive weakness; often fatal. Dikkop, or cardiac form of horse-sickness, prodromal period 5 to 21 days, fever develops slowly, lasts long; edematous swellings of head and neck, symptoms of cardiac dyspnea, sometimes blood spots on conjunctiva, mucous membranes of mouth and tongue bluish, restlessness; sometimes fatal outcome. Mixed form of horse-sickness, combining features of pulmonary and cardiac types. Horses recovering from natural infections are known as "salted" and possess heightened resistance to the disease.

Transmission: Not by contact. Mosquitoes and biting flies have been suspected as vectors. Experimentally, by intravenous or subcutaneous injection.

Serological relationships: Serologically distinguishable strains exist.

Immunological relationships: Immunity to homologous strain complete after an attack (horse then known as "salted" for that strain), but immunity to heterologous strains incomplete. Antibodies absent from young at birth but as high in titer as in dam within 30 hours, presumably from colostral milk; declining gradually over a period of about 6 months.

Thermal inactivation: At 57.5 to 60° C in 10 minutes.

Filterability: Passes Berkefeld, Chamberland F, and Seitz EK filters.

Other properties: Viable dry at least 15 months. Stable in alkaline solutions (to pH 10), unstable in acid (beyond pH 6.0). Serum-saline solutions preferable to saline solutions for storage. Particle diameter determined as 40 to 60 millimicrons (mean 50 millimicrons) by filtration methods, 45.4 millimicrons by centrifuging. Density 1.25 gm per ml. Isoelectric point at pH 4.8.

Literature: Alexander, Onderstepoort Jour. Vet. Sci. and Anim. Indust., *4*, 1935, 291–322, 323–348, 349–377, 379–388; *7*, 1936, 11–16; *11*, 1938, 9–19; Alexander and DuToit, *ibid.*, *2*, 1934, 375–391; Alexander and Mason, *ibid.*, *16*, 1941, 19–32; Alexander et al., *ibid.*, *7*, 1936, 17–30; DuToit et al., *ibid.*, *1*, 1933, 21–24, 25–50; Henning, in Animal Diseases in South Africa, Central News Agency, Limited, South Africa, *2*, 1932, 516–538; M'Fadyean, Jour. Comp. Path. and Therap., *13*, 1900, 1–20; *23*, 1910, 27–33, 325–328; Nieschulz and DuToit, Onderstepoort Jour. Vet. Med. and Anim. Indust., *8*, 1937, 213–268; Polson, *ibid.*, *16*, 1941, 33–50, 51–66; Nature, *148*, 1941, 593–594; Theiler, Deutsch. tierärztl. Wochenschr., *9*, 1901, 201–203, 221–226, 233–237, 241–242; Report for 1905–1906 of the Govt. Veterinary Bacteriologist, Transvaal Dept. Agr., 1907, 160–162; Jour. Comp. Path. and Therap., *23*, 1910, 315–325.

4. **Tortor equae** *spec. nov.* From Latin *equa*, mare.

Common name: Mare-abortion virus.

Hosts: *EQUIDAE—Equus caballus* L., horse. Experimentally, also Syrian hamster (newborn); tissues of human placenta grafted on the chorioallantois of the chick embryo.

Insusceptible species: Chicken (embryo; no observed susceptibility).

Induced disease: In horse, small, multiple, grayish white areas of necrosis in the livers of aborted fetuses; acidophilic intranuclear inclusions in hepatic cells around these foci, in epithelial cells of bile ducts, and in bronchial epithelium; petechial hemorrhages in the heart, spleen, and lungs; excess fluid in the thoracic cavity.

Transmission: By contact. By living in contaminated stalls.

Literature: Anderson and Goodpasture, Am. Jour. Path., *18*, 1942, 555–561; Dimock, Jour. Am. Vet. Med. Assoc., *96*, 1940, 665–666; Dimock and Edwards, Cornell Vet., *26*, 1936, 231–240; Goodpasture and Anderson, Am. Jour. Path., *18*, 1942, 563–575; Hupbauer, Münch. Tierärztl. Wchnschr., *89*, 1938, 37–38; Miessner and Harms, Deutsche Tierärztl. Wchnschr., *46*, 1938, 745–748.

5. **Tortor ovis** *spec. nov.* From Latin *ovis*, sheep.

Common name: Blue-tongue virus.

Hosts: *BOVIDAE—Ovis aries* L., sheep; *Bos taurus* L., cattle.

Geographical distribution: South Africa.

Induced disease: Both sheep and cattle may carry the virus at times without obvious manifestations of disease or there may be severe manifestations. In sheep, experimentally, diffuse hyperemia of buccal mucosa, especially of lips; then petechiae and ecchymoses followed by excoriations and necrosis of the mucous membrane, especially on lips, tongue, inside of cheeks, dental pad, gums, muzzle, and external nares; sometimes deep seated necrotic ulcers on tongue developing from the more usual superficial necrotic process; mucoid discharge from nostrils, becoming muco-hemorrhagic; commonly frothing at the mouth in early stages of the disease; frequently reddening of skin of lips and nose; rarely whole skin becomes flushed and wool is shed; often swelling of vulva with necrotic changes on borders and petechiae in mucosa; tongue sometimes swollen; lameness common and severe; recovery or death. In cattle, edema of lips and tongue; hyperemia of oral mucosa; multiple hemorrhages in skin, lips, mucous membrane of the lips, tongue, dental pad, buccal cavity, small intestine, myocardium, epicardium, and endocardium, less frequently in the trachea, nasal cavity, bladder, urethra, pulmonary artery, and pleura; localized necrotic areas followed by ulceration on lips, gums, the dental pad, tongue, mucous membrane of the rumen, pylorus of the stomach, and the external nares; scattered skin lesions with reddening, slight exudation, crusting, sloughing of crusts and hair together,

mucoid or mucopurulent discharge from nostrils; prognosis favorable in mild cases, but disease occasionally terminates with death.

Transmission: Not by contact; arthropod vector suspected.

Other properties: Infective particle calculated to be 87 to 105 millimicrons in diameter by sedimentation studies, 100 to 132 millimicrons in diameter by ultrafiltration.

Literature: Bekker et al., Onderstepoort Jour. Vet. Sci. and Anim. Indust., *2*, 1934, 393–507; De Kock et al., *ibid.*, *8*, 1937, 129–180; Henning, in Henning, M. W., Animal Diseases in South Africa, Central News Agency, Ltd., South Africa, 1932, vol. *2*, chapter 27, pages 503–515; Mason and Neitz, Onderstepoort Jour. Vet. Sci. and Anim. Indust., *15*, 1940, 149–157; Nieschulz et al., *ibid.*, *2*, 1934, 509–562; Polson, Nature, *148*, 1941, 593–594.

6. **Tortor felis** *spec. nov.* From Latin *feles*, cat.

Common names: Panleucopenia virus, infectious feline agranulocytosis virus, infectious aleucocytosis virus, feline enteritis virus.

Host: *FELIDAE—Felis catus* L., domestic cat.

Insusceptible species: White mouse, guinea pig, domestic rabbit, ferret; *Citellus richardsonii* (Sabine), ground squirrel.

Geographical distribution: United States, Germany.

Induced disease: In cat, variable effects, some individuals little affected, others listless, recumbent, refusing food, showing some vomiting, diarrhea, nasal and ocular discharges; often death, after a few minutes of fibrillary twitching and terminal clonic convulsions, before there is much loss of weight; sometimes recovery with return of appetite. Profound leucopenia and marked relative lymphocytosis without thrombopenia or appreciable anemia; proliferation of reticulo-endothelial cells of lymph nodes and spleen; intranuclear inclusion in cells of gastro-intestinal mucosa, spleen, lymph nodes, bone marrow, and bronchial mucosa.

Transmission: Perhaps by nasal droplets or contaminated food. No arthropod vector recognized. Experimentally by oral, intragastric, cutaneous, subcutaneous, intraperitoneal, intravenous, and intranasal routes.

Serological relationships: Sera from panleucopenia-immune cats protects against agranulocytosis virus.

Immunological relationships: Cats immune as a result of earlier infection with agranulocytosis virus resist later inoculation with panleucopenia virus. Previous inoculation ineffective if made with hog-cholera virus or fox-encephalitis virus.

Filterability: Passes Berkefeld V, N, and W filters and Seitz EK discs.

Other properties: Remains active in 50 per cent glycerine at least 138 days in tissues; not inactivated by drying while frozen, nor by freezing at about −80° C.

Literature: Hammon and Enders, Jour. Exp. Med., *69*, 1939, 327–352; *70*, 1939, 557–564; Kikuth et al., Cent. f. Bakt., I Abt., Orig., *146*, 1940, 1–17; Lawrence and Syverton, Proc. Soc. Exp. Biol. and Med., *38*, 1938, 914–918; Lawrence et al., Jour. Exp. Med., *77*, 1943, 57–64; Am. Jour. Path., *16*, 1940, 333–354; Syverton et al., Jour. Exp. Med., *77*, 1943, 41–56.

7. **Tortor galli** *spec. nov.* From Latin *gallus*, cock.

Common names: Fowl-plague virus, fowl-pest virus.

Hosts: Chiefly chicken, turkey, goose. Experimentally, also ferret, rhesus monkey, hedgehog, pigeon, duck, canary, mouse, rat, rabbit. Multiplies in embryonated hen's egg; edema, but no discrete primary lesions in chorioallantoic membrane.

Geographical distribution: Widespread throughout Europe, North and South America, Asia.

Induced disease: In chicken, loss of appetite, tendency to leave companions

and seek shade, drooping of wings and tail; eyes closed or partly closed; some dyspnea; in some cases, edema of head and neck; in late stages, sometimes cyanosis of comb and skin; staggering, twitching, or spasms; fever may disappear and temperature become subnormal before death; recovery in about 30 per cent of all cases; linear and punctiform hemorrhages throughout body.

Transmission: Method of natural transmission unknown. The fowl louse, *Goniodes dissimilis* (*PHILOPTERIDAE*), has been suspected as vector (Maggiora and Tombolato, Rendiconti, Accademia delle Scienze dell'Instituto di Bologna, n.s. *27*, 1923, 200–203). Experimentally, by subcutaneous, intramuscular, and intravenous injection.

Serological relationships: Specific neutralizing antiserum does not react with influenza virus. No reaction of fowl-plague virus with antisera specific for canine distemper, influenza, or Rift Valley fever viruses.

Thermal inactivation: At 55° C in 1 hour in whole blood or brain.

Filterability: Passes membrane of average pore diameter 150, not 100, not ordinarily 125, millimicrons. Passes Berkefeld and Chamberland filters.

Other properties: Particle diameter estimated by filtration as 60 to 90 millimicrons; by centrifugation, as 120 to 130 millimicrons. Viable after exposure in 1:10,000 dilution for 10 minutes, in 2 mm layer of 1:50,000 methylene blue, 15 cm from a 300 candle-power filament lamp. Withstands drying. Precipitates from salt-free solutions or in presence of half-saturated ammonium sulphate solutions; virus held to be of globulin nature by Mrowka, Cent. f. Bakt., I Abt., Orig., *67*, 1912, 249–268.

Strains: Variant strains have been produced by intracerebral passage in brains of canaries and mice.

Literature: Bechhold and Schlesinger, Biochem. Ztschr., *236*, 1931, 387–414; Ztschr. Hyg. Infektionskr., *112*, 1931, 668–679; Burnet and Ferry, Brit. Jour. Exp. Path., *15*, 1934, 56–64; Centanni, Cent. f. Bakt., I Abt., Orig., *31*, 1902, 145–152, 182–201; Elford and Todd, Brit. Jour. Exp. Path., *14*, 1933, 240–246; Findlay and Mackenzie, *ibid.*, *18*, 1937, 146–155, 258–264; Findlay et al., Jour. Path. and Bact., *45*, 1937, 589–596; Lépine Compt. rend. Soc. Biol., Paris, *121*, 1936, 509–510; Mackenzie and Findlay, Brit. Jour. Exp. Path., *18*, 1937, 138–145; Nieschulz and Bos, Cent. f. Bakt., I Abt., Orig., *131*, 1934, 1–6; Plotz and Haber, Compt. rend. Soc. Biol., Paris, *125*, 1937, 339–340.

8. **Tortor furens** *spec. nov.* From Latin *furere*, to rage.

Common name: Newcastle-disease virus.

Hosts: *PHASIANIDAE—Gallus gallus* (L.), domestic chicken. *HOMINIDAE—Homo sapiens* L., man (by laboratory accident). Experimentally, also pigeon; chick embryo (with primary lesions and cytoplasmic inclusions in chorioallantoic membrane).

Geographical distribution: England, probably also East Indies, Korea, Japan, India, Australia.

Induced disease: In chicken, acute, febrile, highly contagious, usually fatal disease resembling fowl plague; loss of appetite, crouching attitude, half closed eyes, rapid respirations, watery yellowish-white diarrhea with nauseating odor; death usually between 6th and 8th day. In man, accidentally infected in laboratory by virus sprayed into eye, virus recoverable from temporarily inflamed eye; recovery in 8 days with gradual increase of specific antibodies in blood.

Transmission: By contact between healthy and diseased birds.

Serological relationships: Antiserum effective in neutralizing homologous virus.

Immunological relationships: Chickens immune to infection by fowl-plague virus are susceptible to infection by this virus

and *vice versa*. Immunization to this virus does not decrease susceptibility to comb or mouth form of fowl pox.

Thermal inactivation: At 60° C in 1 hour; not at 56° C in 30 minutes.

Filterability: Passes Berkefeld, Chamberland L_3, and Seitz filters.

Other properties: Particle diameter calculated from filtration experiments to be 80 to 120 millimicrons. Not inactivated in 30 minutes in 1:50,000 methylene blue solution in 2 mm layer 15 cm from a 300 candle-power filament lamp.

Literature: Burnet, Med. Jour. Australia, *30*, 1943, 313–314; Burnet and Ferry, Brit. Jour. Exp. Path., *15*, 1934, 56–64; Doyle, Jour. Comp. Path. and Therap., *40*, 1927, 144–169.

FAMILY V. TRIFURACEAE *FAM. NOV.*

Viruses of the Infectious Anemia Group, inducing diseases mainly characterized by disturbances in balance of blood cells. There is a single genus.

Genus **Trifur** *gen. nov.*

With characters of the family. Generic name from Latin *trifur*, arrant thief. The type species is *Trifur equorum spec. nov.*

Key to the species of genus **Trifur.**

I. Affecting horse.

1. *Trifur equorum.*

II. Affecting fowl.

2. *Trifur gallinarum.*

1. **Trifur equorum** *spec. nov.* From Latin *equus*, horse.

Common name: Equine infectious-anemia virus.

Hosts: *EQUIDAE—Equus caballus* L., horse; *E. asinus* L., donkey. *HOMINIDAE—Homo sapiens* L., man. Experimentally, also *EQUIDAE—Equus asinus* × *E. caballus*, mule. *SUIDAE—Sus scrofa* L., swine.

Insusceptible species: *BOVIDAE—Bos taurus* L., cattle; *Ovis aries* L., sheep; *Capra hircus* L., goat. *CANIDAE—Canis familiaris* L., dog.

Geographical distribution: Europe, Union of South Africa, United States, Canada, Japan; at times in most parts of the world; not Australia.

Induced disease: In horse, progressive anemia with eventual death or clinical recovery and retention of virus; disease may be acute, subacute, or chronic; in acute disease, temperature rise to 104 to 105° F. or even 106 to 107° F, remaining high much of the time until death or change to subacute or chronic form; in the acute form of the disease there is dullness, decreased appetite, drooping of head, flexing of limb not supporting weight; sometimes increase in pulse frequency to 70 or even 100 a minute but oftener rates around 50 a minute; conjunctiva sometimes colored orange, with injection of vessels and petechiae, later becoming muddy colored or pale red, membrane edematous; uncertain gait, trailing of hind feet, prostration, sometimes death; subacute disease milder and with remissions; chronic disease still milder, anemia conspicuous, sometimes death from debility or at end of a febrile attack; blood infective long (3 to 7 years) after clinical recovery; urine infective to horse by mouth. In man, diarrhea alternating with constipation, herpes-like exanthema on abdominal wall, blood sometimes in feces; persistent headache, temperature normal; later, lumbar pains, generalized edema, general debility, loss of flesh, pallor of face and mucosae; filtered blood in 1 ml. amount fatal to horse, inducing infectious anemia; improvement after 2 to 4 years. In swine, experimentally, sometimes no outward and obvious signs of disease but blood abnormal and infective; sometimes severe anemia, fever, prostration, loss of appetite.

Thermal inactivation: At 58 to 60° C in 1 hour.

Filterability: Passes Berkefeld V filter candle.

Other properties: Viable in blood in citrate saline at −2° C for at least a year. Drying does not inactivate in 10 days but does in 1 month.

Literature: DeKock, Union of South Africa, Dept. of Agr., 9th and 10th Reports for 1923, Pretoria 1924, 253–313; Habersang, Monatshefte für prakt. Tierheilk., *30*, 1920, 171–176; Kutsche, *ibid.*, *30*, 1920, 557–568; Peters, Jour. Am. Vet.

Med. Assoc., *66*, 1924, 363–366; Theiler and Kehoe, Union of South Africa, Dept. of Agr., 3rd and 4th Reports of the Director of Veterinary Research, 1915, 215–289.

2. **Trifur gallinarum** *spec. nov.* From Latin *gallina*, hen.

Common name: Fowl-leucosis virus.

Host: *Gallus gallus* (L.), chicken.

Geographical distribution: United States, England, Europe.

Induced disease: In chicken, neurolymphomatosis, with eye lesions (slate gray or bluish color replacing normal bay color of iris), anemia, hemocytoblastosis, lymphoid, erythroid or myeloid types of leucosis; the hemocytoblastosis is followed by infiltration of the central nervous system, peripheral nerves, iris, and many visceral organs by hemocytoblasts and lymphocytes, producing lesions sometimes resembling neoplasms and consisting chiefly of hemocytoblasts (hemocytoblastomata); marrow of radius and ulna becomes hyperplastic; virus in blood plasma, blood cells, emulsions of organs; blood normal in its hydrogen-ion concentration; recovery never complete; some stocks less susceptible than others.

Transmission: By pen contact or contaminated litter. Experimentally by intravenous injection of cell-free filtrates. Not by the mosquitoes, *Culex pipiens* and *Aëdes aegypti* (*CULICIDAE*). Day-old chicks from iritis parents contain the infective agent and show some form of the induced disease in 80 per cent of the progeny if both parents show iritis, in 70 per cent if male is normal, 15 per cent if female is normal.

Serological relationships: Specific neutralizing antibodies are formed in the rabbit as a result of injecting infective materials partly purified by sedimentation in the ultracentrifuge.

Thermal inactivation: At 56° C in 30 minutes.

Filterability: Passes Berkefeld V, N, and W filter candles; 1.5 per cent, but not often 3 per cent, collodion membranes; Seitz asbestos filter.

Other properties: Viable after drying at least 54 days, in glycerine at least 104 days, at 4° C at least 14 days, at −60° C at least 6 months; after freezing and thawing, and after freezing in liquid air. Not viable after 14 days at 37.5° C. Particle diameter between 100 and 400 millimicrons.

Literature: Ellermann and Bang, Cent. f. Bakt., I Abt., Orig., *46*, 1908, 4–5, 595–609; Furth, Proc. Soc. Exp. Biol. and Med., *27*, 1929, 155–157; Jour. Exp. Med., *53*, 1931, 243–267; *55*, 1932, 465–478, 495–504; *58*, 1933, 253–275; *59*, 1934, 501–517; Furth and Miller, *ibid.*, *55*, 1932, 479–493; Hall et al., Am. Jour. Vet. Res., *2*, 1941, 272–279; Jármai, Arch. wissensch. u. prakt. Tierhielk., *62*, 1930, 113–131; Johnson, Virginia Agr. Exp. Sta. Tech. Bull. *56*, 1934, 1–32; Johnson and Bell, Jour. Inf. Dis., *58*, 1936, 342–348; Kabat and Furth, Jour. Exp. Med., *71*, 1940, 55–70; *74*, 1941, 257–261; Lee and Wilcke, Am. Jour. Vet. Res., *2*, 1941, 292–294; Lee et al., Jour. Infect. Dis., *61*, 1937, 1–20; Pierce, Am. Jour. Path., *18*, 1942, 1127–1139; Ratcliffe and Stubbs, Jour. Inf. Dis., *56*, 1935, 301–304.

FAMILY VI. RABULACEAE *FAM. NOV.*

Viruses of the Mumps Group, characterized in general by a special affinity for tissues of the salivary glands. There is a single genus,

Genus I. **Rabula** *gen. nov.*

With characters of the family. Generic name from Latin *rabula*, pettifogger. The type species is *Rabula inflans spec. nov.*

Key to species of the genus **Rabula.**

I. Affecting man.
  1. *Rabula inflans.*

II. Affecting guinea pig.
  2. *Rabula levis.*

III. Affecting hamster.
  3. *Rabula innocuus.*

IV. Affecting rat.
  4. *Rabula exiguus.*

V. Affecting mouse.
  5. *Rabula latens.*

1. **Rabula inflans** *spec. nov.* From Latin *inflare*, to puff up.

Common names: Mumps virus, virus of epidemic parotitis.

Hosts: *HOMINIDAE—Homo sapiens* L., man. Experimentally, also *CERCOPITHECIDAE—Macaca mulatta* (Zimmermann), rhesus monkey. *FELIDAE —Felis catus* L., domestic cat.

Geographical distribution: World-wide.

Induced disease: In man, in order of frequency, parotitis, orchitis, meningo-encephalitis, pancreatitis, or ovaritis; rarely fatal; when parotitis occurs, onset is sudden, with pain in one or both parotid glands, sometimes also with involvement of submaxillary and sublingual glands, swelling and malaise gradually disappearing within a week or 10 days; there is virus in saliva 48 hours after onset; orchitis, less common, is usually unilateral and may be accompanied by some epididymitis. In rhesus monkey, experimentally, acute, non-suppurative parotitis; focal necrosis in acinar epithelial cells of parotid gland, and secondary inflammation; dissemination of lesions within the gland, enlargement of gland to palpation and pitting edema of jowl 6 to 8 days after inoculation, often with a rise of temperature; cytoplasmic inclusion bodies affected glands, staining pink, round or oval, 3 to 10 microns in diameter, often vacuolate, usually surrounded by a narrow clear zone in the cytoplasm; blood and uninoculated salivary gland of affected animal not effective sources of virus.

Transmission: Probably by droplets arising directly from infected individuals. Experimentally, by injecting sterile fluids containing virus into Stenson's duct of parotid gland in *Macaca mulatta.*

Serological relationships: A specific complement-fixing antibody occurs in human and monkey convalescent serum and is demonstrable by the use of monkey-gland antigen.

Immunological relationships: Specific immunity induced by attack; passive immunization rarely successful.

Thermal inactivation: At 55° C in 1 hour.

Filterability: Passes Berkefeld V and N filter candles.

Other properties: Viable in 50 per cent glycerine at 2° C at least 5 weeks, in 50 per cent glycerine at 10° C. at least 7 weeks, dried while frozen at least 7 weeks, in frozen saliva at least 3 weeks.

Literature: Bloch, Am. Jour. Path., *13*, 1937, 939–944; Enders and Cohen, Proc. Soc. Exp. Biol. and Med., *50*, 1942, 180–184; Findlay and Clarke, Brit. Jour. Exp. Path., *15*, 1934, 309–313; Johnson and Goodpasture, Jour. Exp. Med., *59*, 1934, 1–19; Am. Jour. Hyg., *21*, 1935, 46–57; *23*, 1936, 329–339; Am. Jour. Path., *12*, 1936, 495–510.

2. **Rabula levis** *spec. nov.* From Latin *levis*, trifling.

Common name: Guinea-pig salivary-gland virus.

Host: *CAVIIDAE—Cavia porcellus* (L.), guinea pig (only known host; fetus more susceptible than post-natal animal, even if from immune mother).

Insusceptible species: Rabbit, rat, cat, chicken, pigeon, dog, mouse, monkey (*Macacus rhesus*).

Geographical distribution: United States, England.

Induced disease: In guinea pig, submaxillary glands show swollen epithelial cells containing relatively dense acidophilic inclusions of granular material within enlarged nuclei, especially in ducts of the serous portion of the gland, and larger but fewer intracytoplasmic inclusions; experimentally, by intracerebral injection of young guinea pig, prodromal period of about 2 days, then elevation of temperature to 105 or 106° F; a day later, hair raised, animal quiet; subsequently, irritability with tremors and slight convulsive movements; by fifth day, usually prostration, jerking movements, and ensuing death; brain shows no gross lesions but exudate over surface; in meningeal exudate, many cells each containing an acidophilic mass within its nucleus; by subcutaneous injection, virus recoverable after 2 weeks from submaxillary glands, cervical lymph nodes, kidney, and lung, not from blood, liver, or spleen.

Transmission: Experimentally, by inoculation of submaxillary gland or by intracerebral or subcutaneous injection of materials from infected glands; with difficulty from brain to brain. Pilocarpine stimulation increases numbers of inclusions.

Serological relationships: Specific neutralizing antibody is found in blood serum of animals that are carrying virus in their submaxillary glands.

Immunological relationships: Active immunity may be dependent on existence of more or less active lesions.

Thermal inactivation: At 54° C in 1 hour.

Filterability: Passes Berkefeld N filter candle.

Other properties: Viable in 50 per cent glycerine at least 11 days.

Strains: An unusually virulent strain, killing infected animals whatever the route of injection, has been described but not given a distinctive name (Rosenbusch and Lucas, Am. Jour. Path., *15*, 1939, 303–340).

Literature: Andrewes, Brit. Jour. Exp. Path., *11*, 1930, 23–34; Cole and Kuttner, Jour. Exp. Med., *44*, 1926, 855–873; Hudson and Markham, *ibid.*, *55*, 1932, 405–415; Jackson, Jour. Inf. Dis., *26*, 1920, 347–350; Kuttner, Jour. Exp. Med., *46*, 1927, 935–956; Kuttner and T'ung, *ibid.*, *62*, 1935, 805–822; Lucas, Am. Jour. Path., *12*, 1936, 933–948; Markham, *ibid.*, *14*, 1938, 311–322; Markham and Hudson, *ibid.*, *12*, 1936, 175–182; Pearson, *ibid.*, *6*, 1930, 261–274; Scott, Jour. Exp. Med., *49*, 1929, 229–236; Scott and Pruett, Am. Jour. Path., *6*, 1930, 53–70.

3. **Rabula innocuus** *spec. nov.* From Latin *innocuus*, harmless.

Common name: Hamster salivary-gland virus.

Host: *CRICETIDAE—Cricetulus griseus* M. Edw., Chinese hamster.

Insusceptible species: *MURIDAE*—rat; *Mus musculus* L., white mouse.

Geographical distribution: China.

Induced disease: In hamster, no obvious disease externally but inclusion bodies in submaxillary glands.

Thermal inactivation: At 56° C in 30 minutes.

Literature: Kuttner and Wang, Jour. Exp. Med., *60*, 1934, 773-791.

4. **Rabula exiguus** *spec. nov.* From Latin *exiguus*, petty.

Common name: Rat salivary-gland virus.

Host: *MURIDAE*—rat.

Insusceptible species: *MURIDAE—Mus musculus* L., mouse. *CRICETIDAE—Cricetulus griseus* M. Edw., Chinese hamster.

Geographical distribution: China, Canada.

Induced disease: In rat, no obvious disease externally, but intranuclear inclusions in cells of the submaxillary glands.

Literature: Kuttner and Wang, Jour. Exp. Med., *60*, 1934, 773-791; Thompson, Jour. Inf. Dis., *50*, 1932, 162-170.

5. **Rabula latens** *spec. nov.* From Latin *latens*, hidden or lurking.

Common name: Mouse salivary-gland virus.

Host: *MURIDAE—Mus musculus* L., mouse.

Insusceptible species: *MURIDAE*—rat. *CRICETIDAE—Cricetulus griseus* M. Edw., Chinese hamster. *LEPORIDAE*—rabbit. *CAVIIDAE—Cavia porcellus* (L.), guinea pig.

Geographical distribution: China, Canada, United States.

Induced disease: In mouse, no obvious disease externally, but inclusion bodies in acinar tissue of serous and mucous portions of submaxillary glands; occasionally also in duct cells or alveolar cells of parotid gland; affected cells hypertrophied. In Swiss white mice, extensive lesions in liver and spleen but emulsions of these organs fail to infect; rare pancreatic lesions.

Transmission: Experimentally, by intraglandular, subcutaneous, intraperitoneal, intratesticular or intracerebral inoculation; inclusion bodies appear in salivary glands irrespective of site of inoculation.

Thermal inactivation: At 60° C in 30 minutes.

Filterability: Passes Berkefeld V filter candle.

Literature: Kuttner and Wang, Jour. Exp. Med., *60*, 1934, 773-791; McCordock and Smith, *ibid.*, *63*, 1936, 303-310; Thompson, Jour. Inf. Dis., *58*, 1936, 59-63

SUPPLEMENT NO. 3

PLEUROPNEUMONIA AND PLEUROPNEUMONIA-LIKE ORGANISMS (BORRELOMYCETACEAE)

Louis Dienes

Boston, Mass.

May, 1945

THE ORGANISM OF CONTAGIOUS BOVINE PLEURO-PNEUMONIA AND RELATED ORGANISMS*

INTRODUCTION

The organism of bovine pleuropneumonia is similar in certain respects to filterable viruses. Both in infected tissue and in cultures, small elements are present which pass through filters that retain bacteria. The organism is not stained well by the usual bacterial stains and can be made visible only by using special methods. Bovine pleuropneumonia and other diseases caused by similar organisms were originally attributed to filterable viruses. These organisms are different from viruses in an important point; namely, they grow on suitable media in the absence of living host cells. The cultures consist of pleomorphic elements, the nature of which has only slowly become apparent. By the studies of Nowak (Ann. Inst. Past., *43*, 1929, 1330), Turner (Jour. Path. and Bact., *41*, 1935, 1) and Klieneberger and Smiles (Jour. Hyg., *42*, 1942, 110), it has been established that the pleomorphic forms are part of a reproductive cycle different from binary fission. The small elements in the cultures swell up into large round forms which reproduce the small elements within their membranes. The morphology of the organism is further complicated by the fact that long branching filaments are present in freshly isolated bovine strains. These break up into granules or parts of the filaments swell up into large round forms. In the judgment of some investigators, these properties, in addition to unusual softness and fragility, exclude the organism of bovine pleuropneumonia and similar organisms from the order of true bacteria. Ledingham (Jour. Path. and Bact., *37*, 1933, 393) has classified them with the *Actinomyces*. Later, Turner (Jour. Path. and Bact., *41*, 1935, 1) placed them in an independent order, *Borrelomycetales*, while Sabin (Bact. Rev., *5*, 1941, 58) has even placed them in an independent class, *Paramycetes*.

The observations of the present author give support to the classification of Buchanan (Jour. Bact., *3*, 1918, 44) who placed the genus *Asterococcus* Borrel et al. with the organism of bovine pleuropneumonia (*Asterococcus mycoides* Borrel et al.) as type, together with the genus *Haemophilus* Winslow et al. in subtribe *Haemophilinae* Buchanan of the tribe *Bacterieae* Trevisan emend. Buchanan. In many strains of the pleuropneumonia

*Common names have been used through Supplement No. 3 (except for *Asterococcus* and *A. mycoides*) as the author believes that a more suitable nomenclature than any thus far proposed should be developed when agreement is reached as to the nature of these organisms. Specific names that have been proposed are given merely as a matter of record. No new names have been introduced.

group, the small forms appear in appropriate preparations as small bipolar stained bacilli. The transformation of the bacilli to round bodies of variable size often occurs in bacterial cultures and is not specific for the pleuropneumonia group. Furthermore, it has been observed in several species of bacteria that they reproduce in the large round forms in a manner similar to that observed in the pleuropneumonia group. Thus the form variation and reproductive processes observed in the pleuropneumonia group are not specific to this group. They represent general bacterial properties and should be included in the definition of the true bacteria.

According to these considerations, the organisms belonging to the pleuropneumonia group are small, Gram-negative bacilli often showing bipolar staining and their distinctive characteristic is the tendency to swell up into round forms and multiply by the reproduction of bacilli in the round forms. Their habitat is in the mucous membranes of animals and man and many of them are pathogenic. They are exacting in their media requirements and usually require fresh animal serum for their growth. These properties indicate a close similarity to the species now included in the genera *Pasteurella* and *Haemophilus*. The pleuropneumonia group might well be classified in the same or a closely related family. It is uncertain whether the strains isolated from earth and sewage should be classified with the strains isolated from animals and men. The soil and sewage strains are less soft, stain more easily and grow abundantly without animal serum. The strains isolated from bacterial cultures are most probably variant forms of the bacteria and should be classified with the parent organisms.

The viruses of psittacosis and lymphogranuloma present similarities to the pleuropneumonia group both in morphology and in their methods of reproduction. This gives added weight to the thought that the pleuropneumonia group represents an intermediary stage in the evolution of the small, Gram-negative bacteria of the mucous membranes into the filterable viruses.

I. THE PLEUROPNEUMONIA GROUP.

(*Borrelomycetaceae* Turner, Jour. Path. and Bact., *41*, 1935, 25; *Parasitaceae* Sabin, Bact. Rev., *5*, 1941, 58.)

The organisms are soft and fragile. Without special precautions they are often distorted or entirely destroyed in microscopical preparations. The cultures contain pleomorphic elements: Small granules, bacilli, bacillary filaments and round forms varying in size from a few tenths of a micron to 10 microns or more. Autolyzed round forms may coalesce into large empty blebs. The round forms are part of a reproductive cycle. They are produced by the swelling of the bacillary forms and filaments and reproduce granules or filaments by inside segmentation or multiple germination. In freshly isolated bovine strains, the filaments show apparent or true branching and reproduce the small forms by segmentation. The smallest growing units may not be larger than .15 to .28 micron and pass through filters that retain bacteria. On agar, tiny colonies (0.1 to 0.6 mm) develop in great numbers. The colonies invade the agar and after 2 to 5 days growth have an opaque center embedded in the agar and a thin peripheral zone. The surface has a rugged or granular appearance due to the development and autolysis of the large forms. After a few days growth, the cultures usualy show pronounced autolysis. The parasitic strains require fresh animal serum for growth. There is a single genus.

Genus I. **Asterococcus** *Borrel et al.*

(Borrel, Dujardin-Beaumetz, Jeantet and Jouan, Ann. Inst. Past., *24*, 1910, 179; *Coccobacillus* Martzinovski, Ann. Inst. Past., *25*, 1911, 91; *Micromyces* Frosch, Arch. f. wissensch. u. prakt. Tierheilk., *49*, 1923, 35 and 273; not *Micromyces* Dangeard, Le Botaniste, *1*, 1888, 55; *Mycoplasma* Nowak, Ann. Inst. Past., *43*, 1929, 1349; *Asteromyces* Wroblewski, Ann. Inst. Past., *47*, 1931, 105; *Borrelomyces* Turner, Jour. Path. and Bact., *41*, 1935, 25; *Bovimyces* Sabin, Bact. Rev., *5*, 1941, 57.)

Characters as for the family.

The type species is *Asterococcus mycoides* Borrel et al.

1. **Asterococcus mycoides** Borrel et al. (Le microbe de la péripneumonia, Nocard and Roux, Ann. Inst. Past., *12*, 1898, 240; Borrel, Dujardin-Beaumetz, Jeantet and Jouan, Ann. Inst. Past., *24*, 1910, 168; *Coccobacillus mycoides peripneumoniae* Martzinovski, Ann. Inst. Past., *25*, 1911, 914; *Micromyces peripneumoniae bovis contagiosae* Frosch, Arch. f. wissensch. u. prakt. Tierheilk., *49*, 1923, 35 and 273; *Mycoplasma peripneumoniae* Nowak, Ann. Inst. Past., *43*, 1929, 1530; *Asteromyces peripneumoniae bovis* Wroblewski, Ann. Inst. Past., *47*, 1931, 94; *Borrelomyces peripneumoniae* Turner, Jour. Path. Bact., *41*, 1935, 1; *Bovimyces pleuropneumoniae* Sabin, Bact. Rev., *5*, 1941, 57.)

Morphology of cells and appearance of agar cultures correspond with the description given for the group.

Broth cultures are slightly opalescent and, upon shaking, the cultures of fresh strains exhibit silk-like whorls, due to the presence of long chains and filaments. The cultures after prolonged incubation consist of small granules.

Biochemical activity: Old colonies on serum agar develop a brownish color. Freshly isolated strains reduce hemoglobin. Glucose, fructose, mannose, maltose, and dextrin are fermented with the production of acid but no gas. The cultures are bile soluble.

The strains isolated from cattle are homogeneous in serological reactions and distinct from the other members of the group.

Habitat: It is the causative agent of contagious bovine pleuropneumonia. The disease can be transferred to sheep, goats and water buffaloes, but not to mice, rats, rabbits or other experimental animals.

2. **The organism of agalactia of sheep and goats.** (Le microbe d'agalaxie contagieuse, Bridré and Donatien, Ann. Inst. Past., *39*, 1925, 925; *Anulomyces agalaxiae* Wroblewski, Ann. Inst. Past., *47*, 1931, 111; *Borrelomyces agalactiae* Turner, Jour. Path. and Bact., *41*, 1935, 25; *Capromyces agalactiae* Sabin, Bact. Rev., *5*, 1941, 57.)

These organisms are very similar to the former organisms in morphology, appearance of the cultures and growth requirements. Usually the growth is less vigorous, the colonies remain smaller, and the elements of the cultures are more delicate and less easily visible than those of bovine pleuropneumonia. Characteristic crystals develop in the cultures.

Serologically and immunologically this species is distinct from the bovine species.

It is the cause of a systemic disease in sheep and goats with involvement of the joints, eyes, and, in lactating animals, the mammary glands. Other species are not susceptible.

3. **Pleuropneumonia-like organisms in dogs.** (*Asterococcus canis*, Types I and II, Schoentensack, Kitasato Arch. Exp. Med., *11*, 1904, 227; *13*, 1936, 175; *Canomyces pulmonis* I and II, Sabin, Bact. Rev., *5*, 1941, 57.)

Both types produce slight uniform opalescence in broth. Type I grows in granules and coarse colonies and is apparently pathogenic for dogs. Type II grows in somewhat larger granular colonies.

They are serologically distinct from each other and from the other members of the pleuropneumonia group.

The connection of these organisms with distemper is not proven.

4. **Pleuropneumonia-like organisms in rats.** L_3 (Klieneberger and Steabben, Jour. Hyg., *37*, 1937, 143; Jour. Hyg., *40*, 1940, 223; *Murimyces pulmonis* Sabin, Bact. Rev., *5*, 1941, 57.)

L_4 (Klieneberger, Jour. Hyg., *38*, 1938, 458; *Murimyces arthritidis* Sabin, *loc. cit.*)

The pyogenic virus of Woglom and Warren (Jour. Exp. Med., *68*, 1938, 513) and L_7 of Findlay, MacKenzie, MacCallum and Kleineberger (Lancet, *237*, 1939, 7) are identical with L_4. The organisms isolated from infected joints by Beeuwkes and Collier (Jour. Inf. Dis., *70*, 1942, 1) and Preston (*ibid.*, *70*, 1942, 180) probably are identical with L_4 but they were not typed serologically.

The requirements for growth, the appearance of colonies and the morphology are very similar to those of the type strain with the difference that long filaments are not observed either in liquid or solid media.

The strains isolated from rats belong to two serological types. L_3 was cultivated from chronic lung abscesses, but the number of strains typed is not sufficient to ascertain that all strains isolated from this source belong to one type. The L_3 strains are not pathogenic for rats in artificial infection. They produce suppuration in mice when they are injected with agar.

L_4 which is serologically different from L_3 was cultivated from abscesses and spontaneous polyarthritis. It produces polyarthritis both in mice and rats. It is not infectious in monkeys, rabbits and guinea pigs. Both L_3 and L_4 were recovered from the brains of mice kept in the same room with rats.

According to Klieneberger, L_3 usually produces somewhat larger and coarser colonies than L_4; L_3 grows in broth in small granules, while L_4 produces an opalescent growth.

5. Pleuropneumonis-like organisms in mice. (Sabin, Science, *88*, 1938, 575, and Bact. Rev., *5*, 1941, 1; Findlay, Klieneberger, MacCallum and MacKenzie, Lancet, *235*, 1938, 1511.) A strain isolated by Sullivan and Dienes (Proc. Soc. Exp. Biol. and Med., *41*, 1939, 620) is identical with Type A.

Five groups of strains, distinct serologically, and, to a certain extent, distinct also in their pathological properties, have been isolated from mice. These are types A, B, C, D, and E of Sabin. The strains are closely similar to each other and to the rat strains. It is questionable whether the slight differences in the appearance of the colonies and in the morphology of the cultures are of significance.

Type A (*Musculomyces neurolyticus* Sabin) is usually present in the conjunctiva and was isolated also from the lung and brain. Intercerebral injection of Type A produces in mice a characteristic rolling disease due to a toxin which is also present in broth cultures. Intravenous injection produces a transient polyarthritis without damage to the cartilage or ankylosis. Type A is serologically similar to L_5 of Klieneberger, (Jour. Hyg., *40*, 1940, 204).

Type B (*Musculomyces arthrotropicus* Sabin) was isolated from the brain and from the nasal mucosa. It produces no rolling disease and no soluble toxin. In mice, intravenous injection usually produces a chronic arthritis often leading to ankylosis.

Types C, D and E (*Musculomyces histotropicus* Sabin) were isolated from the same location as Type B and produce similar arthritic lesions. They are serologically distinct from Type B and from each other (Sabin, Science, *90*, 1939, 18 and Sabin and Johnson, Proc. Soc. Exp. Biol. and Med., *44*, 1940, 569).

L_6 isolated from mice by Findlay et al. (Trans. Roy. Soc. Trop. Med. Hyg., *33*, 1939–40, 6) and the strains of Edward (Jour. Path. and Bact., *50*, 1940, 409) were not compared serologically with the types of Sabin.

6. Pleuropneumonia-like organisms in man. (Dienes, Proc. Soc. Exp. Biol. and Med., *44*, 1940, 468; Beveridge, Med. Jour. of Australia, *30*, 1943, 479; Kleineberger, Lancet, *2*, 1945, 46.)

They are present in about 30 per cent of women in the genitals and they were isolated from suppurative processes originating from this source. In men they were found in urethritis, cystitis and chronic prostatitis.

The appearance of the colony, the morphology and growth requirements correspond with the animal strains. The human strains grow less abundantly in serum broth than the animal strains.

One strain was found by Sabin (Proc. Soc. Exp. Biol. and Med., *44*, 1940, 569) to be serologically different from the strains isolated from rats and mice. It is not known whether the strains are serologically uniform. There is a slight variation in colony form, in the tendency to grow in filaments, and in the abundance of growth, but the variation between the strains is less than the variation due to slightly different cultural conditions.

Mice and rats are usually not susceptible to infection with the human strains; however, several young mice from a single litter were killed in three to six days by subcutaneous or intraperitoneal injection of one strain.

7. Pleuropneumonia-like organisms in chick embryos. (Van Herick and Eaton, Jour. Bact., *50*, 1945, 47.)

Organisms have been isolated from chick embryos which conform to the pleuropneumonia group with regard to morphology, the appearance of colonies on agar and filterability. The cultures agglutinated red blood cells from various animals. The relation of this strain to the coccobacillary bodies of Nelson (see Section II) has not been studied.

II. ORGANISMS OF UNCERTAIN CLASSIFICATION.

Similar to the Pleuropneumonia Group.

1. **Coccobacillary bodies of Nelson.** (Nelson, Science, *82*, 1935, 43; Jour. Exp. Med., *65*, 1937, 833; Jour. Exp. Med., *72*, 1940, 615.)

Nelson isolated a small bacillary organism apparently connected with coryza and infectious catarrh from the nasal passages of fowls and from the nasal passages and the middle ear of mice and rats. Their size appeared to be 0.3 to 0.4 micron in microscopical preparations and they passed through a filter with a pore size of 640 millimicrons. They were isolated in tissue cultures but they grow also in the cell-free and heated supernatant fluid. The freshly isolated cultures did not grow on blood or on artificial media; however, after 120 passages in tissue cultures the fowl coryza bodies grew on blood agar slants. On ascitic agar this strain forms colonies very similar to those of the pleuropneumonia group with a dark center surrounded by a thin periphery. The organisms in the top layer are sometimes considerably enlarged, but no web-like structure is produced. The organism is less soft and the individual organisms maintained their form in the preparations as do bacteria, and the tendency to grow into the agar is less pronounced than in the pleuropneumonia group. The organism isolated from rats is more pleomorphic than the others.

The coccobacillary bodies were not studied with methods appropriate to determine whether they belong to the pleuropneumonia group and whether the mouse and rat strains are identical with the pleuropneumonia-like organisms isolated from mice and rats.

2. **Filterable organisms from sewage and soil.** (Fam. *Saprophytaceae* Sabin, Genus *Sapromyces* Sabin, Bact. Rev., *5*, 1941, 59.)

The strains isolated by Laidlaw and Elford (Proc. Roy. Soc. London, B, *120*, 1936, 292; *Sapromyces laidlawi A B* and *C*, Sabin, *loc. cit.*) and Seiffert (Cent. f. Bakt., I Abt., Orig., *139*, 1937, 337) according to Ørskov (Cent. f. Bakt., I Abt., Orig., *141*, 1938, 230) and Klieneberger (Jour. Hyg., *40*, 1940, 204) are closely similar to the organisms of the pleuropneumonia group. They are filterable, and the smallest reproductive units of those which we have appropriately examined were found to be between .125 and .175 micron. The colonies are similar in appearance to the colonies of the pleuropneumonia group.

The broth cultures consist of granules and round globular elements; the surface layer of agar colonies sometimes swells up into large round forms. They grow without serum, but small amounts of serum accelerate the growth. They grow both at 30° and at 37°C. and remain alive in cultures kept cold for several months. The broth cultures grow abundantly with a strong opalescence or sediment. Serologically the strains are distinct from the other members of the pleuropneumonia group and all but one are more or less similar to each other.

III. PLEUROPNEUMONIA-LIKE ORGANISMS ISOLATED FROM BACTERIAL CULTURES.

1. **Pleuropneumonia-like organisms isolated from Streptobacillus moniliformis.** L_1 (Klieneberger, Jour. Path. and Bact., *40*, 1930, 93; Jour. Hyg., *42*, 1942, 485; Dienes, Jour. Inf. Dis., *65*, 1939, 24; Jour. Bact., *44*, 1942, 37; *Musculomyces streptobacilli-moniliformis* Sabin, Bact. Rev., *5*, 1941, 57; Heilman, Jour. Inf. Dis., *69*, 1941, 32; Brown and Nunemaker, Bull. Johns Hopkins Hosp., *70*, 1942, 201.)

Cultures isolated from different strains

of *Streptobacillus moniliformis* vary considerably in the appearance of the colonies, the tendency to reversion to bacillary form, and the degree of autolysis. The colonies are considerably larger than the colonies of the human or animal pleuropneumonia-like strains; they may reach 1 to 2 mm. Usually a wide peripheral zone is present and development and autolysis of the large bodies produces a coarse appearance in the colonies. Sometimes no peripheral zone develops, the colony is dome-shaped, and the large bodies have no tendency to autolyze. The young colonies (twelve hours incubation) grow into the agar as loose strands of more or less swollen granules. Serum broth cultures grow in small clumps usually adhering to the wall of the test tube.

The cultures consist of small granules, small polar-staining bacilli and diphtheroid-like forms which swell to large round forms. In the top layer of fully developed colonies, the well-stained large bodies may be as large as 10 to 20 microns. By vacuolization they transform into empty blebs. By segmentation of their contents, the large forms may reproduce the small bacillary forms. In suitable preparations chromatin bodies are visible both in the small and large forms. The small forms are filterable through Berkfeld candles; the size of the smallest particles has not been exactly determined. The organism is very soft and fragile.

Their growth requirements and biochemical activities are similar to those of *Streptobacillus moniliformis*.

Growth occurs on nutrient agar containing animal serum or egg yolk. Sometimes there is a slight growth on boiled blood agar plates without serum. Good growth is obtained in a mineral solution with 0.1 per cent starch. Growth is both aerobic and anaerobic.

The L_1 form is more resistant to heat and to aging of the culture than is the streptobacillus and it has a remarkable resistance to penicillin to which the bacteria are very sensitive. Like the bacillus, L_1 produces acid but no gas from glucose, maltose, fructose, salicin, starch, and dextrin. It gives no oxidase test.

Serologically the L_1 form is similar to *Streptobacillus moniliformis* and different from the members of the pleuropneumonia group. It has no pathological effect on mice, rats or guinea pigs. It does not produce an infection of the chicken embryo. It can be isolated from freshly isolated strains of *Streptobacillus moniliformis*, from several-day old broth and agar cultures, from broth cultures heated at 56°C. and usually also from 48 hour agar cultures if they are incubated at 28° to 30°C. It is questionable whether the L_1 form has been isolated directly from rats.

Klieneberger (Jour. Hyg., *40*, 1940, 204) isolated a similar strain from a bacterium similar to *Streptobacillus moniliformis* which caused abscesses in guinea pigs. Whether this bacterium was identical or different from *Streptobacillus moniliformis* was not determined.

2. **Pleuropneumonia-like organisms isolated from Bacteroides funduliformis.** Dienes (Proc. Soc. Exp. Biol. and Med., *47*, 1941, 385) and Dienes and Smith (Jour. Bact., *48*, 1944, 125) isolated cultures from two strains of *Bacteroides funduliformis* which could be propagated indefinitely and which in morphology and in the appearance of colonies were closely similar to L_1.

The young colonies consisted of similar strands of granules growing into the medium. The surface of fully developed colonies consisted of large bodies and a honey-comb-like structure. The well isolated colonies grew usually to a fairly large size (1 to 2 mm).

Both strains, transplanted every two or three days through several months, failed to reproduce bacteria either on agar or submerged in broth.

No growth was obtained in liquid cultures.

The strains, like the parent organism, are strictly anaerobic and the cultures have the characteristic odor of the parent strain.

It was observed in slide cultures that the L type of colonies develop from large round forms which were produced in the cultures of the parent organism by gradual swelling of the bacteria.

In cultures of eight pleomorphic strains of *Bacteroides*, the L type of colonies developed in three strains under appropriate conditions. The bacteria swelled into large round bodies in all eight strains. The serological properties of the L strains have not thus far been studied. Neither the parent organisms nor the L type strains had any pathological effect on laboratory animals.

3. **Pleuropneumonia-like organisms in a species of Flavobacterium.** (Dienes, Jour. Bact., *44*, 1942, 37.)

Tiny colonies entirely similar in appearance to young L_1 colonies were isolated from the cultures of a species of *Flavobacterium*.

The bacterium when freshly isolated produced two types of colonies on blood agar plate; large colonies consisting of small regular bacilli and tiny colonies in which the bacteria became pleomorphic and swelled up to form large round bodies. The tiny colonies after 48 hours of incubation became autolyzed, and one or several L type of colonies started to grow under them. These colonies could be transplanted and gave abundant growth for two generations, but always died out in the third.

Bacterial forms were not reproduced either on agar or in broth.

The L type of growth was not pathogenic for mice though the parent organism was highly virulent.

4. **Development of tiny colonies in other bacteria.**

The development of tiny colonies similar in appearance to young colonies of the pleuropneumonia group has been observed in cultures of *Escherichia coli*, *Haemophilus influenzae*, and *Neisseria gonorrhoea* (Dienes, Jour. Bact., *44*, 1942, 37; Proc. Soc. Exp. Biol. and Med., *44*, 1940, 476). In all cases preceding their development, the organisms of the parent strains swelled into large round bodies, and in *Escherichia coli* and *Haemophilus influenzae* the development of the L type of colonies from these large forms was observed. Thus far these tiny colonies have not been isolated in pure cultures.
